PART II. PREPARATIONS AND COMPOSITIONS.

Containing those of the LONDON and EDINBURGH PHARMACOPOEIAS.

CHAP. I. *The more Simple Preparations.**The preparation of some substances not soluble in water. L.*

90

POUND these substances first in a mortar; then, pouring on a little water, levigate them on a hard and polished, but not calcareous, stone, that they may be made as fine as possible. Dry this powder on blotting-paper laid on chalk, and set it in a warm, or at least a dry, place, for some days.

In this manner are to be prepared,

Amber,

Antimony,

Calamine,

Chalk,

Coral,

Oyster-shells, first cleansed from their impurities,

Tutty.

Crabs claws, first broken into small pieces, must be washed with boiling water before they be levigated.

Verdegrise must be prepared in the same manner.

Where large quantities of the foregoing powders are to be prepared, it is customary instead of the stone and mallet, to employ hand-mills made for this purpose, consisting of two stones; the uppermost of which turns horizontally on the lower, and has an aperture in the middle, for supplying fresh matter, or of returning that which has already passed, till it be reduced to a proper degree of fineness.

For the levigation of hard bodies, particular care should be taken, whatever kind of instruments be used, that they may be of sufficient hardness, otherwise they will be abraded by the powders. The hematites, a hard iron one, is most conveniently levigated between two iron planes; for if the common levigating stones be used, the preparation, when finished will contain almost as much foreign matter from the instrument as the hematites.

It has been customary to moisten several powders in levigation, with rose, balm, and other distilled waters: these, nevertheless, have no advantage above common water, since in the subsequent exsiccation they must necessarily exhale, leaving the medicine possessed of no other virtue than what might be equally expected from it when prepared with the cheaper element.

Some few substances, indeed, are more advantageously levigated with spirit of wine than with water. Thus bezoar has the green colour usually expected in this costly preparation considerably improved thereby. A little spirit may be added to the other animal substances, if the weather be very hot, and large quantities of them are prepared at once, to prevent their running into putrefaction; an accident which in those circumstances sometimes happens when they are levigated with water only. Crabs-eyes, which abound with animal gelatinous matter, are particularly liable to this inconvenience.

The caution given above for reducing antimony, calamine, and tutty, to the greatest subtilty possible, demands particular attention. The tenderness of the parts to which the two last are usually applied, requires them to be perfectly free from any admixture of gross irritating particles. The first, when not thoroughly comminuted, might not only, by its sharp needle like spicula, wound the stomach, but likewise answer little valuable purpose as a medicine, proving either an useless load upon the viscera, or at best passing off without any other sensible effect than an increase of the grosser evacuations; while, if reduced to a great degree of fineness, it turns out a medicine of considerable efficacy.

The most successful method of obtaining these powders of the requisite tenuity, is, to wash off the finer parts by means of water, and continue levigating the remainder till the whole become fine enough to remain for some time suspended in the fluid; this process is received in the Edinburgh pharmacopœia, and there directed in the preparation of the following article.

Prepared antimony. E.

Let the antimony be first pounded in an iron mortar, and then levigated on a porphyry with a little water. After this, put it into a large vessel, and pour a quantity of water on it. Let the vessel be repeatedly shaken, that the finer part of the powder may be diffused through the water; the liquor is then to be poured off, and set by till the powder settles. The gross part, which the water would not take up, is to be further levigated, and treated in the same manner.

By this method, which is that commonly practised in the preparation of colours for the painter, powders may be obtained of any required degree of tenuity; and without the least mixture of the gross parts, which are always found to remain in them after long continued levigation; all the coarser matter settles at first, and the finer powder continues suspended in the water longer and longer, in proportion to the degree of its fineness. The same process may likewise be advantageously applied to other hard pulverifiable bodies of the mineral kingdom, or artificial preparations of them; provided they be not soluble in, or specifically lighter than, water. The animal and absorbent powders, crabs-claws, crabs-eyes, oyster shells, egg-shells, chalk, pearl, coral, and bezoar, are not well adapted to this treatment; nor indeed do they require it. These substances are readily soluble in acid juices without much comminution: if no acid be contained in the fluid passages, they are apt to congregate, with the mucus matter usually lodged there, into hard indissoluble masses: the greater degree of fineness they are reduced to, the more they are disposed to form such concretions, and become liable to obstruct the orifices of the small vessels.

92

Prepared calamine. E.

Calamine previously calcined for the use of those who make brasils, is to be treated in the same manner as antimony.

Prepared chalk.

- 93 Chalk first triturated, and then frequently washed with water, till it imparts to it neither taste nor colour, is to be treated in the same manner as antimony.

As calamine is intended for external application, and often the parts very easily irritated, too much pains cannot be believed in reducing it to a fine powder; and the frequent washing of the chalk may have the effect of freeing it from some foreign matters: But with regard to this substance, the latter part of the process, if not improper, is, in our opinion at least unnecessary: and this observation may also be made with respect to the oculi, or more properly lapilli, cancerorum, which the Edinburgh college direct to be treated in the same manner.

The preparation of hog's lard and mutton suet. L.

- 94 Cut them into pieces, and melt them over a slow fire; then separate them from the membranes by straining.

These articles had formerly a place also among the preparations of the Edinburgh college: But now they introduce them only into their list of the materia medica; as the apothecary will in general find it more for his interest to purchase them thus prepared, than to prepare them for himself: for the process requires to be very cautiously conducted, to prevent the fat from burning or turning black.

The purification of gum ammoniacum. L.

- 95 If gum ammoniac do not seem to be pure, boil it in water till it become soft; then squeeze it through a canvas bag, by means of a press. Let it remain at rest till the resinous part subside; then evaporate the water; and toward the end of the evaporation restore the resinous part, mixing it with the gummy.

In the same manner are purified assafoetida and such like gum resins.

You may also purify any gum which melts easily, such as Galbanum, by putting it in an ox-bladder, and holding it in boiling water till it be so soft that it can be separated from its impurities by pressing through a coarse linen cloth.

In straining all the gums, care should be taken that the heat be neither great nor long continued; otherwise a considerable portion of the more active volatile matter will be lost; an inconvenience which cannot by any care be wholly avoided. Hence the purer tears, unstrained, are in general to be preferred, for internal use, to the strained gums.

As an additional reason for this preference, we may add, that some of the gum-resins, purified in the common way, by solution in water, expression and evaporation, are not so easily soluble in aqueous menstrua after as before such depuration. On these accounts this process is entirely omitted by the Edinburgh college; and in every case where a gummy resinous substance, before it be taken, is to be dissolved in water,

it may be as effectually freed from impurities at the time of solution as by this process. And when it is to be employed in a solid state, care should be taken that the pure parts alone be selected.

The burning of hartshorn. L.

Burn pieces of hartshorn till they become perfectly white; then reduce them to a very fine powder. 96

The pieces of horn generally employed in this operation are those left after distillation.

In the burning of hartshorn, a strong fire and the free admission of air are necessary. The potter's furnace was formerly directed for the sake of convenience; but any common furnace or stove will do. If some lighted charcoal be spread on the bottom of the grate, and above this the pieces of the horn are laid, they will be burnt to whiteness, still retaining their original form.

Burnt hartshorn is not now considered as a pure earth, having been found to be a compound of calcareous earth and phosphoric acid. It is the weakest of the animal absorbents, and is difficultly soluble in acids; but whether it be of equal or superior use in diarrhoeas to more powerful absorbents, must be left to observation.

The drying of herbs and flowers.

Let these, spread out lightly, be dried by a gentle heat. L. 97

Herbs and flowers must be dried by a gentle heat, from a stove or common fire. They must be taken in such quantities at a time, that the process will be speedily finished; for by this means their medical powers are best preserved. The most certain test of this is the perfect preservation of the natural colour: but the leaves of cicuta, and of other plants containing a volatile matter, must be immediately pounded, after being dried, and afterwards kept in a phial with a ground stopper. E.

The directions given by the London college are here less explicit, and perhaps less proper, than those of the Edinburgh college: for there can be no doubt of the propriety of drying these substances hastily, by the aid of artificial heat, rather than by the heat of the sun. In the application of artificial heat, the only caution requisite is to avoid burning; and of this a sufficient test is afforded by the preservation of colour. And the direction given with regard to cicuta may perhaps with advantage be followed with most of the other flowers and herbs, afterwards to be exhibited in powder.

The purifying of honey. L.

Melt the honey by the heat of a water bath, and remove the scum. 98

The intention of this process is to purify the honey from wax, or other droffy matters that have been united with it by the violence of the press in its separation from the comb, and from meal and such like substances, which are sometimes fraudulently mixed with it. When the honey is rendered liquid and thin by the heat, these lighter matters rise freely to the surface,

This preparation is not so necessary for honey that is to be used as an article of diet, as for that which is employed

Preparations and Compositions.

employed in the preparation of oxymels: hence the Edinburgh college, who have rejected all the oxymels, have omitted this process.

The preparation of millipeds. L. E.

99 The millipeds are to be inclosed in a thin canvas cloth, and suspended over hot proof spirit in a close vessel, till they be killed by the steam, and rendered friable.

This is a convenient way of rendering millipeds pulverisable, without endangering any loss of such virtues as they may possess.

The directions given by both colleges are precisely the same, and delivered in almost the same words.

The extracting of pulps. L. E.

100 Unripe pulpy fruits, and ripe ones if they be dry are to be boiled in a small quantity of water until they become soft: then press out the pulp through a strong hair-sieve, and afterwards boil it down to the consistence of honey in an earthen vessel, over a gentle fire; taking care to keep the matter continually stirring, to prevent its burning.

The pulp of cassia fistularis is in like manner to be boiled out from the bruised pod, and reduced afterwards to a proper consistence, by evaporating the water.

The pulps of fruits that are both ripe and fresh, are to be pressed out through the sieve, without any previous boiling.

In the extraction of pulps, the direction of both colleges so nearly agree, that it is unnecessary to give a separate translation of each. We may only observe, that the London college, instead of softening the fruits by boiling them in a small quantity of water, direct them to be put in a moist place. This direction, though proper in some cases, is not generally the most suitable.

The drying of squills. L. E.

101 Let the squill, cleared from its outer skin, be cut transversely into thin slices, and dried with a very gentle heat. When properly managed, the squill is friable and retains its bitterness and acrimony.

By this method the squill dries much sooner than when its several coats are only separated, as has been usually directed; the internal part is here laid bare, but, in each of the entire coats, it is covered with a thin skin, which impedes the exhalation of the moisture. The root loses in this process four-fifths of its original weight; the parts which exhale appear to be merely watery: six grains of the dry root being equivalent to half a dram of the fresh; a circumstance to be particularly regarded in the exhibition of this medicine. In the preceding editions of our pharmacopœias, a particular caution was given, not to use an iron knife for cutting squills, but one of wood, ivory, or bone: the reason of this caution is said to be, not so much that the squill would receive any ill qualities from the iron; as, that its acrid juice, adhering to the knife, might render a wound received by it extremely painful, or even dangerous; but as no danger is to be apprehended from such an accident, the direction appears unnecessary. Dried squills furnish us with a me-

dicine, sometimes advantageously employed as an emetic, often as an expectorant, but still more frequently as a powerful diuretic.

Preparations and Compositions.

The burning of sponge.

Beat the sponge, after cutting it in pieces; and, when separated from its gritty matter, burn it in a close iron vessel, until it becomes black and friable; afterwards rub it to a very fine powder. *L.*

Put the sponge, cut into small pieces, and well freed from adhering earthy matters, into a close earthen vessel. Place it on the fire, and let it be stirred frequently till it become black and friable; then reduce it to a powder in a glass or marble mortar. *E.*

This medicine has been in use for a considerable time, and employed against scrofulous disorders and cutaneous foulness, in doses of a scruple and upwards. Its virtues seem to depend on a volatile salt just formed, and combined with its own oil. If the sponge be distilled with a strong heat, it yields a large proportion of that salt in its proper form. The salt is in this preparation so far extricated, that if the burnt sponge be ground in a brass mortar, it corrodes the metal so as to contract a disagreeable taint, and sometimes an emetic quality.

Bees, earthworms, and other animal substances, have by some been prepared in the same manner, and recommended in different diseases: but as these substances fall much short of sponge in the quantity of volatile salt producible from them by fire, they are probably inferior also in medicinal efficacy. Of all the animal matters that have been tried, raw silk is the only one which exceeds or equals sponge, in the produce of salt.

A good deal of address is requisite for managing this process in perfection. The sponge should be cut small, and beaten for some time in a mortar, that all the stony matters may be got out, which compared with the weight of the sponge when prepared, will sometimes amount to a considerable quantity. The burning should be discontinued as soon as the matter is become thoroughly black. If the quantity put into the vessel at once be large, the outside will be sufficiently burnt before the inside be affected; and the volatile salt of the former will in part escape, before that in the latter is begun to be formed. The best method of avoiding this inconvenience seems to be, to keep the sponge continually stirring, in such a machine as is used for the roasting of coffee.

And from this circumstance the iron vessel directed by the London college is preferable to the earthen one directed by that of Edinburgh. But the pounding in a glass or marble mortar, directed by the latter, is a necessary caution which the former college have omitted.

The purification of storax. L.

103 Dissolve the storax in rectified spirit of wine, and strain the solution; afterwards reduce it to a proper thickness with a gentle heat.

Storax was formerly directed to be purified by means of water; hence it was styled *storacis colatis*: but the method now adopted is much preferable, for the active parts

parts of the storax totally dissolve in spirit of wine, the impurities alone being left. And as these active parts do not rise in distillation, the spirit may be again recovered by distillation.

Purified filings of iron. E.

- 104 Apply a magnet to a sieve placed on filings of iron, so that the filings may be attracted upwards through the sieve.

Rust of iron, commonly called shavings of iron, prepared. E.

- 105 Set purified filings of iron in a moist place, that they may turn to rust, which is to be ground into an impalpable powder.

The cleansing of iron filings by means of a magnet is very tedious, and does not answer so well as might be expected; for if they are rusty, they will not be attracted by it, or not sufficiently: nor will they by this means be entirely freed from brass, copper, or other metallic substances which may adhere to them. It appears from the experiments of Henckel, that if iron be mixed by fusion with even its own weight of any of the other metals, regulus of antimony alone excepted, the compound will be vigorously attracted by the loadstone. The rust of iron is to be procured at a moderate rate from the dealers in iron, free from any impurities except such as may be washed off by water.

The rust of iron is by some preferred as a medicine to the calces or croci made by a strong fire. Hoffman relates, that he has frequently given it with remarkable success in obstinate chlorotic cases accompanied with excessive headachs and other violent symptoms; and that he usually joined with it pimpinella, arum root, and salt of tartar, with a little cinnamon and sugar. The dose is from four or five grains to twenty or thirty; some have gone as far as a dram: but all the preparations of this metal answer best in small doses, which should rather be often repeated than enlarged.

Scales of iron purified. E.

- 106 Let the scales of iron, which may be had at the anvils of the workmen, be purified by the magnet: for the magnet only attracts the smaller and purer parts, leaving the more thick and impure behind.

This is perhaps of all the forms the most eligible for obtaining the pure matter in such a divided state as to render it easily acted on by different menstrua; and the mode of purification here proposed is not only very effectual, but also very easily put into practice.

The extraction of mucilage. Gen.

- 107 Boil the gums or mucilaginous seeds in a sufficient quantity of water till it becomes viscid, nearly resembling the white of an egg; and then strain it by pressure through a linen cloth.

By this means vegetable mucilage may be easily obtained from many different substances in its pure state. And although this process is not directed in our pharmacopœias, yet we think that it might with advantage be adopted.

CHAP. II. *Of Conerves.*

CONSERVES are compositions of recent vegetable matters and sugar, beaten together into an uniform mass.

This management is introduced for preserving certain simples, undried, in an agreeable form, with as little alteration as possible in their native virtues; and to some subjects it is very advantageously applied. Vegetables, whose virtues are lost or destroyed by drying, may in this form be kept uninjured for a length of time: for by carefully securing the mouth of the containing vessel, the alteration, as well as dissipation, of their active principles, is generally prevented; and the sugar preserves them from the corruption which juicy vegetables would otherwise undergo. There are, however, sundry vegetables whose virtues are impaired by this treatment. Mucilaginous substances by long lying with sugar, become less glutinous; and astringents become sensibly foster on the palate. Many of the fragrant flowers are of so tender and delicate a texture, as almost entirely to lose their peculiar qualities on being beaten or bruised.

In general, it is obvious, that in this form, on account of the large admixture of sugar, substances of considerable activity can alone be taken to advantage as medicines. And, indeed, conerves are at present considered chiefly as auxiliaries to medicines of greater efficacy, or as intermedia for joining them to ether. They are very convenient for reducing into boluses or pills, the more ponderous powders as mercurius dulcis, the calces of iron and other mineral preparations; which with liquid or less consistent matters, as syrups, will not cohere.

The shops were formerly encumbered with many conerves altogether insignificant; the few now retained have in general either an agreeable flavour to recommend them, or are capable of answering some useful purposes as medicines. Their common dose is the bulk of a nutmeg, or as much as can be taken up at once or twice upon the point of a knife. There is in general no great danger of exceeding in this particular.

Conerves of wood sorrel;

sea wormwood;

the red rose;

the outer rind of the Seville orange. L.

Pluck the leaves from the stalks, the unblown petals from the cups, taking off the heels. Take off the outer rind of the oranges by a grater; then beat each of them with a wooden pestle in a marble mortar, first by themselves, afterwards with three times their weight of double refined sugar, until they be mixed.

Conerves of the fresh leaves of mint;

red roses not blown;

the outer rind of Seville oranges rasped off by a grater. E.

These are directed to be prepared with triple their weight of sugar in the same manner as the conerves of the London college. The sugar should be pounded by itself, and passed through a sieve before it be mixed with the vegetable mass; for without this it cannot

cannot be properly incorporated. Rose buds, and some other vegetables, are prepared for mixing with sugar by a small wooden mill contrived for that purpose.

In the same manner conserves may be prepared from many other vegetables. But besides the conserves for which general directions are given, there are others, for which, either on account of the particular mode of preparation, or of the proportion, our pharmacopœias have thought it necessary to give particular directions. But before taking notice of these, it is necessary to mention the medical properties of the conserves above enumerated.

Conserve of the leaves of wood-sorrel. L.

- 109 This is a very elegant and grateful conserve; in taste it is lightly acidulous, with a peculiar flavour, which some compare to that of green-tea. It is taken occasionally for quenching thirst, and cooling the mouth and fauces, in distempers where the heat of the body is much increased.

Conserve of the tops of sea wormwood. L.

- 110 The conserve of wormwood has been celebrated in dropics: Matthiolas relates, that several persons were cured by it of that distemper without the assistance of any other medicine. Where the disorder indeed proceeds from a simple laxity or flaccidity of the solids, the continued use of this medicine may be of some service; as it appears to be an elegant mild corroborant. It is directed to be given in the dose of half an ounce about three hours before meals.

Conserve of the buds of red roses. L. E.

- 111 This is a very agreeable and useful conserve. A dram or two dissolved in warm milk are frequently given as a light astringent, in weakness of the stomach, and likewise in coughs and phthical complaints. In the German ephemerides, examples are related of very dangerous phthises cured by the continued use of this medicine: In one of these cases, twenty pounds of the conserve were taken in the space of a month; and in another, upwards of thirty. Riverius mentions several other instances of this kind. There is, however, much room for fallacy in such observations; as phthisis has not at all times been accurately distinguished from obstinate catarrhs, and some other affections; the antiseptic property of the sugar may perhaps have some share in the effect.

Conserve of the yellow rind of Seville orange-peel. L. E.

- 112 This conserve is a very elegant one, containing all the virtues of the peel in a form sufficiently agreeable, both with regard to the dose and the conveniency of taking. It is a pleasant warm stomachic; and with this intention is frequently used.

Conserve of the leaves of spearmint. E.

- 113 The conserve of mint retains the taste and virtues of the herb. It is given in weakness of the stomach and retchings to vomit: and frequently does service in some cases of this kind, where the warmer and more active preparations of mint would be less proper.

Conserve of arum.

- 114 Take of the fresh root of arum bruised, half a pound;

double refined sugar, a pound and a half. Beat them together in a mortar.

The root of arum, in its recent state, is a substance of great activity; but this activity is almost entirely lost on drying. Hence the compound powder which had formerly a place in our pharmacopœias is now rejected. And as neither water nor spirit extract its activity, this conserve is perhaps the best form in which it can be preserved in our shops. It may be given to adults in doses of a dram.

Conserve of hips. L.

- Take of pulp of ripe hips one pound; double refined sugar, powdered, twenty ounces. Mix them into a conserve. 115

The conserve of hips is of some esteem as a soft cooling restringent; three or four drams or more are given at a time, in bilious fluxes, sharpness of urine, and hot indispositions of the stomach: A good deal of care is requisite on the part of the apothecary in making this conserve: the pulp is apt to carry with it some of the prickly fibres, with which the inside of the fruit is lined; if these be retained in the conserve, they will irritate the stomach, so as to occasion vomiting.

Conserve of sloes. L. E.

- Put the sloes in water upon the fire that they may soften, taken care that they be not broken; then, the sloes being taken out of the water, press out the pulp, and mix it with three times its weight of double-refined sugar into a conserve. 116

This preparation is a gentle astringent, and may be given as such in the dose of two or three drams. The degree of its astringency will vary according to the maturity of the sloes, and the length of time for which the conserve has been kept.

Conserve of squills.

- Take of fresh squills, one ounce; double-refined sugar, five ounces. Beat them together in a mortar into a conserve. 117

This conserve is directed to be prepared in a small quantity, to guard against its varying in strength. It may be given to adults from half a dram to two scruples, especially when fresh.

But the conserve of squills is a more uncertain and less agreeable mode of exhibiting this article, than the powder of the dried root, particularly when made into pills, or given in the form of bolus with any other conserve.

Conserve of chervil. Succ.

- Take of fresh leaves of chervil, double-refined sugar, each equal parts. Beat them together into a conserve. 118

Chervil has by some been extolled as an useful diuretic; and this is perhaps one of the most pleasant forms under which it can be exhibited.

Conserve of millepeds. Brun.

- Take of live millepeds, one pound; double refined sugar, two pounds and an half. Beat them together into a conserve. 119

If the millepeds possess those virtues which some have alleged, this is perhaps one of the best forms under

Prepara-
tions and
Composi-
tions.

der which they can be exhibited. And by children, to whom they are frequently prescribed, it may be easily taken, when other forms cannot be introduced.

Vitriolated conserve of roses. EMM.

120 To each pound of the conserve of roses add two drams of the diluted vitriolic acid.

This may be in some cases an useful means of increasing somewhat the astringency of the conserve of roses: But for the purposes for which the vitriolic acid is in general employed, the quantity that can thus be introduced is too inconsiderable to be of much service.

CHAP. III. *Of Juices,*

121

JUICES are obtained from the succulent parts of plants, by including them, after being properly cut, bruised, &c. in a hair bag, and pressing them, between wooden checks, in the common screw-press, as long as any liquor exudes.

The harder fruits require to be previously well beaten or ground; but herbs are to be only moderately bruised, for if these are over-bruised, a large quantity of the herbaceous matter will be forced out along with the juice. Hempen or woollen bags are apt to communicate a disagreeable flavour; the threads of these likewise swell in proportion as they imbibe moisture, so as in great measure to prevent the free percolation of the juice.

The fluids thus extracted from succulent fruits, both of the acid and sweet kind, from most of the acrid herbs, as scurvy grass and water-creffes, from the acid herbs, as sorrel and wood-sorrel, from the aperient lactescent plants, as dandelion and hawkweed, and from sundry other vegetables, contain great part of the peculiar taste and virtues of the respective subjects. The juices, on the other hand, extracted from most of the aromatic herbs as those of mint and the fragrant Turkey balm, commonly called *hain of Gilead*, have scarcely any thing of the flavour of the plants, and seem to differ little from decoctions of them made in water boiled till the volatile odorous parts has been dissipated. Many of the odoriferous flowers, as the lily, violet, hyacinth, not only impart nothing of their fragrance to their juice, but have it totally destroyed by the previous bruising. From want of sufficient attention to these particulars, practitioners have been frequently deceived in the effects of preparations of this class; juice of mint has been often prescribed as a stomachic, tho' it wants those qualities by which mint itself and its other preparations operate.

The juices, thus forcibly pressed out from plants, differ from those which flow spontaneously, or from incisions; these last consisting chiefly of such fluids as are not diffused through the whole substance of the vegetable subject, but elaborated in distinct vessels, or secreted into particular receptacles. From poppy heads, slightly wounded, there issues a thick milky liquor, which dries by a moderate warmth into opium; whilst the juice obtained from them by pressure is of a dark-green colour, and far weaker virtue.

Juices newly expressed are generally thick, viscid, and very impure: By colature, a quantity of gross matter is separated, the juice becomes thinner, limpid, and better fitted for medicinal purposes; though as yet

not entirely pure: on standing, it becomes again turbid, and apt to run into a fermentative or putrefactive state. Clarification with whites of eggs renders the juices more perfectly fine; but there are few that will bear this treatment without a manifest injury to their flavour, taste, and virtue.

The most effectual method of purifying and preserving these liquors, is to let the strained juices stand in a cool place till they have deposited their grosser feces, and then gently pass them several times through a fine strainer till perfectly clear; when about a fortieth part of their weight of good spirit of wine may be added, and the whole suffered to stand as before; a fresh sediment will now be deposited, from which the liquor is to be poured off, strained again, and put into small bottles which have been washed with spirit and dried. A little oil is to be poured on the surface, so as very nearly to fill the bottles, and the mouths closed with leather, paper, or stopped with straw, as the flasks in which Florence wine is brought to us: this serves to keep out dust, and suffers the air, which in process of time arises from all vegetable liquors, to escape; which air would otherwise endanger the bursting of the bottles; or, being imbibed afresh, render their contents vapid and foul. The bottles are to be kept on the bottom of a good cellar or vault, placed up to the necks in sand. By this method some juices may be preserved for a year or two; and others for a much longer time.

It has already been observed, that there are great difference in juices, in regard to their being accompanied in the expression with the virtues of the subjects. There are equal differences in regard to their preserving those virtues, and this independently of the volatility of the active matter, or its disposition to exhale. Even the volatile virtue of scurvy-grass may by the above method be preserved almost entire in its juice for a considerable time: while the active parts of the juice of the wild cucumber quickly separate and settle to the bottom, leaving the fluid part inert. Juices of arum root, iris root, bryony root, and sundry other vegetables, throw off in like manner their medicinal parts to the bottom.

Compound juice of scurvy-grass.

Take of the juice of garden scurvy-grass two pints; brook lime and water-creffes, of each one pint; Seville oranges, twenty ounces by measure. Mix them, and, after the feces have subsided, pour off the liquor, or strain it. *L.*

Take of juice of garden scurvy-grass, water-creffes, both expressed from the fresh herbs, Seville oranges, of each two pounds; spirituous nutmeg-water, half a pound. Mix them and let them stand till the feces have subsided, then pour off the clear liquor. *L.*

By this formula the Edinburgh college have rejected the brook-lime and the sugar of their former editions. The sugar was certainly a very improper addition; for though it may preserve dry vegetable matters, yet when added to juices largely impregnated with watery and mucilaginous matter, it would no doubt furnish that very principle most favourable to the production of the vinous fermentation. For the compound horse radish water they have substituted the spirituous water of nutmegs: Besides, that, this water has the same property

122

Preparations and Compositions.

of preserving the juices from fermentation: it is also much more agreeable to the palate, and will make the juices fit easier on the stomach.

The London college have retained nearly their former formula, giving it only a more proper name.

Both these compositions are of considerable use for the purposes expressed in the title: the orange juice is an excellent assistant to the scurvy-grafs and other acrid antiscorbutics; which, when thus mixed, have been found from experience to produce much better effects than when employed by themselves. These juices may be taken from an ounce or two to a quarter of a pint, two or three times a-day: they generally increase the urinary secretion, and sometimes induce a laxative habit. Preserved with the cautions above-mentioned, they will keep good for a considerable time; though, whatever care be taken, they are found to answer better when fresh: and from the difficulty of preserving them so, they have of late been very much laid aside, especially since we have been provided with more convenient and useful remedies.

INSPISSATED JUICES.

123

When vegetable juices, or watery or spiritous decoctions or infusions, are exposed to a continued heat, the fluid gradually evaporating, carries off with it such volatile matters as it was impregnated with, and leaves the more fixed united together into one mass. The mass which remains from the evaporation of the expressed juice of a plant is called *inspissated juice*; from watery decoctions or infusions, an *extract*; from spiritous tinctures, a *resin*, or *essential extract*. The term *extract* is frequently used also as a general appellation of all the three kinds. Inspissated juices and watery decoctions, particularly the former, when evaporated no further than to the consistence of oil or honey, are called *robs*; and spiritous tinctures, reduced to a like consistence, are called *balsams*.

What relates to the expression of juices has already been delivered, with the most effectual means of preserving them in their liquid state, and a general account of what substances do or do not give out their virtues with their juices. In the inspissation of juices, there is farther to be considered the volatility or fixity of their medicinal parts: if a plant loses its virtue, or part of its virtue, in being dried, it is obvious that the juice must lose as much in being inspissated to dryness, how gentle soever the heat be with which the inspissation is performed. It is likewise to be observed that the medicinal parts of some juices are kept in a state of perfect solution by the watery fluid, so as to be completely retained by it after the liquor has been made fine by settling, straining or other means; while the medicinal parts of others, not dissoluble by watery menstrua, are only diffused through the liquor in the same manner as the feculencies are, and separate along with these on standing.

Inspissated juice of the elder-berry. L.

124

Take of expressed and depurated juice of elder-berries two pints; inspissate it in a water bath, saturated with sea-salt.

Inspissated juice, commonly called rob of elder-berries. E.

VOL. XIV.

Take of juice of ripe elder-berries, five pounds: purified sugar, one pound. Evaporate with a gentle heat to the consistence of pretty thick honey.

This preparation, made with or without sugar, keeps well, and proves a medicine of considerable importance as an aperient, generally promoting the natural excretions by stool, urine, or sweat. The dose is from a dram or two to an ounce or more. A spoonful, diluted with water, is usually taken in common colds at bed-time.

Inspissated juice of wolfsbane. E.

Bruse the fresh leaves of aconitum; and including them in a hempen bag, strongly compress them in a press, so that they may give out their juice: let the juice be evaporated in open vessels in a water bath, to the consistence of pretty thick honey: An empyreuma is to be avoided by constantly stirring the mixture towards the end of the process.

After the matter has become cold, let it be put up in glazed earthen vessels, and moistened with rectified spirit of wine.

In the same manner are prepared inspissated juices of belladonna or deadly nightshade, and hyoscyamus or henbane.

In these inspissated juices, the active parts of the plant are obtained in a concentrated state, and in a condition which admits of preservation for a considerable length of time. They furnish, therefore, a convenient form for exhibiting these articles which, in the practice of medicine, are perhaps more frequently used in the state of inspissated juice than any other. This is particularly the case with the hyoscyamus, which may often be advantageously employed when opium is indicated, but disagrees with the patient. But aconite and belladonna may in general, with greater advantage, be exhibited under the form of powder made from the dried leaves.

It is very remarkable that the London college have given no place to these articles. We cannot however help thinking, that their pharmacopœia would be enriched by introducing not only the articles themselves, but likewise these preparations, especially as they are not unfrequently prescribed by British practitioners.

Inspissated juice of hemlock. E.

Having expressed the juice of the leaves and stalks of hemlock when flowering, in the same manner as directed for that of the aconitum, evaporate it to the consistence of pretty thin honey; when it is cooled, add of the powder of the dried leaves of the plant as much as to make it into a mass fit for forming pills. Care, however, is to be taken, that the evaporation proceed only to such length, that as much of the powder can be mixed with the inspissated juice as shall make up about a fifth part of the whole mass.

A preparation similar to this was published in Vienna by Dr Stoerk, who recommends it as an efficacious resolvent in many obstinate disorders, where the common remedies avail nothing. He observes, that small doses should always be begun with, as two grains, made into a pill twice a-day; and that by gradually increasing

R r

increasing

125

126

increasing the dose, it may be given to two, three, or even four drams a-day, and continued in such quantities for several weeks: that it may be used in safety in infancy, old age, and pregnancy: that it neither accelerates nor disturbs the circulation; neither heats, nor cools, nor affects the animal functions: that it increases the secretions, and renders the mouth moist; seldom purges; very rarely vomits; sometimes augments perspiration; often produces a copious discharge of viscid urine; but in many patients does not increase any of the sensible evacuations: that it removes obstructions and their consequences; relieves rheumatic pains, though of long continuance; dissolves scirrhous tumours, both internal and external; and cures dropsies and consumption, proceeding from scirrhotities: that it often dissolves cataracts, or stops their progress, and has sometimes removed the gutta serena: that inveterate cutaneous eruptions, scald heads, malignant ulcers, cancers, the malignant fluor albus and gonorrhœa of long standing, obstinate remains of the venereal disease, and caries of the bones, generally yield to it: that for the most part it is necessary to continue this medicine for a considerable time before the cure be effected, or much benefit perceived from it: that in some cases it failed of giving any relief; that he met with some persons who could not bear its effects: and that consequently there must be some latent difference in the habit, the diagnostic signs of which are at present unknown: that though it is by no means infallible any more than other medicines, yet the great number of deplorable cases that have been happily cured by it, is sufficient to recommend it to further trials. The efficacy of this medicine is confirmed by many eminent practitioners abroad; though the trials hitherto made of it in this country have not been attended with much success. Somewhat, perhaps, may depend on the time of the plant's being gathered, and the manner of the preparation of the extract. Dr Stoerk himself takes notice of some mistakes committed in this respect: some have left the herb in a heap for several days, whence part of it withered, part rotted, and the juice became thick and mucilaginous; others have taken a very large quantity of the juice, and boiled it down in copper vessels with a great heat; by which means a strong fetor was diffused to a considerable distance, and the most efficacious parts dissipated: others, with officious care, have clarified the juice, and thus obtained a black tenacious extract, retaining but a small degree of the specific smell of the plant. The extract duly prepared, according to the above prescription, is of a greenish brown colour, and a very disagreeable smell, like that of mace. But though there be reason to believe that much of the extract used here had been ill prepared, we can by no means admit that its general inefficacy was owing to this cause; for though there are not many instances of its discovering any valuable medicinal powers, there are several of its having activity enough, even in small doses, to produce alarming symptoms.

Modern practice, however, seems to hold a middle place; being neither influenced by the extravagant encomiums of Dr Stoerk, nor frightened by the wary suspicions of Dr Lewis. The inspissated juice of the henlock is accordingly given with freedom in a great

variety of complaints, without our experiencing the wonderful effects ascribed to it by the former, or the baneful consequences dreaded by the latter. Like other preparations of this valuable herb, it is no doubt a very useful addition to our pharmacopœia; nor does its use seem to be more hazardous than that of opium and some other narcotics.

The London college direct the inspissated juice of cicuta to be prepared in the same manner as that of the elder-berry, and without the addition of any of the powder. This is the most pure extract; and the powder may easily be occasionally added. They direct the cicuta to be collected as soon as the flowers appear: And at that time the leaves are most fully impregnated with their active powers.

Inspsissat. d juice of black currants. L.

Inspsissated juice of lemons. L.

These two the London college also direct to be prepared in the same manner with the elder-berry juice. And under this form the agreeable and useful acid of these vegetables, in a concentrated state, may be preserved for a considerable length of time.

CHAP. IV. *Extracts and Resins.*

Observations on Extracts with Water.

These extracts are prepared by boiling the subject in water, and evaporating the strained decoction to a thick consistence.

This process affords us some of the more active parts of the plants, free from the useless indissoluble earthy matter, which makes the largest share of their bulk. There is a great difference in vegetable substances, with regard to their fitness for this operation; some yielding to it all its virtues, and others scarce any. Those parts in which the sweet glutinous, emollient, cooling, bitter, austere, astringent virtues reside, are for the most part totally extracted by the boiling water, and remain almost entire on evaporating it: whilst those which contain the peculiar odour, flavour, and aromatic quality, are either not extracted at all, or exhale along with the menstruum. Thus gentian root, which is almost simply bitter, yields an extract possessing in a small volume the whole taste and virtues of the root.—Wormwood, which has a degree of warmth and strong flavour joined to the bitter, loses the two first in the evaporation, and gives an extract not greatly different from the foregoing: the aromatic quality of cinnamon is dissipated by this treatment, its astringency remaining; while an extract made from the flowers of lavender and rosemary discovers nothing either of the taste, smell, or virtues of the flowers.

General Rules for making Extracts with Water.

1. It is indifferent, with regard to the medicine, whether the subject be used fresh or dry; since nothing that can be preserved in this process will be lost by drying. With regard to the facility of extraction, there is a very considerable difference; vegetables in general giving out their virtues more readily when moderately dried than when fresh.

2. Very

Preparations and Compositions.

2. Very compact dry substances should be reduced into exceeding small parts, previous to the affusion of the menstruum.

3. The quantity of water ought to be no greater than is necessary for extracting the virtues of the subject. A difference herein will sometimes occasion a variation in the quality of the product; the larger the quantity of the liquor, the longer time will be requisite for evaporating it, and consequently the more volatile parts of the subject will be dissipated. A long-continued heat likewise makes a considerable alteration in the matter which is not volatile. Sweet substances, by long boiling with water, become nauseous; and the drastic purgatives lose their virulence, though without any remarkable separation of their parts.

4. The decoctions are to be depurated by colature; and afterwards suffered to stand for a day or two, when a considerable quantity of sediment is usually found at the bottom. If the liquor poured off clear be boiled down a little, and afterwards suffered to cool again, it will deposit a fresh sediment, from which it may be decanted before you proceed to finish the evaporation. The decoctions of very resinous substances do not require this treatment, and are rather injured by it; the resin subsiding along with the inactive dregs.

5. The evaporation is most conveniently performed in broad shallow vessels; the larger the surface of the liquor, the sooner will the aqueous parts exhale: This effect may likewise be promoted by agitation.

6. When the matter begins to grow thick, great care is necessary to prevent its burning. This accident almost unavoidable if the quantity be large, and the fire applied as usual under the evaporating pan, may be effectually provided against, by carrying on the inspissation after the common manner, no farther than to the consistence of a syrup, when the matter is to be poured into shallow tin or earthen pans, and placed in an oven with its door open, moderately heated; which acting uniformly on every part of the liquid, will soon reduce it to any degree of consistence required. This may likewise be more securely done, by setting the evaporating vessel in boiling water, but the evaporation is in this way very tedious.

Observations on Extracts with Rectified Spirit.

Rectified spirit of wine dissolves the essential oils and resins of vegetables, and does not readily carry off the oil in its exhalation; the heat sufficient to exhale pure spirit being much less than that in which water evaporates to any considerable degree, or most essential oils distil. Hence a resinous or spirituous extract of wormwood, contrary to that made with water contains the warmth and flavour, as well as bitterness, of the herb; one made from cinnamon possesses its aromatic virtue, as well as its astringency; and one from lavender and rosemary flowers, retains great part of their flavour and virtues; the volatile parts, which are carried off by water in its evaporation, being left behind by the spirit.

The spirit employed for this purpose should be perfectly free from any ill flavour, which would be communicated in part to the preparation; and from any admixture of phlegm or water, which would not only

vary its dissolving power, but likewise, evaporating towards the end of the inspissation would promote the dissipation of the volatile parts of the subject. Hence also, the subject itself ought always to be dry: those substances which lose their virtue by drying, lose it equally on being submitted to this treatment with the purest spirit.

The inspissation should be performed from the beginning, in the gentle heat of a water bath. It is not needful to suffer the spirit to evaporate in the air; greatest part of it may be recovered by collecting the vapour in common distilling vessels. If the distilled spirit be found to have brought over any flavour from the subject, it may be advantageously reserved for the same purposes again.

It is observable, that though rectified spirit be the proper menstruum of the pure volatile oils, and of the grosser resinous matter of vegetables, and water of the mucilaginous and saline; yet these principles are, in almost all plants, so intimately combined together, that whichever of these liquors is applied at first, it will take up a portion of what is directly soluble only in the other. Hence sundry vegetables, extremely resinous, and whose virtues consist chiefly in their resin, afford nevertheless very useful extracts with water, though not equal to those which may be obtained by a prudent application of spirit. Hence also the extracts made from most vegetables by pure spirit, are not mere resins; a part of the gummy matter, if the subject contained any such, is taken up along with the resin; an admixture of great advantage to it in a medicinal view. The spirituous extracts of several vegetable substances, as mint leaves, rhubarb, saffron, dissolve in water as well as in spirit.

Pure resins are prepared by mixing, with spirituous tincture of very resinous vegetables, a quantity of water. The resin, incapable of remaining dissolved in the watery liquor, separates and falls to the bottom; leaving in the menstruum such other principles of the plant as the spirit might have extracted at first along with it.

Observations on Extracts with Spirit and Water.

There are sundry vegetables, particularly those of a resinous nature, which are treated to better advantage with a mixture of water and spirit, than with either of them singly. The virtues of resinous woods, barks, and roots, may indeed be in great part extracted by long boiling in fresh portions of water; but at the same time they suffer a considerable injury from the continued heat necessary for the extraction, and for the subsequent evaporation of so large a quantity of the fluid. Rectified spirit of wine is not liable to this inconvenience; but the extracts obtained by it from the substances here intended, being almost purely resinous, are less adapted to general use than those in which the resin is divided by an admixture of the gummy matter, of which water is the direct menstruum.

There are two ways of obtaining these compound or gummy-resinous extracts: one, by using proof spirit, that is, a mixture of about equal parts of spirit and water, for the menstruum; the other, by digesting the subject first in pure spirit and then in water, and afterwards uniting into one mass the parts which

the two menstrua have separately extracted. In some cases, where a sufficiency of gummy matter is wanting in the subject, it may be artificially supplied, by inspissating the spirituous tincture to the consistence of a balsam, then thoroughly mixing with it a thick solution of any simple gum, as mucilage of gum-arabic, and drying the compound with a gentle heat. By this method are obtained elegant gummy resins, extemporaneously miscible with water into milky liquors.

Observations on extracts by long digestion.

- 132 It has been observed, that the virtues of vegetable decoctions are altered by long boiling. Decoctions or infusions of drastic vegetables, by long continued boiling or digestion, lose more and more of their virulence; and at the same time deposit more and more of a gross sediment, resulting probably from the decomposition of their active parts. On this foundation it has been attempted to obtain safe and mild preparations from sundry virulent drugs; and some of the chemists have strongly recommended the process, though without specifying, or giving any intimation of, the continuance of boiling requisite for producing the mildness in different subjects. M. Beaumé in his *Element de pharmacie*, lately published, has given a particular account of an extract of opium prepared on this principle; of which extract, as it is alleged to be very useful in practice, it may not be improper to give a short description: And this we shall accordingly subjoin to our account of the opium purificatum of the London college.

Observations on particular extracts.

- 133 *Extract of chamomile,*
broom tops,
gentian,
liquorice,
black hellebore,
rue,
favix. L.

Boil the article in distilled water, press out the decoction, strain it, and set it apart that the feces may subside; then boil it again in a water-bath saturated with sea-salt to a consistence proper for making pills.

The same kind of bath is to be used in the preparation of all the extracts, that the evaporation may be properly performed.

Extract of gentian. E.

- 134 Take of gentian root as much as you please. Having cut and bruised it, pour upon it four times its quantity of water. Boil to the consumption of one half of the liquor; and strongly expressing it, strain. Evaporate the decoction to the consistence of thick honey in vessels exposed to the vapour of hot water.

In preparing this and every other extract, it is necessary to keep up a constant stirring towards the end of the process, in order to prevent an empyreuma, and that the extract may be of an uniform consistence, and free of clots.

In the same manner are prepared,

Extract of the roots of black hellebore;
 leaves of the pulsatilla nigricans;
 leaves of rue;
 leaves of white poppies;
 imperfectly ripe seeds of hemlock.

All the above extracts contain the virtues of the vegetable in a state of tolerable perfection.

The extract of chamomile loses in its formation the specific flavour of the plant; but it is said to furnish a bitter remarkably antiseptic, and to be given with advantage in different stomach ailments to the extent of a scruple or two, either by itself, or in conjunction with other remedies. The extract of broom tops is chiefly employed in hydropic cases; and when taken to the quantity of about a dram, is said to operate as a powerful diuretic.

The mode of preparing these extracts directed by the London and Edinburgh colleges is not essentially different; but some advantage will arise from employing the distilled water directed by the former; and the directions given by the latter with regard to the quantity of water to be used, and the degree of boiling to be employed before expression, are not without some use.

The extract is the only preparation of the pulsatilla nigricans, and it seems sufficiently well suited to be brought into this form. The extract of the white poppy-heads is not perhaps superior in any respect to opium; but to those who may think otherwise, it is convenient to preserve them in this form for preparing the syrup occasionally. The seeds of hemlock have by some been thought stronger, or at least that they produce giddiness sooner, than the leaves; but this extract has not hitherto come into general use.

Compound extract of coloquintida. L.

135 Take of pith of coloquintida, cut small, six drams; scotoryne aloes, powdered, an ounce and a half; scammony, powdered, half an ounce; smaller cardamom seeds, husked and powdered, one dram; proof-spirit, one pint. Digest the coloquintida in the spirit, with a gentle heat, during four days. To the expressed tincture add the aloes and scammony; when these are dissolved, distil off the spirit, so that what remains may be of a consistence proper for making pills, adding the seeds towards the end of the process.

This composition answers very effectually as a cathartic, so as to be relied on in cases where the patient's life depends on that effect taking place; the dose is from fifteen grains to half a dram. The proof spirit is a very proper menstruum for the purgative materials; dissolving nearly the whole substance of the aloes and scammony, except the impurities; and extracting from the colocynth, not only the irritating resin, but great part of the gummy matter. In the former pharmacopœias three spices were employed in this composition, cinnamon, mace, and cloves; the cardamom seeds, now introduced, are preferable on account of their aromatic matter being of a less volatile nature; though a considerable part of the flavour, even of these, is dissipated during the evaporation of the phlegmatic part of the proof-spirit.

Eluterium. L.

136 Slit ripe wild cucumbers, and pass the juice, very lightly

lightly pressed, through a fine hair sieve, into a glass vessel; then set it by for some hours until the thicker part has subsided. Pour off the thinner part swimming at the top, and separate the rest by filtering: cover the thicker part, which remains after filtration, with a linen cloth, and dry it with a gentle heat.

What happens in part in preparing the extract of hemlock, happens in this preparation completely, viz. the spontaneous separation of the medicinal matter of the juice on standing for a little time: and the case is the same with the juices of several other vegetables, as those of arum root, iris root, and bryony root. Preparations of this kind have been commonly called *fecula*. The filtration above directed, for draining off such part of the watery fluid as cannot be separated by decantation, is not the common filtration through paper, for this does not succeed here: the grosser parts of the juice, falling to the bottom, form a viscid cake upon the paper, which the liquid cannot pass through. The separation is to be attempted in another manner, so as to drain the fluid from the top: this is effected by placing one end of some moistened strips of woollen cloth, skains of cotton, or the like, in the juice, and laying the other end over the edge of the vessel, so as to hang down lower than the surface of the liquor: by this management the separation succeeds in perfection.

Elaterium is a very violent hydragogue cathartic. In general, previous to its operation, it excites considerable sickness at the stomach, and not unfrequently it produces severe vomiting. Hence it is seldom employed till other remedies have been tried in vain. But in some instances of ascites it will produce a complete evacuation of water where other cathartics have had no effect. Two or three grains are in general a sufficient dose. And perhaps the best mode of exhibiting it is by giving it only to the extent of half a dram at a time, and repeating that dose every hour till it begins to operate.

Extract of logwood. L.

137 Take of shavings of logwood, one pound. Boil it four times, or oftener, in a gallon of distilled water, to one half; then, all the liquors being mixed and strained, boil them down to a proper consistence.

The extract of logwood has been used for a considerable time in some of our hospitals. It has an agreeable sweet taste, with some degree of astringency; and hence becomes serviceable in diarrhœas, for moderately constringing the intestines and orifices of the smaller vessels: it may be given from a scruple to half a dram, and repeated five or six times a-day with advantage. During the use of this medicine, the stools are frequently tinged red by it, which has occasioned some to be alarmed as if the colour proceeded from blood: the practitioner therefore ought to caution the patient against any surprise of this kind.

The active parts of the logwood are difficultly extracted by means of water alone: hence the Edinburgh college call in the aid of spirit of wine, directing this extract to be prepared in the same manner as that of jalap, afterwards to be mentioned. And of the two modes, we are inclined to consider the latter as intitled to the preference.

Extract of Peruvian bark. L.

Take of Peruvian bark, coarsely powdered, one pound; distilled water, 12 pints. Boil it for one or two hours, and pour off the liquor, which, while hot, will be red and pellucid; but, as it grows cold, will become yellow and turbid. The same quantity of water being again poured on, boil the bark as before, and repeat this boiling until the liquor, being cold, remains clear. Then reduce all these liquors, mixed together and strained, to a proper thickness, by evaporation.

This extract must be prepared under two forms; one *soft*, and fit for making pills; the other *hard*, that it may be reducible to a powder.

Extract of Peruvian bark with the resin. L.

Take of Peruvian bark, reduced to coarse powder, one pound; rectified spirit of wine, four pints. Digest it for four days, and pour off the tincture; boil the residuum in 10 pints of distilled water to two; then strain the tincture and decoction separately, evaporating the water from the decoction, and distilling off the spirit from the tincture, until each begins to be thickened. Lastly, mix the resinous with the aqueous extract, and make the mass fit for forming into pills.

Extract of Peruvian bark. E.

The Edinburgh college, who have not given a place to any pure watery extract of the bark, direct their extract of this medicine to be prepared in the same manner as their extract of jalap, that is, almost precisely in the same manner as the extract with resin of the London college. It is, however, we think with propriety, that the London college have given a place to both extracts; for neither is without its use.

Peruvian bark is a resinous drug; the resin melts out by the heat, but is not perfectly dissolved by the water; hence, in cooling, it separates, renders the liquor turbid, and in part falls to the bottom, as appears manifestly upon examining the sediment by spirit of wine. This extract might be made to better advantage by the assistance of spirit of wine, after the same manner as that of jalap; and this method the Edinburgh college have directed. But all the spirits which can be expected to be employed for this process among us, are accompanied with some degree of bad flavour; this adheres most strongly to the phlegmatic part of the spirit, which evaporating last, must communicate this ill flavour to the extract; a circumstance of very great consequence, as this medicine is designed for those whose stomachs are too weak to bear a due quantity of bark in substance. Ten or twelve grains of the hard extract are reckoned equivalent to about half a dram of the bark itself.

In the Peruvian bark, however, we may readily distinguish two different kinds of tastes, an astringent and a bitter one; the former seems to reside principally in the resinous matter, and the latter chiefly in the gummy. The watery extract is moderately strong in point of bitterness, but of the astringency it has only a small degree. The pure resin, on the other hand, is strong in astringency, and weak in bitterness. Both qualities.

Preparations and Compositions.

are united in the extract with the resin; which appears to be the best preparation of this kind that can be obtained from this valuable drug.

Extract of cascarilla. L.

141

This extract, which is now for the first time introduced into the pharmacopœia of the London college, and which has not yet obtained a place in that of Edinburgh, is directed to be prepared by spirit and water in the same manner as the extract of bark with the resin. It possesses, in a concentrated state, the active constituent parts of the cascarilla, and has accordingly been already received into several of the best foreign pharmacopœias. In some of these, as the pharmacopœia Suecica, it is a mere watery extract: but in others, as the Pharmacopœia Rossica, the aid both of spirits and water are conjoined; and this we consider as the best preparation.

Extract of jalap. E.

142

Take of jalap root one pound; rectified spirit of wine, four pounds. Digest four days, and pour out the tincture. Boil the remaining magma in ten pounds of water to two pounds; then strain the decoction, and evaporate it to the consistence of pretty thin honey. Draw off the spirit from the tincture by distillation till what remains becomes thick. Then mix the liquors thus inspissated; and keeping them constantly stirring, evaporate to a proper consistence.

The extract of jalap is directed to be prepared by the London college in the same manner as their extract of Peruvian bark with the resin, which differs in nothing from the mode of preparation above directed.

This extract is an useful purgative; by some thought preferable to the crude root, as being of more uniform strength, and as the dose, by the rejection of the woody parts, is rendered smaller: the mean dose is 12 grains. If the spirituous tincture were inspissated by itself, it would afford a resinous mass, which, unless thoroughly divided by proper admixtures, occasions violent griping, and yet does not prove sufficiently cathartic: the watery decoctions yield an extract which operates very weakly: both joined together, as in this preparation, compose an effectual and safe purge. This method of making extracts might be advantageously applied to several other resinous substances, as the dry woods, roots, bark, &c. A small quantity of spirit takes up the resin; and much less water than would otherwise be necessary, extracts all the other soluble parts.

In a former edition of the Edinburgh Pharmacopœia, a little fixed alkaline salt was ordered to be added to the water in which the jalap is boiled after the action of spirit; on a supposition that this would enable the water to extract more from the root than it could by itself. But, so far as the quantity of the alkaline salt could go, it had the opposite effect, impeding the action of the water. The resinous parts of the jalap are dissolved by the spirit; and little other than the gummy matter remains for water to extract. Now, if pure gum arabic be put into water along with any alkaline salt, the salt will render the water incapable of dissolving the gum: if the gum be dissolved

first, the addition of any alkaline salt will precipitate it.

Extract of senna. L.

Preparations and Compositions.

143

Take of senna, one pound; distilled water, one gallon. Boil the senna in the distilled water, adding after its decoction a little rectified spirit of wine. Evaporate the strained liquor to a proper thickness.

This extract had no place in our former pharmacopœias, but may be considered as an useful addition.

The resinous parts of senna are in so small a proportion to the gummy, that they are readily boiled out together. The spirit may be added when the decoction is reduced to one half or to three pints.

This extract is given as a gentle purgative from 10 grains to a scruple; or, in less quantity, as an assistant to the milder laxatives.

Purified opium. L.

144

Take of opium, cut into small pieces, one pound; proof spirit of wine, 12 pints. Digest the opium with a gentle heat, stirring now and then till it be dissolved, and filter through paper. Distil the tincture so prepared, to a proper thickness.

Purified opium must be kept in two forms; one *soft*, proper for forming into pills; the other *hard*, which may be reduced into powder.

Opium was formerly purified by means of water; and in this state it had the name in our pharmacopœia of *extractum thebaicum*. But proof-spirit has been found, by experiments, to be the best menstruum for opium, having dissolved three-fourths of dried opium, which was much more than was taken up either by rectified spirit or water. Hence we thus obtained most entirely the constituents of opium free from any adhering impurities: but it has been imagined that some particular advantages arise from the parts which are extracted by water, especially after long digestion; and accordingly the following extract of opium has been recommended by Mr Beaumé.

Extract of opium prepared by long digestion.

145

Let five pounds of good opium, cut in pieces, be boiled about half an hour, in 12 or 15 quarts of water: strain the decoction, and boil the remainder once or twice in fresh water, that so much of the opium as is dissoluble in water may be got out. Evaporate the strained decoction to about six quarts; which being put into a tin cucurbit, placed in a sand-bath, keep up such a fire as may make the liquor nearly boil, for three months together if the fire is continued day and night, and for six months if it is intermitted in the night; filling up the vessel with water in proportion to the evaporation, and scraping the bottom with a wooden spatula from time to time, to get off the sediment which begins to precipitate after some days digestion. The sediment needs not to be taken out till the boiling is finished; at which time the liquor is to be strained when cold, and evaporated to an extract of a due consistence for being formed into pills.

The author observes, that by keeping the liquor strongly boiling, the tedious process may be considerably expedited, and the six months digestion reduced

Prepara-
tions and
Composi-
tions.

to four months: that in the beginning of the digestion, a thick, viscous, oily matter rises to the top, and forms a tenacious skin as the liquor cools; this is supposed to be analogous to essential oils, though wanting their volatility: that the oils begins to disappear about the end of the first month, but still continues sensible till the end of the third, forming oily clouds as often as the liquid cools: that the resin at the same time settles to the bottom in cooling, preserving for a long while its resinous form, but by degrees becoming powdery, and incapable of being any longer softened, or made to cohere by the heat; that when the process is finished, part of it still continues a perfect resin, dissoluble in spirit of wine, and part an indissoluble powder: that when the digested liquor is evaporated to about a quart, and set in the cold till next day, it yields a brownish earthy saline matter, called the *essential salt of opium*, in figure nearly like the sedative salt obtained from borax, intermingled with small needled crystals. He gives an account of his having made this preparation six or seven times. The vessel he made use of was about two inches and a half diameter in the mouth; the quantity of water evaporated was about 24 ounces a day, and from 130 to 140 quarts during the whole digestion. Out of 64 ounces of opium, 17 ounces remained undissolved in the water; the quantity of resinous matter precipitated during the digestion, was 12 ounces: from the liquor, evaporated to a quart, he obtained a dram of essential salt, and might, he says, have separated more; the liquor being then further evaporated to a pilular consistence, the weight of the extract was 31 ounces.

It is supposed that the narcotic virtue of opium resides in the oily and resinous parts; and that the gummy extract, prepared by the above process, is endowed with the calming, sedative or anodyne powers of the opium, divested of the narcotic quality as it is of the smell, and no longer productive of the disorders which opium itself, and the other preparations of it, frequently occasion. A case is mentioned, from which the innocence and mildness of the medicine are apparent; 50 grains having been taken in a day, and found to agree well, where the common opiate preparations could not be borne. But what share it possesses of the proper virtues of opium is not so clear; for the cure of convulsive motions of the stomach and vomitings, which at length happened after the extract had been continued daily in the above doses for several years (*plusieurs années*), cannot perhaps be ascribed fairly to the medicine.

If the theory of the process, and of the alteration produced by it in the opium, be just, a preparation equivalent to the above may be obtained in a much shorter time. If the intention is to separate the resinous and oily parts of opium, they may be separated by means of pure spirit of wine, in as many hours as the digestion requires months. The separation will also be as complete in regard to the remaining gum, tho' some part of the gum will in this method be lost, a little of it being taken up by the spirit along with the other principles.

In what particular part of opium its peculiar virtues reside, has not perhaps been incontestably ascertained; but this much seems clear from experiment, that the pure gum, freed from all that spirit can dissolve, does

not differ essentially in its soporific power from the resinous part.

There are grounds also to presume, that by whatever means we destroy or diminish what is called the *narcotic, soporific, virulent quality of opium*, we shall destroy or diminish likewise its salutary operation. For the ill effects which it produces in certain cases, seem to be no other than the necessary consequences of the same power, by which it proves so beneficial in others.

Extract of wormwood. Succ.

Take any quantity of the tops of wormwood, and pour upon it double its weight of water. Boil it for a short time over a gentle fire, then press out the liquor. Boil the residuum again in a fresh quantity of water, and after expression, strain it. Let the strained liquor be evaporated in a water-bath to a proper consistence.

In this extract we have one of the strongest vegetable bitters in its most concentrated state: and though it is not perhaps to be considered as superior to the extract of gentian, yet it furnishes a good variety, and is a more agreeable form for exhibiting the wormwood than that of strong tincture.

Extract of dandelion. Succ.

This is directed to be prepared from the roots of the dandelion, collected early in the spring, or late in the autumn, in the same manner as the extractum absinthii. And as far as the dandelion really possesses a resolvent, aperient, or diuretic power, it furnishes a convenient form for obtaining these effects from it. But as the dandelion is well known to abound with a milky juice, it is probable that the activity of the medicine would be increased from employing spirit also in the extraction of its medical virtues.

Watery extract of aloes. Succ.

Take of hepatic aloes one pound; cold spring water, four pounds; juice of citrons, one pound. Macerate them in a glass vessel for one or two days, shaking the vessel from time to time. When the resinous and feculent parts have subsided, pour off the liquor: and to the residuum add fresh water, till by this treatment it obtains a little impregnation. Let the strained liquors be then evaporated in a warm bath to the consistence of honey.

Although aloes are perhaps upon the whole a better medicine, in their crude state, where the gummy and resinous matters are united, than in those preparations where either is retained separately, yet the gummy extract which is thus obtained is at least less disagreeable having little smell or taste, while at the same time it is a very powerful purgative: hence it may be usefully employed at least on some occasions.

Gummy extract of myrrh. Brun.

Take of myrrh, half a pound; spring water, four pounds. Let the myrrh be dissolved by gentle digestion and repeated agitation of the vessel for four or five days: let the water swimming above the myrrh be then pured off, strained, and evaporated to the consistence of an extract.

This

147

148

149

This watery extract of myrrh may be useful in some cases, as being much deprived of the heating qualities which it has in its crude state: and if it furnishes us in phthisis pulmonalis with that useful remedy which some imagine, it may probably be most advantageously exhibited under this form.

Refined liquorice. Dan.

150 Take any quantity of Spanish liquorice, cut it into small fragments, dissolve it in tepid water, and strain the solution. Let the liquor be poured off from the feculent part after it has subsided, and inspissated by a gentle heat.

The extract of liquorice already mentioned, when it is prepared with due skill and attention, is unquestionably an article superior to this; but it is very rarely met with in the shops of our druggists or apothecaries as prepared by themselves. In its place they very commonly employ either the extract brought from Spain, or that prepared by the makers of liquorice at home; both of which very commonly abound with impurities. It has even been said, that a portion of sand is not unfrequently mixed with it to increase the weight: but whether the impurities arose from this cause, or from the slovenly mode of preparing it, considerable advantage must arise from freeing it from all these before it be employed for any purpose in medicine. And in modern practice it is frequently used, not only in troches and pills, but also for suspending powders in waters; such as the powder of Peruvian bark: and the powder of bark, when thus suspended, is in general taken more readily by children than in any other form. Hence considerable advantage must arise from a proper and easy mode of purifying it, which the above process affords. We are of opinion, therefore, that although a place be with propriety given to the extract of liquorice prepared by the apothecaries themselves, refined liquorice ought also to be introduced into our pharmacopœias; and it would be very convenient to keep it in the shops in a soft consistence fit for making pills, as it would not only answer that purpose but admit of a ready solution in water when requisite. To this consistence, indeed an objection occurs, from its being apt to grow mouldy; but this may be effectually prevented by the addition of a small proportion of spirit.

Besides the extracts which we have here selected from the foreign pharmacopœias, many others also still retain a place in several of these; such, for example, as the *extractum arnicæ, artemisicæ, Lyoniæ, cardui, cestauri, cochleariæ, croci*, &c. Several of these had formerly a place in our pharmacopœias, but are now with propriety rejected; because, where these substances are to be employed, they may with much more advantage be exhibited under other forms. And, indeed, although under the form of extract we have a condensation of some active principles, yet by the action of fire others are very apt to be lost. Hence, where any article can be conveniently exhibited in substance, that form is in general preferable; and recourse should be had to extracts only with a view to some particular intention. Our colleges therefore have with propriety diminished the number of them; and even those which they have adopted are but seldom to be had recourse to in preference to other forms. In the formation of many of

those extracts, retained by the foreign colleges, the most valuable principles are either entirely dissipated or destroyed by the fire. We think, however, that advantage may sometimes be obtained from adopting these which are here selected.

The chapter on extracts and resins in the London pharmacopœia is concluded with the two following general directions:

1. All the extracts, during the time of inspissation must be gently agitated.
2. On all the softer watery extracts, a small quantity of spirit of wine must be sprinkled

CHAP. V. *Expressed Oils.*

EXPRESSED oils are obtained chiefly from certain seeds and kernels of fruits, by thoroughly pounding them in a stone mortar, or, where the quantities are large, grinding them in mills, and then including them in a canvas bag, which is wrapt in a hair-cloth, and strongly pressed between iron plates. The canvas, if employed alone, would be squeezed so close to the plates of the press as to prevent the oil from running down: by the interposition of the hair-cloth a free passage is allowed it.

151

Sundry machines have been contrived both for grinding the subject and pressing out the oil, in the way of business. To facilitate the expression, it is usual to warm either the plates of the press, or the subject itself after the grinding, by keeping it stirring in a proper vessel over the fire; the oil, liquefied by the heat separates more freely and more plentifully. When the oil is designed for medicinal purposes, this practice is not to be allowed; for heat, especially if its degree be sufficient to be of any considerable advantage for promoting the separation, renders the oil less soft and palatable, impresses a disagreeable flavour, and increases its disposition to grow rancid: hence the colleges both of London and Edinburgh expressly require the operation to be performed without heat.

Nor are the oils to be kept in a warm place after their expression. Exposed for a few days to heat no greater than that of the human body, they lose their emollient quality, and become highly rancid and acrimonious. Too much care cannot be taken for preventing any tendency to this acrid irritating state in medicines, so often used for abating immoderate irritation.

So much are these oils disposed to this injurious alteration, that they frequently contract an acrimony and rancidity while contained in the original subjects. Hence great care is requisite in the choice of the unctuous seeds and kernels, which are often met with very rancid; almonds are particularly liable to inconveniences of this kind.

Expressed oils are prepared for mechanic uses from sundry different subjects, as nuts, poppy-seed, hemp-seed, rape-seed, and others. Those directed for medicinal purposes in the London and Edinburgh pharmacopœias are the following:

Oil of almonds. L. E.

Pound fresh almonds, either sweet or bitter, in a mortar, then press out the oil in a cold press.

152

Prepara-
tions and
Composi-
tions.

In the same manner is to be expressed oil of lintseed and oil of mustard-seed.

The oil of almonds is prepared from the sweet and bitter almonds indifferently, the oils obtained from both sorts being exactly the same. Nor are the differences of the other oils very considerable, the discriminating qualities of the subjects not residing in the oils that are thus obtained by expression. The oil of lintseed acquires indeed some peculiarities from containing a portion of vegetable mucilage; but the oil of mustard-seed is as soft, insipid, and void of pungency, as that of sweet almonds, the pungency of the mustard remaining entire in the cake left after the expression. The several oils differ in some of their properties from each other; but in medicinal qualities they appear to be all nearly alike, and agree in one common emollient virtue. They soften and relax the solids, and obtund acrimonious humours; and thus become serviceable internally in pains, inflammations, heat of urine, hoarseness, tickling coughs, &c. in glysters, for lubricating the intestines, and promoting the ejection of indurated feces; and in external applications, for tension and rigidity of particular parts. Their common dose is half an ounce; in some cases they are given to the quantity of three or four ounces. The most commodious forms for their exhibition we shall see hereafter in the chapter of Emulsions.

Caster oil. L.

153

This oil is directed by the London college to be prepared in the same manner as that of almonds, the seeds or nuts being taken from the hulks before putting them into the mortar. Palma Christi, or castor oil, (See *OLEUM Palmae Christi*, and *RICINUS*), is a gentle and useful purgative: it generally produces its effects without griping, and may be given with safety where acid purgatives are improper. With adults, from half an ounce to an ounce is generally requisite for a dose. This article, however, is very seldom prepared by our apothecaries, being in general imported under the form of oil from the West Indies: hence the Edinburgh college have not mentioned it among their preparations, but merely given it a place in their list of the materia medica. But when our apothecaries prepare it for themselves, they are more certain of obtaining a pure oil, and one too obtained without the aid of heat, which is often employed, and gives a much inferior oil. It is therefore with propriety that the London college have given directions for the preparation of it by the apothecary himself. But even the London college have not thought it necessary to give directions for the preparation of the expressed oils, which, as well as the *oleum ricini*, are also introduced into the list of the materia medica by the Edinburgh college.

Expressed oil of bay berries.

mace,
olives,
palm.

154

These also are principally considered as possessing only an emollient virtue; but as far as they have been supposed to exert any peculiar qualities, these we have

VOL. XIV.

had occasion to mention in other parts of the work, when treating of the articles from which they are obtained. See *OLIA*, *MACI*, &c.

Oil of chocolate nuts. Succ.

Express the oil from the nuts slightly toasted, and freed from their coverings.

In this oil we have the nutritious part of chocolate, free from those aromatics with which it is united in the state in which it is kept in our shops. And although under the form of chocolate it fits perhaps more easily on the stomach than in most other forms; yet where, from any particular circumstance, aromatics are contraindicated, the oil in its pure state gives us an opportunity of employing in different ways this mild nutritious article.

Oil of hyoscyamus. Succ.

This oil is directed to be obtained by expression from the seeds of the hyoscyamus, in the same manner as that of almonds.

Of the narcotic powers of the hyoscyamus some observations have already been offered. This oil, although an expressed one, is said to retain these virtues; and accordingly it has entered the composition of some anodyne ointments and plasters. We are, however, inclined to think, that when the sedative power of hyoscyamus is wanted under the form of oil, it may be best obtained from impregnating olive oil by the leaves of the plant.

Egg oil. Succ.

Take any quantity of fresh eggs, boil them till they be quite hard; then take out the yolks, break them in pieces, and roast them gently in a frying-pan till they feel greasy when pressed between the fingers; put them while warm into a hair bag, and express the oil.

The yolk of the egg is well known to be a mild nutritious substance: but notwithstanding the many virtues at one time attributed to it, of being purgative and styptic, as externally applied; and of being useful in stomach complaints, dysentery, and different affections of the alimentary canal, when taken internally;—it is much to be doubted whether it be in any other way useful in medicine than as an article of diet; and we are very uncertain whether any particular purpose in medicine will be answered by this expressed oil: but as it holds a place in most of the foreign pharmacopœias of modern date, it may justly be considered as deserving some attention.

Notwithstanding the justice of the observation respecting the great similarity of expressed oils in general, yet there can be no doubt that in some instances they obtain a peculiar impregnation. This manifestly appears in the *oleum ricini*, *oleum nucis mollioris*, and some of the others mentioned above. Indeed oils expressed from aromatic substances in general retain some admixture of the essential oil of the subject from which they are expressed. Nor is this surprising, when we consider that in some cases the essential oil exists in a separate state even in the growing plant.

The rinds of the several varieties of oranges, lemons, and citrons, yield by a kind of expression their essential

S f oils

oils almost pure, and nearly similar to those which are obtained from them by distillation. The essential oils, in which the fragrance and aromatic warmth of these fruits reside, are contained in numerous little vesicles, which may be distinguished by the naked eye, spread, all over the surface of the peel. If the rind be cut in slices, and the slices separately doubled or bent in different parts, and squeezed between the fingers, the vesicles burst at the bending, and discharge the oil in a number of fine slender jets. A glass plate being set upright in a glass or porcelain vessel, and the slices squeezed against the plates, the little jets unite into drops upon the plate, and trickle down into the vessel beneath. But though this process affords the true native oil in the same state wherein it existed in the subject, unaltered by fire or other agents, it is not practicable to advantage unless where the fruit is very plentiful, as only a small part of the oil it contains can thus be extracted or collected.

The oil is more perfectly separated by rubbing the rind upon a lump of sugar. The sugar, by the inequality of its surface, produces the effect of a rasp in tearing open the oily vesicles, and in proportion as the vesicles are opened the sugar imbibes the oil. When the outward part of the lump is sufficiently moistened, it is scraped off, and the operation continued on the new surface. The oil thus combined with the sugar is fit for most of the uses to which it is applied in a fluid state. Indeed the pure essential oils obtained by distillation are often purposely mixed with sugar to render their use the more commodious.

CHAP. VI. *Essential oils.*

158

ESSENTIAL oils are obtained only from odoriferous substances; but not equally from all of this class, nor in quantity proportional to their degree of odour. Some which, if we were to reason from analogy, should seem very well fitted for this process, yield extremely little oil, and others none at all. Roses and carnation flowers, whose strong and lasting smell promises abundance, are found upon experiment to contain but a small quantity; the violet and jessamine flower, which perfume the air with their odour, lose their smell upon the gentlest coction, and do not afford the least perceptible mark of oil on being distilled unless immense quantities are submitted to the operation at once; while saffron, whose disagreeable scent extends to no great distance, gives out the largest proportion of oil of almost any vegetable known.

Nor are the same plants equally fit for this operation when produced in different soils or seasons, or at different times of their growth. Some yield more oil if gathered when the flowers begin to fall off than at any other time. Of this we have examples in lavender and rue; others, as sage, afford the largest quantity when young, before they have sent forth any flowers; and others, as thyme, when the flowers have just appeared. All fragrant herbs yield a larger proportion of oil when produced in dry soils and warm summers than in opposite circumstances. On the other hand, some of the disagreeable strong-scented ones, as wormwood, are said to contain most in rainy seasons and when growing in moist rich grounds.

Several of the chemists have been of opinion, that

Preparations and Compositions.

herbs and flowers, moderately dried, yield a greater quantity of essential oil than if they were distilled when fresh. It is supposed, that the oil being already blended in fresh plants, with a watery fluid, great part of it remains diffused through the water after the distillation, divided into particles too minute to unite and be collected; whereas in drying, the oily parts, on the exhalation of the moisture which kept them divided and dispersed, run together into globules, which have little disposition to mingle with watery fluids, and easily separate from the water employed in the distillation.

This theory, however, does not appear to be quite satisfactory; for though the oil be collected in the subject into distinct globules, it does not rise in that form, but is resolved into vapour, and blended and coagitated by the heat with the vapour of the water; and if the oil in a dry plant was less disposed to unite with aqueous fluids than in a fresh one, the dry ought to yield a weaker infusion than the fresh; the contrary of which is generally found to obtain. As the oil of the dry plant is most perfectly extracted and kept dissolved by the water before the distillation, it is difficult to conceive any reason why it should have a greater tendency to separate from the water afterwards.

The opinion of dry plants yielding most oil seems to have arisen from an observation of Hoffman, who has probably been misunderstood: "A pound (he says) of dry spike flowers yields an ounce of oil, but if they were distilled fresh they would scarcely yield above half an ounce; and the case is the same in balm, sage, &c. The reason is, that in drying the watery humidity exhales; and as from two pounds of a fresh plant we do not obtain above one pound of dry, and little of the subtle oil evaporates in the drying, it follows, that more oil ought to be afforded by the dry than by the fresh." The meaning of which seems to be no more than this, that if two pounds of a fresh plant are by drying reduced to one without any loss of the oil, then the one pound dry ought to be equivalent to the two fresh. A late writer quotes an experiment of Neumann, which appears to be misunderstood in the same manner; for Neumann, in the place referred to, says only that dry wormwood is found to yield much more oil than an *equal weight* of the fresh plant. Trials are yet wanting in which fresh and dry plants have been brought to a fair comparison, by dividing a quantity of the subject into two equal weights, and distilling one while fresh, and the other after it has been carefully and moderately dried.

But whatever may be the effect of moderate exsiccation, it is certain, that if the drying be long continued, the produce of oil will be diminished, its colour altered, and its smell impaired.

With regard to the proportion of water to be employed, if whole plants moderately dried are used, or the shavings of wood, as much of either may be put into the vessel as, lightly pressed, will occupy half its cavity: and as much water may be added as will fill two-thirds of it. The water and ingredients altogether should never take up more than three-fourths of the still; there should be liquor enough to prevent any danger of an empyreuma, but not so much as to be too apt to boil over into the receiver.

The

Prepara-
tions and
Composi-
tions.

The maceration should be continued so long that the water may fully penetrate the parts of the subject. To promote this effect, woods should be thinly shaved across the grain or sawn, roots cut transversely into thin slices, barks reduced into coarse powder, and seeds slightly bruised. Very compact and tenacious substances require the maceration to be continued a week or two, or longer; for those of a softer and looser texture, two or three days are sufficient; while some tender herbs and flowers not only stand in no need of maceration, but are even injured by it.

Whether the addition of sea-salt, which some have recommended, be of any real service, is much to be doubted. The uses generally assigned to it are, to penetrate and unlock the texture of the subject more effectually than simple water could do, and to prevent the fermentation or putrefaction which the matter is apt to run into during the length of time for which the maceration is often continued. But sea-salt seems rather to harden and condense, than to soften and resolve, both vegetable and animal subjects; and if it prevents putrefaction, it must, on that very account, be injurious rather than of service. The resolution here aimed at approaches near to a beginning putrefaction; and saline substances, by retarding this, prolong the maceration far beyond the time that would otherwise be necessary. It is in the power of the operator, when he perceives the process coming near this pitch, to put a stop to it at pleasure, by proceeding immediately to distillation. By this means the whole affair will be finished in a very little time, with at least equal advantage in every other respect; provided the manual operations of pounding, rasping, and the like, which are equally necessary in either case, be minutely complied with.

Bodies of a very viscous and compact texture were directed, in the Edinburgh pharmacopœia, to be fermented for some days with a little yeast. Half their quantity of water is sufficient for performing the fermentation: as much more as is necessary is to be added afterwards before the distillation. This process undoubtedly promotes the resolution of the subject, and the extrication of the oil. It rarely happens, however, that assistances of this kind are needful. Particular care must be had not to continue the fermentation too long; or to give a bad flavour to the oil by an ill-chosen ferment, or using too large a quantity of any.

Some chemists pretend, that by the addition of salts and acid spirits they have been enabled to gain more oil from certain vegetable matters than could possibly be got from them without such assistance. Experiments made on purpose to settle this point seem to prove the contrary: this at least is constantly found to be true, that where there is any reason to think the produce greater than usual, the quality of the oil is proportionally injured. The quantity of true essential oil in vegetables can by no means be increased; and what is really contained in them may be easily separated without any addition of this kind. All that saline matters can do in this respect is to make the water susceptible of a greater degree of heat than it can sustain by itself, and thus enable it to carry up a gross unctuous matter not volatile enough to rise with pure water: this gross matter, mingling with the pure oil, increases the quantity, but at the same time

must necessarily debase its quality. And indeed, when water alone is used, the oil which comes over about the end of the operation is remarkably less fragrant, and of a thicker consistence, than that which rises at the beginning: distilled a second time, with a gentle heat, it leaves a large quantity of gross almost insipid resinous matter behind.

The choice of proper instruments is of great consequence for the performance of this process to a advantage. There are some oils which pass freely over the swan neck of the head of the common still; others, less volatile, cannot easily be made to rise so high. For obtaining these last, we would recommend a large low head, having a rim or hollow canal round it. In this canal the oil is detained on its first ascent, and thence conveyed at once into the receiver, the advantages of which are sufficiently obvious.

With regard to the fire, the operator ought to be expeditious in rising it at first, and to keep it up, during the whole process, of such a degree that the oil may freely distil; otherwise the oil will be exposed to an unnecessary heat; a circumstance which ought as much as possible to be avoided. The communication to all these oils a disagreeable impregnation, as is evident from their being much less grateful when newly distilled, than after they have stood for some time in a cool place; the longer the heat is continued, the more alteration it must produce in them.

The greater number of oils require for their distillation the heat of water strongly boiling; but there are many also which rise with a heat considerably less; such as those of lemon and citron-peel, of the flowers of lavender and rosemary, and of almost all the more odoriferous kinds of flowers. We have already observed, that these flowers have their fragrance much injured, or even destroyed, by beating or bruising them; is impaired also by the immersion in water in the present process, and the more so in proportion to the continuance of the immersion and the heat: hence oils, distilled in the common manner, prove much less agreeable in smell than the subjects themselves. For the distillation of substances of this class another method has been contrived; instead of being immersed in water, they are exposed only to its vapour. A proper quantity of water being put to the bottom of the still, the odoriferous herbs or flowers are laid lightly in a basket, of such a size that it may enter into the still, and rest against its sides, just above the water. The head being then fitted on, and the water made to boil, the steam, percolating through the subject, imbibes the oil, without impairing its fragrance, and carries it over to the receiver. Oils thus obtained possess the odour of the subject in an exquisite degree, and have nothing of the disagreeable scent perceivable in those distilled by boiling them in water in the common manner.

It may be proper to observe, that those oils which rise with a less heat than that of boiling water, are generally called, by the chemical and pharmaceutical writers, *light oils*; and those which require the heat of water strongly boiling, are called *ponderous*. We have avoided these expressions, as they might be thought to relate to the comparative *gravities* of the oils; with which the volatility or fixedness have no connection. Olive oil is lighter than most of the es-

essential oils; but the heat requisite to make it distil, exceeds that in which the heaviest essential oil distils, considerably more than the heat of boiling water exceeds that of ice.

The water employed in the distillation of essential oils always imbibes some portion of the oil; as is evident from the smell, taste, and colour, which it acquires. It cannot, however, retain above a certain quantity; and therefore, such as has been already used and consequently saturated with oil, may be advantageously employed, instead of common water, in a second, third, or any future distillation of the same subject.

Some late chemical writers recommend, not the water which comes over, but that which remains in the still, to be used a second time. This can be of no service; as consisting only of such parts of the vegetable as are incapable of arising in distillation, and which serve only to impede the action of the water as a menstruum, and to endanger an empyreuma.

After the distillation of one oil particular care should be taken to cleanse the worm before it be employed in the distillation of a different plant. Some oils, those of wormwood and aniseeds for instance, adhere to it so tenaciously, as not to be melted out by heat, or washed off by water; the best way of cleansing the worm from these, is to run a little spirit of wine through it.

Essential oils, after they are distilled, should be suffered to stand for some days, in vessels loosely covered with paper, till they have lost their disagreeable fiery odour, and become limpid: then put them up in small bottles, which are to be kept quite full, closely stopp'd, in a cool place: with these cautions, they will retain their virtues in perfection for many years.

When carefully kept, they in time gradually lose their flavour, and become gross and thick. Some endeavour to recover them after they have undergone this change, by gauding them with about twice their weight of common salt, then adding a large proportion of water, and distilling them afresh; the purer part rises thin and limpid, possessing a great degree of the pristine smell and taste of the oil, though inferior in both respects to the original oil. This rectification, as it is called, succeeds equally without the salt: the oils, when thus altered, are nearly in the same state with the turpentine, and other thick-ended oily juices, which readily yield their purer oil in distillation with water alone.

When essential oils have entirely lost their smell, some recommend adding them in the distillation of a fresh quantity of the oil of the same plant; by which means they are said to satiate themselves anew with the odorous matter, and become entirely renovated. This practice, however, ought doubtless to be disapproved, as being no other than a specious sophistication; for it can do no more than divide, between the old and the new, the active matter which belongs to the new alone.

Essential oils medicinally considered, agree in the general qualities of pungency and heat; in particular virtues, they differ as much as the subject from which they are obtained, the oil being the direct principle

in which the virtues, or at least a considerable part of the virtues, of the several subjects reside. Thus the carminative virtue of the warm seeds, the diuretic of juniper-berries, the emmenagogue of savin, the nerve of rosemary, the stomachic of mint, the antifebrutic of scurvy grass, the cordial of aromatics, &c. are supposed to be concentrated in their oil.

There is another remarkable difference in essential oils, the foundation of which is less obvious, viz. the degree of their pungency and heat. These are by no means in proportion, as might be expected, to those of the subject they were drawn from. The oil of cinnamon, for instance, is very pungent and fiery; in its undiluted state it is almost caustic; whereas cloves, a spice which in substance is far more pungent than the other, yields an oil which is far less so. This difference seems to depend partly on the quantity of oil afforded, cinnamon yielding much less than cloves, and consequently having its active matter concentrated into a smaller volume; partly on a difference in the nature of the active parts themselves; for though essential oils contain always the specific odour and flavour of their subjects, whether grateful or ungrateful, they do not always contain the whole pungency; this resides frequently in a more fixed resinous matter, and does not rise with the oil. After the distillation of cloves, pepper, and some other spices, a part of their pungency is found to remain behind; a simple tincture of them in rectified spirit of wine is even more pungent than their pure essential oils.

The more grateful oils are frequently used for reconciling to the stomach medicines of themselves disgusting. It has been customary to employ them as correctors for the resinous purgatives; an use which they do not seem to be well adapted to. All the service they can here be of, is, to make the resin sit more easily at first on the stomach; far from abating the irritating quality on which the virulence of its operation depends, these pungent oils superadd a fresh stimulus.

Essential oils are never given alone, on account of their extreme heat and pungency; which in some is so great, that a single drop let fall upon the tongue produces a gangrenous eschar. They are readily imbibed by pure dry sugar, and in this form may be conveniently exhibited. Ground with eight or ten times their weight of sugar, they become soluble in aqueous liquors, and thus may be diluted to any assigned degree. Mucilages also render them miscible with water into an uniform milky liquor. They dissolve likewise in spirit of wine; the more fragrant in an equal weight, and almost all of them in less than four times their own quantity; these solutions may be either taken on sugar, or mixed with syrups, or the like: on mixing them with water, the liquor grows milky, and the oil separates.

The more pungent oils are employed externally against paralytic complaints, numbness, pains, and aches, cold tumors, and in other cases where particular parts require to be heated or stimulated. The tooth-ach is sometimes relieved by a drop of these almost caustic oils, received on cotton, and cautiously introduced into the hollow-tooth.

Prepara-
tions and
Composi-
tions.*Essential oil of anise,* L.

caraway,
lavender,
peppermint,
spearmint,
origanum,
pennyroyal,
rosemary,
juniper berry,
Jassifras root.

159 Let these oils be drawn off by distillation, from an alembic with a large refrigerator; but, to prevent an empyreuma, water must be added to the ingredient; in which they must be macerated before distillation.

The water which comes over with the oil in distillation is to be kept for use.

Essential oils. E.

Of the herbs of garden mint,
Of peppermint,
Of fawn,
Of the tops of rosemary,
Of the flowering spikes of lavender,
Of aniseeds,
Of juniper-berries,
Of jassifras root,
Of Jamaica pepper.

160 These are prepared almost in the same manner as the simple distilled waters, excepting that for procuring the oil a somewhat less quantity of water is to be used. Seeds and woody matters are first to be bruised or rasped. The oil rises with the water; and as it is lighter or heavier, swims on the surface, or sinks to the bottom, from which it is afterwards to be separated.

It is, however, to be remarked, that in preparing these distilled waters and oils, so many varieties must necessarily take place from the goodness of the subject itself, its texture, the time of the year, and such like circumstances, that a certain and general rule, which should strictly apply to each example, can scarcely be laid down: wherefore we have only explained the general method, leaving many things to be varied by the judgment of the operator.

To the directions for preparing these essential oils given by the London and Edinburgh colleges, we shall here next subjoin a few remarks on their medical properties.

Essential oil of aniseeds. L. E.

161 This oil possesses the taste and smell of the aniseeds in perfection. It is one of the mildest of the distilled oils; 15 or 20 drops may be taken at a time without danger, though common practice rarely goes so far as half this number. Its smell is extremely durable and diffusible; milk drawn from the breast after taking it, is found impregnated with its odour; and possibly this may be, in part, the foundation of the pectoral virtues usually ascribed to it; in flatulencies and colics, it is said by some to be less effectual than the seeds themselves.

It is remarkable of this oil, that it congeals, even when the air is not sensibly cold, into a butyraceous consistence: and hence, in the distillation of it, the

operator ought not to be over-solicitous in keeping the water in the refrigerator too cool: it behoves him rather to let it grow somewhat hot, particularly towards the end of the process; otherwise the oil congealing may so stop up the worm, as to endanger blowing off the head of the still, or at least a considerable quantity of oil will remain in it.

Essential oil of caraway seeds. L.

The flavour of this exactly resembles that of the caraway itself. It is a very hot and pungent oil: a single drop is a moderate dose, and five or six is a very large one. It is not unfrequently used as a carminative; and supposed by some to be peculiarly serviceable for promoting urine, to which it communicates some degree of its smell.

Essential oil of lavender flowers. L. E.

This oil, when in perfection, is very limpid, of a pleasant yellowish colour, extremely fragrant, possessing in an eminent degree the peculiar smell generally admired in the flowers. It is a medicine of great use, both externally and internally, in paralytic and lethargic complaints, rheumatic pains, and debilities of the nervous system. The dose is from one drop to five or six.

Lavender flowers yield the most fragrant oil, and considerably the largest quantity of it, when they are ready to fall off spontaneously, and the leaves begin to show themselves: the seeds give out extremely little the flowers may be separated from the rest of the plant, by drying it a little, and then gently beating it: they should be immediately committed to distillation, and the process conducted with a well-regulated gentle heat; too great heat would not only change the colour of the oil, but likewise make a disagreeable alteration in its smell.

Essential oil of the leaves of peppermint. L. E.

This possesses the smell, taste, and virtues of the peppermint in perfection; the colour is a pale greenish yellow. It is a medicine of great pungency and subtlety; and diffuses, almost as soon as taken, a glowing warmth through the whole system. In colics, accompanied with great coldness, and in some hysterical complaints, it is of excellent service. A drop or two are in general a sufficient dose.

Essential oil of the leaves of common mint. L. E.

This oil smells and tastes strongly of the mint, but is in both respects somewhat less agreeable than the herb itself. It is an useful stomachic medicine; and not unfrequently exhibited in want of appetite, weakness of stomach, retching to vomit, and other disorders, when not accompanied with heat or inflammation: two or three drops, or more are given for a dose. It is likewise employed externally for the same purposes; and is an useful ingredient in the stomachic plaster of the shops.

Essential oil of the leaves of origanum. L.

This oil has a very pungent acriminous taste, and a penetrating smell. It has been chiefly employed externally as an errhine and for easing pains of the teeth,

Essential

Essential oil of the leaves of pennyroyal. L.*Essential oil of Jamaica pepper.* E.

This oil, in smell and taste, resembles the original plant; the virtues of which it likewise possesses. It is given in hysterical cases, from one to four or five drops.

This is a very elegant oil, and may be used as a succedaneum to those of some of the dearer spices. It is of a fine pale colour; in flavour more agreeable than the oil of cloves, and not far short of that of nutmegs. It sinks in water, like the oils of some of the eastern spices.

Essential oil of rosemary. L. E.*Oil of fossil tar.* L.

The oil of rosemary is drawn from the plant in flower. When in perfection, it is very light and thin, pale, and almost colourless; of great fragrant, though not quite so agreeable as the rosemary itself. It is recommended, in the dose of a few drops, in nervous and hysterical complaints. Boerhaave holds it in great esteem against epilepsies and suppressions of the uterine purgations occasioned by weakness and inactivity.

Distil fossil tar, the *bitumen petroleum*, in a sand heat.

The oil obtained from this tar will be more or less thin according to the continuance of the distillation; and by its continuance the tar will at last be reduced to a black coal and then the oil will be pretty deep in colour though perfectly fluid. This oil has a property similar to that of the tincture of nephritic wood in water, appearing blue when looked upon, but of an orange colour when held between the eye and the light. By long keeping it loses this property. It is less disagreeable than some of the other empyreumatic oils which had formerly a place in our pharmacopœia, such as the *oleum lateritium*, though very acrid and stimulating.

Essential oil of juniper-berries. L. E.*Oil of turpentine.* L.

This oil is a very warm and pungent one; of a strong flavour, not unlike that of the berries. In the dose of a drop or two, it proves a serviceable carminative and stomachic; in one of six, eight, or more, a stimulating, detergent, diuretic, and emmenagogue; it seems to have somewhat of the nature of the turpentine, or their distilled oil; like which it communicates a violent smell to the urine.

Take of common turpentine five pounds; water four pints. Distil the turpentine with the water from an alembic of copper. After the distillation of the oil, what remains is yellow resin.

The oil of these berries resides partly in vesicles spread through the substance of the fruit, and partly in little cells contained in the seeds: when the berry is dry, and the oil hardened into a resinous substance, it becomes visible, on breaking the seeds, in form of little transparent drops. In order therefore to obtain this oil to advantage, we ought previous to the distillation, to bruise the berry thoroughly, so as to break the seeds, and entirely lay open the oily receptacles.

Essential oil of sassafras. L. E.*Rectified oil of turpentine.* L.

This is the most ponderous of all the known essential oils, but rises in distillation with sufficient ease: it appears limpid as water, has a moderately pungent taste, a very fragrant smell, exactly resembling that of the sassafras. It stands greatly commended as a sudorific, and for purifying the blood and juices; it is likewise supposed to be of service in humoral asthma and coughs. The dose is from one drop to eight or ten; though Geoffroy goes as far as twenty.

Take of oil of turpentine one pound; water four pints. Distil.

The process here proposed for rectifying this oil, is not only tedious but accompanied with danger. For unless the luting be very close, some of the vapour will be apt to get through; and if this catch fire, it will infallibly burst the vessels. This rectified oil, which in many pharmacopœias is styled æthereal, does not considerably differ in specific gravity, smell, taste, or medical qualities, from the former.

The decoction remaining after the distillation of the oil, affords by inspissation a useful extract, of a mild, bitterish, subastriquent taste. Hoffman says, he has given it with great benefit, in doses of a scruple, as a corroborant in cachectic cases, in the decline of intermitting fevers, and for abating hypochondriacal spasms.

Essential oil of savin leaves. L. E.*Animal oil.* L.

Savin is one of the plants which, in former editions of the Edinburgh pharmacopœia, were directed to be lightly fermented before the distillation: this, however, is not very necessary; for savin yields, without fermentation, and even without any such maceration, a very large quantity of oil. The oil of savin is a celebrated uterine and emmenagogue: in cold phlegmatic habits, it is undoubtedly a medicine of great service, though not capable of performing what it has been often represented to do. The dose is, two or three drops, or more.

Take of oil of hawthorn one pound. Distil three times.

Rectified oil of horns, or animal oil. E.

Take of empyreumatic oil, newly distilled from the horns of animals, as much as you will. Distil with a gentle heat, in a matrafs furnished with a head, as long as a thin colourless oil comes over, which is to be freed of alkaline salt and spirit by means of water.

Preparations and Compositions,

Preparations and Compositions.

water. That this oil may remain limpid and good, it ought to be put up in small phials, completely filled and inverted, having previously put into each phial a few drops of water, that on inverting it the water may interpose itself between the oil and the mouth of the phial.

The quantity of oil employed in this process should be considerable: for it leaves so much black matter behind in the several distillations, that it is reduced at last to a small portion of its original quantity. It is said, that the product is rendered more limpid by mixing the oil with quicklime into a soft paste; the lime keeping down more of the gross matter than would remain without such an addition. The quicklime may here also perhaps act by extracting fixed air; to the absorption of which we are disposed to refer in some measure the spoiling of the oil on exposure to the atmosphere.

The oil was first introduced by Dippelius, whose name it has since generally borne.

Animal oils thus rectified, are thin and limpid, of a subtle, penetrating, not disagreeable smell and taste. They are strongly recommended as anodynes and antispasmodics, in doses from 15 to 30 drops. Hoffman reports, that they procure a calm and sweet sleep which continue often for 20 hours, without being followed by any languor or debility, but rather leaving the patient more alert and cheerful than before; that they procure likewise a gentle sweat, without increasing the heat of the blood: that given to 20 drops or more on an empty stomach, six hours before the accession of an intermittent fever, they frequently remove the disorder; and that they are likewise a very generous remedy in inveterate and chronic epilepsies and in convulsive motions, especially if given before the usual time of the attack, and preceded by proper evacuations.

The empyreumatic oils of vegetables, rectified in the same manner by repeated distillations, suffer a like change with the animal losing their dark colour and offensive smell, and becoming limpid, penetrating, and agreeable: in this state they are supposed, like the animal oil, to be anodyne, antispasmodic, and diaphoretic or sudorific. It is observable, that all the empyreumatic oils dissolve in spirit of wine, and that the oftener they are rectified or redistilled, they dissolve the more readily; a circumstance in which they differ remarkably from essential oils, which, by repeated distillations, become more and more difficult of solution.

How far these preparations really possess the virtues that have been ascribed to them, has not yet been sufficiently determined by experience; the tediousness and trouble of the rectification having prevented their coming into general use, or being often made. They are liable also to a more material inconvenience, in regard to their medicinal use, precariousness in their quality; for how perfectly soever they be rectified, they gradually lose in keeping the qualities they had received from that process, and return more and more towards their original fetid state.

Oil of salt of amber. E.

glass retort, of which the mixture may fill one half; then adapt a large receiver, and distil in a sand furnace, with a fire gradually increased. At first a spirit will come over, with some yellow oil; then more yellow oil, along with a little salt; and on raising the heat, more of the salt, with a reddish and black coloured oil. When the distillation is finished, empty the liquor out of the receiver; and having collected together the salt which adheres to the sides, dry it by gentle pressure between the folds of blotting paper; then purify it by solution in warm water and by crystallization.

Rectified oil of amber.

Distil the oil in a glass retort with six times its quantity of water till two thirds of the water have passed into the receiver; then separate the rectified oil from the water, and keep it for use in close shut vessels. *E.*

Take of oil of amber one pound. Distil three times *L.*

The London college introduce their directions for the preparation of the sal and oleum succini at an after part of their work, under the head of *succin.* Here we may only observe, that they direct it to be prepared from the amber alone, without the intervention of sand. But this makes no essential difference in the article when prepared.

The Edinburgh college have rejected what was formerly called the spirit, as being nothing else than the watery parts, fraught with the inert impurities of the bitumen and a very small portion of the salt. In the distillation of amber, the fire must for some time be continued gentle, scarce exceeding the degree at which water boils, till the aqueous phlegm and thin oil have arisen; after which it is to be slowly increased. If the fire were urged hastily, the amber would swell up, and rise in its whole substance into the receiver, without undergoing the required decomposition or separation of its parts. When sand or similar intermedia are mixed with it, it is less subject to this rarefaction, and the fire may be raised somewhat more expeditiously; though this little advantage is perhaps more than counterbalanced by the room which the sand takes up in the retort.

Our chemists generally leave the receiver unluted, that it may be occasionally removed as the salt rises and concretes in the neck of the retort; from whence it is every now and then scraped out to prevent the oil from carrying it down into the receiver. When a gross thick oil begins to arise, and no more salt appears, the distillation is stopt, though it might perhaps be continued longer to advantage.

Mr Pott informs us (in a curious dissertation on the salt of amber, published in the ninth volume of the Memoirs of the Academy of Sciences of Berlin), that the Prussian workmen, who prepare large quantities of this salt for exportation, from cuttings and small pieces of amber, perform the distillation without any intermedium, and in an open fire: that sweeping out the salt from the neck of the retort being found too troublesome, they suffer the oil to carry it down into the receiver, and afterwards separate it by means of bibulous paper, which imbibes the oil, and leaves the salt dry; which paper is afterwards squeezed and distilled: that they continue the distillation till all that can be forced.

Take equal parts of amber reduced to a powder and of pure sand. Mix them and put them into a

Preparations and Compositions.

forced over has arisen, taking care only to catch the last thick oil in a separate receiver; and that from this they extract a considerable quantity of salt, by shaking it in a strong vessel with three or four fresh portions of hot water, and evaporating and crystallizing the filtered waters.

The spirit of amber, so called, is no more than a solution of a small proportion of the salt in phlegm or water; and therefore is very properly employed for dissolving the salt in order to its crystallization.

The salt, freed from as much of the oil as spongy paper will imbibe, remains so much as to appear of a dark brown colour. Mr Pett says, the method he has found to succeed best, and with least loss, is to dissolve the salt in hot water, and put into the paper, through which the solution is to be filtered, a little cotton slightly moistened with oil of amber: this, he says, detains a good deal of the oil of the salt, and the solution passes through the more pure. The liquor being evaporated with a very gentle fire, as that of a water-bath, and set to float, the first crystals prove transparent, with a slight yellowish tinge; but these which follow, are brown, oily, and bitter, and are therefore to be further depurated in the same manner. The whole quantity of crystals amounts to about one thirtieth of the weight of the crude amber employed. By sublimation from sea salt, as directed in former editions of the Edinburgh pharmacopœia, the salt is thought to be more perfectly and more expeditiously purified: Mr Pott objects to sublimation, that a part of the salt is decomposed by it, a coaly matter being left behind, even though the salt was previously purified by crystallization: it may be presumed, however, that this coal proceeds rather from the burning of some remains of the oily matter, than from the decomposition of any part of the true salt.

Pure salt of amber has a penetrating, subastrigent, acid, taste. It dissolves both in water and in rectified spirit; though not readily in either, and scarcely at all in the latter without the assistance of heat: of cold water in summer, it requires for its solution about twenty times its own weight; of boiling water only about twice its weight. Exposed in a glass vessel, to a heat little greater than that of boiling water, it first melts, then rises in a white fume, and concretes again in the upper part of the glass into fine white flakes, leaving, unless it was perfectly pure, a little coaly matter behind. It effervesces with alkalis both fixed and volatile, and forms with them neutral compounds much resembling those composed of the same alkalis and vegetable acids. Mixed with acid liquors, it makes no sensible commotion. Ground with fixed alkaline salts it does not exhale any urinous odour. By these characters, it is conceived this salt may be readily distinguished from all the other matters that have been mixed with or vended for it. With regard to its virtue, it is accounted aperient, diuretic, and, on account of its retaining some portion of the oil, antihysterical: Boerhaave gives it the character of *diureticorum et antihystericorum princeps*. Its great price, however, has prevented its coming much into use; and perhaps its real virtues are not equal to the opinion generally entertained of them.

The rectified oil has a strong bituminous smell, and a pungent acrid taste. Given in a dose of ten or

twelve drops, it heats, stimulates, and promotes the fluid secretions: It is chiefly celebrated in hysterical disorders, and in deficiencies of the uterine purgations. Sometimes it is used externally, in liniments for weak or paralytic limbs and rheumatic pains. This oil differs from all those of the vegetable kingdom, and agrees with the mineral petrolea, in not being soluble either in its rectified or unrectified state, by spirit of wine, fixed alkaline lixivia, or volatile alkaline spirits; the oil, after long digestion or agitation, separating as freely as common oil does from water.

Oil of wine. L.

Take alcohol, vitriolic acid, of each one pint. Mix them by degrees, and distil; taking care that no black foam passes into the receiver. Separate the oily part of the distilled liquor from the volatile vitriolic acid. To the oily part add as much water of pure kali as is sufficient to take away the sulphureous smell: then distil the ether with a gentle heat. The oil of wine remains in the retort, swimming on the watery liquor, from which it is to be separated.

Some caution is requisite in mixing the two liquors, that the consequent heat and ebullition, which would not only dissipate a part of the mixture, but hazard the breaking of the vessel and the hurt of the operator, may be avoided. The securest way is to add the vitriolic acid to the spirit of wine by a little at a time, waiting till the first addition be incorporated before another quantity be put in. By this, the ensuing heat is inconsiderable, and the mixture is effected without inconvenience.

Essential oil of wormwood. Ross.

Let the fresh leaves of wormwood slightly dried be macerated with a sufficient quantity of water, and then subject to distillation; and let the oil which comes over be separated from the water which accompanies it.

This is one of the more ungrateful oils: it smells strongly of the wormwood, and contains its particular nauseous taste, but has little or nothing of its bitterness, this remaining entire in the decoction left after the distillation: its colour, when drawn from the fresh herb is dark green; from the dry, a brownish yellow. This oil is recommended by Hoffman as a mild anodyne in spasmodic contractions; for this purpose, he directs a dram of it to be dissolved in an ounce of rectified spirit of wine, and seven or eight drops of the mixture taken for a dose in any convenient vehicle. Boerhaave greatly commends, in tertian fevers, a medicated liquor composed of about seven grains of this oil ground first with a dram of sugar, then with two drams of the salt of wormwood, and afterwards dissolved in six ounces of the distilled water of the same plant: two hours before the fit is expected, the patient is to bathe his feet and legs in warm water, and then to drink two ounces of the liquor every quarter of an hour till the two hours are expired: by this means, he says, all cases of this kind are generally cured with ease and safety, provided there be no schirrosity or suppuration. The oil of wormwood is employed chiefly as a vermifuge; and for this purpose is sometimes applied both externally to the belly, and taken

taken internally; it is most conveniently exhibited in the form of pills, into which it may be reduced by mixing it with crumb of bread.

In the same manner with the oil of wormwood, the following oils, mentioned on the authority of the pharmacopœia Rossica, are also directed to be prepared.

Essential oil of orange skins. Ross.

Essence of lemons.

182

Of these essential oils, as existing in a separate state in the growing vegetable, we have already offered some observations. They are obtained in a very pure state by distillation. They are now rejected from our pharmacopœias, being employed rather as perfumes than as medicines. This is particularly the case with the essence of lemons, which is a pleasant oil, of a fine smell, very nearly as agreeable as that of the fresh peel; it is one of the lightest and most volatile essential oils we have, perfectly limpid, and almost colourless. It is taken in doses of two or three drops, as a cordial, in weakness of the stomach, &c. though more frequently useful as a perfume. It gives a fine flavour to the officinal volatile aromatic spirit of the Edinburgh college, or the compound spirit of ammonia, as it is now styled by that of the London: and it may be remarked, that it enters the formula of both colleges, altho' neither of them has given it a place among their preparations, probably as it is one of those articles which the apothecary rarely prepares for himself. When soap is given in the form of pills, by the addition of a few drops of this oil they are thought to sit more easily on the stomach.

Essential oil of cloves. Ross.

183

This oil is so ponderous as to sink in water, and is not easily elevated in distillation; if the water which comes over be returned on the remaining cloves, and the distillation repeated, some more oil will generally be obtained, though much inferior in quality to the first. The oil of cloves is usually described as being "in taste excessively hot and fiery, and of a gold yellow colour," (*Boerh. prolegg.*). Such indeed is the composition which we receive under this name from Holland; but the genuine oil of cloves is one of the milder oils; it may be taken with great safety (duly diluted) to the quantity of 10 or 12 drops or more. Nor is its colour at all yellow, unless it has been long and carelessly kept or distilled by too violent a fire: when in perfection, it is limpid and colourless, of a pleasant, moderately warm, and pungent taste and a very agreeable smell, much resembling that of the spice itself. The Dutch oil of cloves contains a large quantity of expressed oil, as evidently appears upon examining it by distillation. This, however, cannot be the addition to which it owes its acrimony. A mean proportion of a resinous extract of cloves communicates to a large one of oil a deep colour, and a great degree of acrimony.

Essential oil of camomile. Ross.

184

An oil of camomile had formerly a place in our pharmacopœias made by infusion of the recent plant, and its flowers in olive oil; and again separating it by

pressure after impregnating it with the active parts of the plant by heat. This, however, was intended only for external application; but the essential oil is meant to be used internally.

It is a very pungent oil, of a strong not ungrateful smell, resembling that of the flowers: its colour is yellow, with a cast of greenish or brown. It is sometimes given in the dose of a few drops, as a carminative, in hysterical disorders, and likewise as a vermifuge; it may be conveniently made into pills with crumb of bread.

Oil of cinnamon. Ross.

185

This valuable oil is extremely hot and pungent, of a most agreeable flavour, like that of the cinnamon itself. In cold languid cases, and debilities of the nervous system, it is one of the most immediate cordials and reteratives. The dose is one, two, or three drops; which must always be carefully diluted by the mediation of sugar, &c.: for so great is the pungency of this oil, that a single drop let fall upon the tongue, undiluted, produces as Boerhaave observes, a gangrenous eschar. In the distillation of this oil, a smart fire is required; and the low head, with a channel round it, recommended for the distillation of the less volatile oils, is particularly necessary for this, which is one of the least volatile, and which is afforded by the spice in exceeding small quantity. The distilled water retains no small portion of the oil; but this oil being very ponderous, great part of it subsides from the water, on standing for two or three weeks in a cool place.

Essential oil of fennel seeds. Ross.

186

The oil obtained from sweet fennel seeds is much more elegant and agreeable than that of the common fennel. It is one of the mildest of these preparations; it is nearly of the same degree of warmth with that of aniseeds; to which it is likewise similar in flavour, though far more grateful. It is given in two or three drops to ten or twelve, as a carminative, in cold indispotions of the stomach; and in some kinds of coughs for promoting expectoration.

Essential oil of rhodium. Ross.

187

This oil is extremely odoriferous, and principally employed as a perfume in scenting pomatums, and the like. Custom has not as yet received any preparation of this elegant aromatic wood into internal use among us.

Essential oil of mice. Ross.

188

The essential oil of mice is moderately pungent, very volatile, and of a strong aromatic smell, like that of the spice itself. It is thin and limpid, of a pale yellowish colour, with a portion of thicker and darker coloured oil at the bottom. This oil, taken internally to the extent of a few drops, is celebrated in vomiting, singultus, and colic pains; and in the same complaints it has also been advised to be applied externally to the umbilical region. It is however, but rarely to be met with in the shops.

Essential oil of marjoram. Ross.

189

This oil is very hot and penetrating, in flavour not near so agreeable as the marjoram itself; when in perfection, it is of a pale yellow colour; by long keeping,

Preparations and Compositions.

it turns reddish; if distilled with too great a heat, it rises of this colour at first. It is supposed by some to be peculiarly serviceable in relaxation, obstructions, and mucous discharges of the uterus; the dose is one or two drops.

Essential oil of nutmegs. Ross.

190 The essential oil of nutmegs possesses the flavour and aromatic virtues of the spice in an eminent degree. It is similar in quality to the oil of mace, but somewhat less grateful.

Essential oil of rue. Ross.

191 The oil of rue has a very acid taste, and a penetrating smell, resembling that of the herb, but rather more unpleasant. It is sometimes made use of in hysterical disorders and as an antehemantic; and also in epilepsies proceeding from a relaxed state of the nerves.

Rue yields its oil very sparingly. The largest quantity is obtained from it when the flowers are ready to fall off, and the seeds begin to show themselves: suitable maceration, previous to the distillation, is here extremely necessary.

Essential oil of savory. Ross.

192 Savory yields on distillation a small quantity of essential oil, of great subtilty and volatility; and it is unquestionably an active article, but among us it is not employed in medicine.

Essential oil of tanfy. Ross.

193 Tanfy yields on distillation an oil of a greenish colour inclining to yellow. It smells strongly on the herb, and possesses at least its aromatic property in a concentrated state.

Oil of wax. Dan.

194 Melt yellow bees wax with twice its quantity of sand, and distil in a retort placed in a sand-furnace. At first an acid liquor rises, and afterwards a thick oil, which sticks in the neck of the retort, unless it be heated by applying live coal. This may be rectified into a thin oil, by distilling it several times, without addition, in a sand-heat.

Boerhaave directs the wax, cut in pieces, to be put into the retort first, so as to fill one half of it; when as much sand may be poured thereon as will fill the remaining half. This is a neater, and much less troublesome way, than melting the wax, and mixing it with the sand before they are put into the retort. The author above-mentioned highly commends this oil against roughness and chaps of the skin, and other like purposes: the college of Strasburgh speak also of it being given internally, and say it is a powerful diuretic (*ingens diureticum*) in doses from two to four or more drops: but its disagreeable smell has prevented its coming into use among us.

The number of essential oils which have now a place in the London and Edinburgh pharmacopœias, and likewise in the foreign ones of modern date, is much less considerable than formerly; and perhaps those still retained afford a sufficient variety of the more active and useful oils. Most of the oils mentioned above particularly those which have a place in the London and Edinburgh pharmacopœias, are prepared by our

chemists in Britain, and are easily procurable in a tolerable degree of perfection; but the oils from the more expensive spices, though still introduced among the preparations in the foreign pharmacopœias, are, when employed among us, usually imported from abroad.

These are frequently so much adulterated, that it is not an easy matter to meet with such as are fit for use. Nor are these adulterations easily discoverable. The grosser abuses, indeed, may be readily detected: thus, if the oil be mixed with spirit of wine, it will turn milky on the addition of water; if with expell'd oils, rectified spirit will dissolve the essential, and leave the other behind; if with oil of turpentine, on dipping a piece of paper in the mixture, and drying it with a gentle heat, the turpentine will be betrayed by its smell. But the more subtle artists have contrived other methods of sophistication, which elude all trials of this kind.

Some have looked upon the specific gravity of oils as a certain criterion of their genuineness: and accordingly we have given a table of the gravity of several. This, however, is not to be absolutely depended on: for the genuine oils, obtained from the same subjects, often differ in gravity as much as those drawn from different ones. Cinnamon and cloves, whose oils usually sink in water, yield, if slowly and warily distilled, an oil of great fragrancy, which is nevertheless specifically lighter than the aqueous fluid employed in the distillation of it, while, on the other hand, the last runnings of some of the lighter oils prove sometimes so ponderous as to sink in water.

As all essential oils agree in the general properties of solubility in spirit of wine, indissolubility in water, miscibility with water by the intervention of certain intermedia, volatility in the heat of boiling water, &c. it is plain that they may be variously mixed with each other, or the dearer sophisticated with the cheaper, without any possibility of discovering the abuse by any trials of this kind. And indeed it would not be of much advantage to the purchaser, if he had infallible criteria of the genuineness of every individual oil. It is of as much importance that they be good as that they be genuine; for genuine oils, from inattentive distillation and long and careless keeping, are often weaker both in smell and taste than the common sophisticated ones.

The smell and taste seem to be the only certain test of which the nature of the thing will admit. If a bark should have in every respect the appearance of good cinnamon, and should be proved indisputably to be the genuine bark of the cinnamon-tree; yet if it want the cinnamon flavour, or has it but in a low degree, we reject it: and the case is the same with the oil. It is only from use and habit, or comparisons with specimens of known quality, that we can judge of the goodness either of the drugs themselves or of their oils.

Most of the essential oils, indeed, are too hot and pungent to be tasted with safety: and the smell of the subject is so much concentrated in them, that a small variation in this respect is not easily distinguished; but we can readily dilute them to any assignable degree. A drop of the oil may be dissolved in spirit of wine, or received on a bit of sugar, and dissolved by that intermedium in water. The quantity of liquor which it thus impregnates with its flavour, or the degree of
flavour

Preparations and Compositions.

Preparations and Compositions.

flavour which it communicates to a certain determinate quantity, will be the measure of the degree of goodness of the oil.

We shall here subjoin the result of some experiments, showing the quantity of essential oil obtained from different vegetables, reduced into the form of a table. The first column contains the names of the respective vegetable substances: the second, the quantity of each which was submitted to the distillation; and the third, the quantity of oil obtained. In every other part of this article, where *grain* weights are mentioned, the Troy pound of 12 ounces is meant: but these experiments having been all made by a pound of 16 ounces, it was thought expedient to set down the matter of fact in the original weights: especially as the several materials, in the large quantity commonly required for the

distillation of oils, are purchased by weights of the same kind. But to remove any ambiguity which might arise from hence, and to enable the reader to judge more readily of the product, a reduction of the weights is given in the next column; which shows the number of parts of each of the subjects from which one part of oil was obtained. To each article is affixed the author's name from whom the experiment was taken. The different distillations of one subject, several of which are inserted in the table, show how variable the product of oil is, and that the exotic spices, as well as our indigenous plants, do not always contain the same proportion of this active principle; though it may be observed, also, that part of the differences may probably arise from the operation itself having been more or less carefully performed.

CHAP. VII. Salts.

Diluted or weak vitriolic acid. L.

176 Take of vitriolic acid, one ounce by weight; distilled water, 8 ounces by weight. Mix them by degrees.

Weak vitriolic acid, common called weak spirit of vitriol. E.

Take of vitriolic acid, one part; water, seven parts. Mix them.

In the former editions of our pharmacopœias, directions were given for the preparation of the vitriolic acid by the apothecary himself, under the heads of *Spirit and oil of vitriol, spirit or oil of sulphur by the bell, &c.*: but as it is now found that all these modes are expensive, and that this acid may be furnished at a cheaper rate from the trading chemists preparing it on a large scale, it is with propriety that both colleges have now rejected it from the preparations, and introduced it only into the list of the materia medica.

When, however, it is of the degree of concentration there required, it can be employed for very few purposes in medicine. The most simple form in which it can be advantageously employed internally, is that in which it is merely diluted with water; and it is highly proper that there should be some fixed standard in which the acid in this state should be kept. It is, however, much to be regretted, that the London and Edinburgh colleges have not adopted the same standard with respect to strength: for in the one, the strong acid constitutes an eighth; and in the other, only a ninth of the mixture. The former proportion, which is that of the Edinburgh college, we are inclined to prefer, as it gives exactly a dram of acid to the ounce; but the dilution by means of distilled water, which is directed by the London, is preferable to spring-water: which, even in its purest state, is rarely free from impregnations in part affecting the acid.

The acid of vitriol is the most ponderous of all the liquors we are acquainted with, and the most powerful of the acids. If any other acid be united with a fixed alkaline salt or earth, on the addition of the vitriolic,

such acid will be dislodged, and arise on applying a moderate heat, leaving the vitriolic in possession of the alkali; though without this addition it would not yield to the most vehement fire. Mixed with water, it instantly creates great heat, inasmuch that glass vessels are apt to crack from the mixture, unless it be very slowly performed: exposed to the air, it imbibes moisture, and soon acquires a remarkable increase of weight. In medicine, it is employed chiefly as subservient to other preparations: it is also frequently mixed with juleps and the like, in such quantity as will be sufficient to give the liquor an agreeable tartness, and it then is a cooling antiseptic, a restringent, and a stomatic.

It is particularly useful for allaying inordinate actions of the stomach, when under the form of singultus or vomiting. For its medical properties, see ACIDS and VITRIOL.

Nitrous acid. L.

Take of purified nitre, by weight, 60 ounces; vitriolic acid, by weight, 29 ounces. Mix and distil.

197

The specific gravity of this is to the weight of distilled water as 1550 to 1000.

Nitrous acid commonly called Glauber's spirit of nitre. E.

Take of purest nitre, bruised, two pounds; vitriolic acid, one pound. Having put the nitre into a glass retort, pour on it the spirit; then distil in a sand-bath, gradually increasing the fire, till the sand-pot becomes of a dull red colour.

Hence the vitriolic acid expels the nitrous, in red corrosive vapours, which begin to issue immediately on mixture; and which the operator ought cautiously to avoid. A pound of acid of vitriol is sufficient to expel all the acid from about two pounds of nitre, not from more: some direct equal parts of the two. The spirit, in either case, is in quality the same; the difference, in this respect, affecting only the residuum. If two parts of nitre be taken to one of volatile acid, the remaining alkaline basis of the nitre is completely saturated with the vitriolic acid; and the result is a neutral salt, the same with vitriolated tartar, as we shall

Preparations and Compositions.

shall see hereafter. If more nitre be used, a part of the nitre in substance will remain blended with this neutral salt: if less nitre, it cannot afford alkali enough to saturate the vitriolic acid, and the residuum will not be a neutral salt, but a very acid one. In this last case there is one conveniency; the acid salt being readily soluble in water, so as to be got out without breaking the retort, which the others are not.

Diluted or equal nitrous acid. L.

198 Take of nitrous acid, distilled water, each one pound.
Mix them.

Weak nitrous acid. E.

Take of nitrous acid, water, equal weights. Mix them, taking care to avoid the noxious vapours.

In the old editions both of the London and Edinburgh pharmacopœias, directions were given for the preparation of aquafortis simplex and duplex; but these were no more than different forms of preparing an impure nitrous acid, unfit for medical purposes. They are therefore, with propriety, superseded by the more simple formulæ of nitrous acid and diluted or weak nitrous acid, mentioned above. In making the diluted acid, distilled water is preferable to common water.

The vapour separated during the mixing of nitrous acid and water, is the permanently elastic fluid called *nitrous acid air*, which is deleterious to animal life.

The acid of nitre is next in strength to the vitriolic, and dislodges all others from alkaline salts or earths. It differs from all the other acids in degrading with inflammable matters: if a solution of any inflammable substance, as hartshorn, &c. in this acid, be set to evaporate, as soon as the matter approaches to dryness, a violent detonation ensues. The chief use of this acid is as a menstruum for certain minerals, and as the basis of some particular preparations to be mentioned hereafter. It has been given likewise, diluted with any convenient vehicle, as a diuretic, from 10 to 50 drops.

Muriatic acid. L.

199 Take of dry sea-salt, 10 pounds; vitriolic acid, six pounds; water, five pounds. Add the vitriolic acid first mixed with the water by degrees, to the salt; then distil.

The specific gravity of this acid is to distilled water as 1170 to 1000.

Muriatic acid, commonly called spirit of sea-salt. E.

Take of sea-salt, two pounds; vitriolic acid, water, each one pound. Let the salt be first put into a pot, and brought to a red heat, that the oily impurities may be consumed; then put it into the retort. Next mix the acid with the water, and when the mixture has cooled, pour it upon the salt. Lastly, distil in a sand heat with a middling heat, as long as any acid comes over.

The marine, or muriatic acid, arises, not in red fumes like the nitrous, but in white ones. The addition of water is more necessary here than in the foregoing process; the marine vapours being so volatile, as scarcely to condense without some adventitious humidity. The acid of vitriol is most conveniently mix-

ed with the water in an earthen or stone-ware vessel: Preparation for unless the mixture be made exceedingly slow, it grows so hot as to endanger breaking a glass one.

The spirit of sea-salt is the weakest of the mineral acids, but stronger than any of the vegetable: it requires a greater fire to distil it than that of nitre, yet it is more readily dissipated by the action of the air. It is used chiefly as a menstruum for the making of other preparations; sometimes, likewise, it is given, properly diluted, as an antiphlogistic, aperient, and diuretic, from 10 to 60 or 70 drops.

Distilled vinegar.

Take of vinegar five pints. Distil with a gentle fire, in glass vessels, so long as the drops fall free from empyreuma. L.

Let eight pounds of vinegar be distilled in glass vessels with a gentle heat. Let the two first pounds that come over be thrown away as containing too much water; let four pounds next following be reserved as the distilled vinegar. What remains is a still stronger acid, but too much acted on by the heat. E.

This process may be performed either in a common still with its head, or in a retort. The better kinds of wine-vinegar should be used: those prepared from malt liquors, however fine and clear they may seem to be, contain a large quantity of a viscous substance, as appears from the sliminess and ropyness to which they are very much subject: this not only hinders the acid parts from rising freely, but likewise is apt to make the vinegar boil over into the recipient, and at the same time disposes it to receive a disagreeable impression from the fire. And indeed, with the best kind of vinegar, if the distillation be carried on to any great length, it is extremely difficult to avoid an empyreuma. The best method of preventing this inconvenience is, if a retort be used, to place the sand but a little way up its sides, and when somewhat more than half the liquor is come over, to pour on the remainder a quantity of fresh vinegar equal to the liquor drawn off. This may be repeated three or four times; the vinegar supplied at each time being previously heated. The addition, of cold liquor would not only prolong the operation, but also endanger the breaking of the retort. If the common still be employed, it should likewise be occasionally supplied with fresh vinegar in proportion as the spirit runs off; and this continued until the process can be conveniently carried no farther: the distilled spirit must be rectified by a second distillation in a retort or glass alembic; for although the head and receiver be of glass or stone-ware, the acid will contract a metallic taint from the pewter worm.

The residuum of this process is commonly thrown away as useless, although if skilfully managed, it might be made to turn to good account; the most acid parts of the vinegar still remaining in it. Mixed with about three times its weight of fine dry sand, and committed to distillation in a retort, with a well-regulated fire, it yields an exceeding strong acid spirit, together with an empyreumatic oil, which taints the spirit with a disagreeable odour. This acid is nevertheless, without any rectification, better for some purposes (as a little

of

Preparations and Compositions.

Preparations and Compositions.

of it will go a great way) than the pure spirit; particularly for making the diuretic or acetated kali of the London College; for there the oily matter, on which its ill flavour depends, is burnt out by the calcination.

The spirit of vinegar is a purer and stronger acid than vinegar itself, with which it agrees in other respects. (See VINEGAR). Their principal difference from the mineral acid consists in their being milder, less stimulating, less disposed to affect the kidneys and promote the urinary secretions, or to coagulate the animal juices. The matter left after the distillation in glass vessels, though not used in medicine, would doubtless prove a serviceable detergent saponaceous acid; and in this light stands recommended by Boerhaave.

Concentrated vinegar. Succ.

201 Let white wine vinegar be frozen in a wooden vessel in cold winter weather; and let the fluid separated from the ice be preserved for use. It may be considered as sufficiently strong, if one dram of it be capable of saturating a scruple of the fixed vegetable alkali.

This is a very easy mode for obtaining the acid of vinegar in a concentrated state, and freed from a considerable portion of its water. But at the same time we do not thus obtain the acid either so much concentrated, or in so pure a state as by the following process.

Acetous acid. L.

202 Take of verdigrise, in coarse powder, two pounds. Dry it perfectly by means of a water-bath saturated with sea-salt; then distil it in a sand-bath, and after that distil the liquor. Its specific gravity is to that of distilled water as 1050 to 1000.

By this process, it may be readily concluded that we obtain the acetous acid in its most concentrated state, and with the least admixture of water. And after the re-distillation, it may also be supposed that it will be free from all mixture of the copper. But the internal use of it has been objected to by some, on the supposition that it may still retain a portion of the metal; and hitherto it has, we believe, been but little employed.

CrySTALLIZED acid of tartar. Succ.

203 Take of prepared chalk, frequently washed with warm water, two pounds; spring water, 32 pounds. After slight boiling, by degrees add of cream of tartar 7 pounds, or as much as is sufficient for saturation. Removing the vessel from the fire, let it stand for half an hour, then cautiously pour off the clear liquor into a glass vessel. Wash the residuum or tartareous selenites by pouring water on it three or four times. To this residuum afterwards add of weak vitriolic acid 16 pounds, let it be digested for a day, frequently stirring it with a wooden spatula. After this pour the acid liquor into a glass vessel: but with the residuum mix 16 pounds of spring water; strain it through paper, and again pour water on the residuum till it become insipid. Let the acid liquors mixed together in a glass vessel be boiled to the consistence of a thin syrup; which being strained, must be set apart for the formation of crystals. Let the crystals collected after repeated distillations

be dried on paper, and afterwards kept in a dry place.

If before crystallization a little of the inspissated acid liquor be diluted with four times its quantity of pure water, and a few drops of vinegar of litharge be put into it, a white sediment will immediately be deposited. If a few drops of the diluted nitrous acid be then added, the mixture will become sapid, if the tartareous liquor be pure and entirely free from the vitriolic acid; but if it be not, it will become white. This fault, however, may be corrected, if the acid of tartar be diluted with six pounds of water and a few ounces of the tartareous selenites be added to it. After this it may be digested, strained, and crystallized.

By this process, the acid of tartar may be obtained in a pure solid form. It would, however, be perhaps an improvement of the process, if quicklime were employed in place of chalk. For Dr Black has found that quicklime absorbs the whole of the tartareous acid, and then the supernatant liquor contains only the alkaline part of the tartar; whereas, when chalk is employed, it contains a solution of soluble tartar, the chalk taking up only the superabundant acid. By this method then a greater quantity of tartareous acid might be obtained from the sediment. The tartareous acid has not hitherto been much employed in its pure state. But besides being useful for some purposes in medicine, for which the cream of tartar is at present in use, and where that super-saturated neutral may be less proper, there is also reason to suppose, that from the employment of the pure acid, we should arrive at more certainty in the preparation of the antimonium tartarizatum, or tartar emetic, than by employing the cream of tartar, the proportion of acid in which varies very much from different circumstances. The pure acid of tartar might also probably be employed with advantage for bringing other metallic substances to a saline state.

Distilled acid of tartar. Succ.

Let pounded crude tartar be put into a tubulated earthen or iron retort till it fills about two-thirds of it, and let distillation be performed by gradually increasing the heat. Into the recipient, which should be very large, an acid liquor will pass over together with the oil; which being separated from the oil, must again be distilled from a glass retort. If the residuum contained in the earthen or iron retort be diluted with water, strained through paper, and boiled to dryness, it gives what is called the *alkali* of tartar. If this do not appear white, it may be made so by burning, solution, straining, and evaporation.

This is another mode of obtaining both the acid and alkali of tartar in a pretty pure state; and, as well as the former, it is not unworthy of being adopted into our pharmacopœias.

Aerated water. Ross.

Let spring water be saturated with the fixed air, or aerial acid, arising from a solution of chalk in vitriolic acid, or in any similar acid. Water may also be impregnated by the fixed air rising from fermenting liquors.

The aerial acid, on which we have already had occasion

tc

to make some observations, besides the great influence which it has as affecting different saline bodies into whose composition it enters, is also frequently employed in medicine, with a view to its action on the human body. The late ingenious Dr DeBson, in his Commentary on Fixed Air, has pointed out many purposes for which it may be usefully employed, and several different forms under which it may be used. But there is no form under which it is at present more frequently had recourse to than that of aerated or mephitic water, as it has often been called. And although not yet received either into the London or Edinburgh pharmacopœias, it is daily employed in practice, and is we think justly intitled to a place among the saline preparations.

The most convenient mode of impregnating water with the aerial acid, and thus having it in our power to exhibit that acid as it were in a diluted state, is by means of a well known and sufficiently simple apparatus, contrived by that ingenious philosopher Dr Neoth. Such a machine ought, we think, to be kept in every shop for the more ready preparation of this fluid. Water properly impregnated with the aerial acid has an agreeable acidulous taste. It is often employed with great advantage in the way of common drink, by those who are subjected to stomach complaints, and by calculous patients. But, besides this, it furnishes an excellent vehicle for the exhibition of many other medicines.

Besides the simple aerated water, the Pharmacopœia Roslica contains also an aqua aëris fixi marialis, or ferruginous aerated water. This is prepared by suspending iron wires in that water till the water be fully saturated with the metal. And in consequence of this acid, simple water becomes a menstruum both for different metallic and earthy substances. But water in this state may be considered rather as fitted for those purposes for which chalybeates are in use, than as a preparation of the aerial acid.

Salt and oil of amber. L.

206

Take of amber two pounds. Distil in a sand heat, gradually augmented; an acid liquor, oil, and salt impregnated with oil, will ascend.

On this article we have already offered some observations under the head of Essential Oils. The directions here given by the London college differ chiefly from those of the Edinburgh college formerly mentioned, in no sand being employed: But when care is taken that the sand be pure, it can give no improper impregnation to the medicine, and may prevent some inconveniences in the distillation, particularly that of the amber rising in substance into the receiver.

Purified salt of amber. L.

207

Take of salt of amber half a pound; d distilled water, one pint. Boil the salt in the distilled water, and set aside the solution to crystallize.

Salt of amber, when perfectly pure, is white, of an acid taste, and not ungrateful. It requires, for its solution, of cold water, in summer, about twenty times its weight; and of boiling water about twice its weight; it is scarcely soluble in rectified spirit without the assistance of heat.

It is given as a cooling diuretic in doses of a few grains, and also in hysterical compositions.

Preparations and Compositions.

Flowers of benzoin.

228

Take of benzoin, in powder, one pound. Put it into an earthen pot, placed in sand; and, with a slow fire, sublime the flowers into a paper cone fitted to the pot.

If the flowers be of a yellow colour, mix them with white clay, and sublime them a second time. L.

Put any quantity of powdered benzoin into an earthen pot, to which, after fitting it with a large conical paper cap, apply a gentle heat that the flowers may sublime. If the flowers be impregnated with oil, let them be purified by solution in warm water and crystallization. L.

Benzoin, exposed in a retort to a gentle fire, melts, and sends up into the neck white, shining crystalline flowers, which are followed by an oily substance. These flowers, which are at present considered as a peculiar acid, are by some termed *acidum benzoicum*. On raising the heat a little (a recipient being applied to the neck of the retort), a thin yellowish oil comes over, intermingled with an acid liquor, and afterwards a thick butyraceous substance: this last, liquified in boiling water, gives out to it a considerable quantity of saline matter (separable by filtration and proper exhalation), which appears in all respects similar to the flowers.

It appears, therefore, that the whole quantity of flowers which benzoin is capable of yielding, cannot be obtained by the above processes, since a considerable portion arises after the time of their being discontinued. The greatest part of the flowers arise with a less degree of heat than what is necessary to elevate the oil; but if the operation be hastily conducted, or if the fire be not exceedingly gentle, the oil will arise along with the flowers, and render them foul. Hence in the way of trade, it is extremely difficult to prepare them of the requisite whiteness and purity; the heat which becomes necessary, when large quantities of the benzoin are employed, being so great as to force over some of the oil along with them.

In order, therefore, to obtain these flowers in perfection, only a small quantity of benzoin should be put into the vessel at a time; and that this may not be any impediment to the requisite dispatch, a number of shallow, flat bottomed, earthen dishes may be employed, each fitted with another vessel inverted over it, or a paper cone. With these you may fill a sand furnace; having fresh dishes changed in readiness to replace those in the furnace, as soon as the process shall appear finished in them: the residuum of the benzoin shall be scraped out of each of the vessels before a fresh parcel be put in.

These flowers, when made in perfection, have an agreeable taste and fragrant smell. They totally dissolve in spirit of wine; and likewise by the assistance of heat, in water; but separate again from the latter upon the liquor's growing cold, shooting into saline spicula, which unite together into irregular masses. By the mediation of sugar they remain suspended in cold water, and thus form an elegant balsamic syrup. Some have held them in great esteem as pectoral and sudorific

Preparations and Compositions.

fudorific, in the dose of half a scruple or more; but at present they are rarely used, on account of the offensive oil which, as usually prepared, they are tainted with, and from which a fresh sublimation from tobacco-pipe clay, as formerly practised, did not free them so effectually as might be wished. The observations above related, point out the method of depurating them more perfectly, viz. by solution, filtration, and crystallization.

They enter the composition of the paregoric elixir, or tinctura opii camphorata, as it is called.

Salt of Tartar. E.

209 Take of tartar, what quantity you please. Roll it up in a piece of moist bibulous paper, or put it into a crucible, and surrounding it with live coals, burn it to a coal; next, having beat this coal, calcine it in an open crucible with a moderate heat, taking care that it do not melt, and continue the calcination till the coal becomes of a white, or at least of an ash, colour. Then dissolve it in warm water; strain the liquor through a cloth, and evaporate it in a clean iron vessel; diligently stirring it towards the end of the process with an iron spatula, to prevent it from sticking to the bottom of the vessel. A very white salt will remain, which is to be left a little longer on the fire, till the bottom of the vessel becomes almost red. Lastly, when the salt is grown cold, let it be put up in glass vessels well shut.

Native tartar is a saline substance, compounded of an acid, of a fixed alkali, and of oily viscous, and colouring matter. The purpose of the above process is, to free it from every other matter but the fixed alkali. From the mistaken notion that tartar was essentially an acid mixed only with impurities, it has been generally supposed that the effect of this operation was the conversion of an acid into an alkali by means of heat. But since Mr Scheele has discovered that the proper matter of tartar, freed from the oily and colouring parts is really a salt compounded of an acid, which is predominant, and a fixed alkali, we have no farther need of such an obscure theory. The acid of the tartar by this process is dissipated by means of the heat; and the oily, viscous, and colouring matters, are partly dissipated, and partly brought to the state of insoluble earthy matter, easily separable by the future lixiviation from the alkali, wherewith they were loosely combined. But by the last of those processes, something farther is carried on than the separation of the more palpable foreign matters. By allowing the salt, freed from the water of the lixivium, to remain on the fire till the bottom of the vessel become almost red, any oily matter that may still be present seems to be decomposed by the united action of the heat and fixed alkali, forming with a part of the latter, by their reciprocal action, a volatile alkaline salt, which is forthwith discharged in elastic vapours. Besides the complete discharge of the above principles, the remaining fixed alkali also suffers a considerable loss of its fixed air, or aerial acid; with which, when fully saturated, it forms the imperfect neutral salt, denominated by Dr Black *mild fixed alkali*: on this account it is somewhat caustic, considerably deliquescent, and in proportion to its possessing these properties more or less, it more or less nearly approaches to the state of pure alkali. It is not, how-

VOL. XIV.

ever, so effectually deprived of fixed air as to be sufficiently caustic for a number of purposes. Where causticity is not required, the salt thus purified is abundantly fit for most pharmaceutical purposes; but as native tartar generally contains small portions of neutral salts besides the foreign matters already noticed, it is necessary if we wish to have a very pure alkali for nice operations, to employ crystallization and other means, beside the process here directed.

The white and red sorts of tartar are equally fit for the purpose of making fixed salt; the only difference is, that the white affords a somewhat larger quantity than the other; from 16 ounces of this sort, upwards of four ounces of fixed alkaline salt may be obtained. The use of the paper is to prevent the smaller pieces of the tartar from dropping down into the ash-hole, through the interstices of the coals, upon first injecting it into the furnace.

The calcination of the salt (if the tartar was sufficiently burnt at first) does not increase its strength so much as is supposed: nor is the greenish or blue colour any certain mark either of its strength, or of its having been, as was formerly supposed, long exposed to a vehement fire: for if the crucible be perfectly clean, close covered, and has stood the fire without cracking, the salt will turn out white, though kept melted and reverberated ever so long; while, on the other hand, a slight crack happening in the crucible, or a spark of coal falling in, will in a few minutes give the salt the colour admired. The colour in reality is a mark rather of its containing some inflammable matter than of its strength.

The vegetable alkali prepared from tartar has now no place in the London pharmacopœia, or at least it is included under the following article.

Prepared kali. L.

Take of pot-ash, two pounds; boiling distilled water, three pints. Dissolve and filtre through paper; evaporate the liquor till a pellicle appears on the surface; then set it aside for a night, that the neutral-salts may crystallize; after which pour out the liquor, and boil away the whole of the water, constantly stirring, lest any salt should adhere to the pot. In like manner is purified impure kali from the ashes of any kind of vegetable. The same salt may be prepared from tartar burnt till it becomes of an ash-colour.

Fixed vegetable alkaline salt purified. E.

Let the fixed alkaline salt, called in English *pearl-ashes*, be put into a crucible, and brought to a somewhat red heat, that the oily impurities, if there be any, may be consumed; then having beat and agitated it with an equal weight of water, let them be well mixed. After the feces have subsided, pour the ley into a very clean iron pot, and boil to dryness, diligently stirring the salt towards the end of the process, to prevent its sticking to the vessel. This salt, if it hath been rightly purified, though it be very dry, if rubbed with an equal weight of water, may be dissolved into a liquor void of colour or smell.

The potash used in commerce is an alkali mixed with a considerable quantity of remaining charcoal, U u sulphur,

Preparations and Compositions.

210

211

Preparations and Compositions.

ful; hur, vitriolated tartar, and oily matter. In the large manufactures, the alkaline part is indeed considerably freed from impurities by mixing the weed-ashes with water, evaporating the clear ley, and burning the residuum in an oven; but besides that this process is insufficient for the complete separation of the impurities, it also superadds a quantity of stony matter, giving to the alkali the *pearl* appearance (whence its name), and rendering it altogether unfit for pharmaceutical purposes. By the processes here directed, the alkali is effectually freed from all these heterogeneous matters, excepting perhaps a small proportion of vitriolated tartar, or other neutral salts, which may very generally be neglected. As in the process no after calcination is directed, it is probable that the fixed alkali thus prepared will not prove so caustic, that is to say, is not so considerably deprived of fixed air, as in the process directed for preparing the salt of tartar. It is, however sufficiently pure for most purposes; and we consider the above process as the most convenient and cheap method of obtaining the vegetable fixed alkali in its mild state.

The purified vegetable alkali has been known in our pharmacopœias under the different names of *salt of sorrel-wood*, *salt of tartar*, &c. But all these being now known to be really the same, the terms, as leading to error, have been with justice expunged; and it has been a desideratum to discover some short name equally applicable to the whole. The term employed by the Edinburgh college is too long, being rather a description than a name; but to that employed by the London college, *Kali*, objections have also been made. And it must be allowed, that besides the inconvenience which arises from its being an indeclinable word, the fossil alkali is equally intitled to the same appellation. Besides this, as a considerable portion of the fossil alkali is prepared from burning a vegetable growing on the sea coasts, which has the name of *kali*, the *Kali spinosum* of Linné, some apparent contradiction and ambiguity may thence arise. And the London college would perhaps have done better, if they had adopted the term *Potassa*; a name which has been appropriated to this salt by some of the most eminent modern chemists.

The purified potassa is frequently employed in medicine in conjunction with other articles, particularly for the formation of saline neutral draughts and mixtures: But it is used also by itself in doses from three or four grains to 15 or 20; and it frequently operates as a powerful diuretic, particularly when aided by proper dilution. See *PEARL-ASH* and *POT-ASH*.

Water of kali. L.

212 Take of kali, one pound, set it by in a moist place till it be dissolved, and then strain it.

This article had a place in former editions of our pharmacopœias under the titles of *ley of tartar* or *oil of tartar per deliquium*, &c. It is however to be considered as a mere watery solution of the mild vegetable alkali, formed by its attracting moisture from the air; and therefore it is with propriety styled the *water of kali*.

The solutions of fixed alkaline salts, made by exposing them to a moist air, are generally considered

as being purer than those made by applying water directly; for though the salt be repeatedly dissolved in water, filtered, and exsiccated; yet, on being li-quefied by the humidity of the air, it will still deposite a portion of earthy matter: but it must be observed, that the exsiccated salt leaves always an earthy matter on being dissolved in water, as well as on being deliquated in the air. Whether it leaves more in the one way than in the other, is not determined with precision. The deliquated lixivium is said to contain nearly one part of alkaline salt to three of an aqueous fluid. It is indifferent, in regard to the lixivium itself, whether the white ashes of tartar, or the salts extracted from them, be used; but as the ashes leave a much greater quantity of earth, the separation of the ley proves more troublesome.

The water of kali of the present edition of the London pharmacopœia, than may be considered as an improvement of the lixivium tartari of their former edition. But the Edinburgh college, considering this solution as being in no respect different from that made by pure water, have entirely rejected this preparation from their pharmacopœia, and probably with justice.

Water of pure kali. L.

Take of kali, four pounds; quicklime, six pounds; distilled water four gallons. Put four pints of water to the lime, and let them stand together for an hour; after which, add the kali and the rest of the water; then boil for a quarter of an hour: suffer the liquor to cool, and strain. A pint of this liquor ought to weigh 16 ounces. If the liquor effervesces with any acid, add more lime.

A preparation similar to this had a place in the former edition of the London pharmacopœia, under the title of *soap-ley*. Quicklime, by depriving the mild alkali of its aerial acid, renders it caustic; hence this ley is much more acrimonious, and acts more powerfully as a menstruum of oils, fats, &c. than a solution of the potassa alone. The lime should be used fresh from the kiln; by long keeping, even in close vessels, it loses its strength; such should be made choice of as is thoroughly burnt or calcined, which may be known by its comparative lightness.

All the instruments employed in this process should be either of wood, earthen ware, or glass; the common metallic ones would be corroded by the ley, so as either to discolour or communicate disagreeable qualities to it. It should be needful to filter or strain the liquor, care must be taken that the filter or strainer be of vegetable matter: woollen, silk, and that sort of filtering paper which is made of animal substances, are quickly corroded and dissolved by it.

The liquor is most conveniently weighed in a narrow-necked glass bottle, of such a size, that the measure of a wine pint may arise some height into its neck; the place to which it reaches being marked with a diamond. A pint of the common leys of our soap-makers weighs more than 16 ounces; it has been found that their soap-ley will be reduced to the standard here proposed, by mixing it with something less than an equal measure of water.

Although this liquor is indeed pure alkali dissolved in water, yet we are inclined to give the preference

Preparations and Compositions.

Prepara-
tions and
Composi-
tions.

to the name employed by the Edinburgh college, as well as to the modes of preparing it, directed in the following formula.

Cautic ley. E.

214 Take of fresh burnt quicklime, eight ounces; purified fixed vegetable alkaline salt, six ounces. Throw the quicklime, with 28 ounces of warm water, into an iron or earthen vessel. The ebullition, and extinction of the lime being perfectly finished, instantly add the alkaline salt; and having thoroughly mixed them, shut the vessel till it cools. Stir the cooled matter, and pour out the whole into a glass funnel, whose throat must be stopped up with a piece of clean rag. Let the upper mouth of the funnel be covered, while the tube of it is inserted into a glass vessel, so that the ley may gradually drop through the rag into that vessel. When it first gives over dropping, pour into the funnel some ounces of water; but cautiously, and in such a manner, that the water shall swim above the matter. The ley will again begin to drop, and the affusion of water is to be repeated in the same manner, until three pounds have dropped, which takes up the space of two or three days; then agitating the superior and inferior parts of the ley together, mix them, and put up the liquor in a well shut vessel.

If the ley be rightly prepared, it will be void of colour or smell: nor will it raise an effervescence with acids except perhaps a very slight one. Colour and odour denote the salt not sufficiently calcined; and effervescence, that the quicklime has not been good.

The reasons and propriety of the different steps in the above process will be best understood by studying the theory on which it is founded. The principle of mildness in all alkaline salts, whether fixed or volatile, vegetable or fossil, is very evidently fixed air, or the aerial acid: But as quicklime has a greater attraction for fixed air than any of these salts, so if this substance be presented to any of them, they are thereby deprived of their fixed air, and forthwith become caustic. This is what precisely happens in the above processes. The propriety of closely shutting the vessels through almost every step of the operation, is sufficiently obvious; viz. to prevent the absorption of fixed air from the atmosphere, which might defeat our intentions. When only a piece of cloth is put into the throat of the funnel, the operation is much more tedious, because the pores of the cloth are soon blocked up with the wet powdery matter. To prevent this, it may be convenient to place above the cloth a piece of fine Fly's wirework; but as metallic matters are apt to be corroded, the method used by Dr Black is the most eligible. The doctor first drops a rugged stone into the tube of the funnel, in a certain place of which it forms itself a firm bed, while the inequalities on its surface afford interstices of sufficient size for the passage of the filtering liquor. On the upper surface of this stone he puts a thin layer of lint or clean tow; immediately above this, but not in contact with it, he drops a stone similar to the former and of a size proportioned to the swell in the

upper part of the tube of the funnel. The interstices between this second stone and the funnel are filled up with stones of a less dimension, and the gradation uniformly continued till pretty small sand is employed. Finally, this is covered with a layer of coarser sand and small stones to sustain the weight of the matter, and to prevent its being invaded in the minute interstices of the fine sand. The throat of the funnel being thus built up, the stony fabric is to be freed of clay and other adhering impurities, by making clean water pass through it till the water comes clear and transparent from the extremity of the funnel. It is obvious, that in this contrivance, the author has, as usual copied nature in the means she employs to depurate watery matters in the bowels of the earth; and it might be usefully applied for the filtration of various other fluids.

It is a very necessary caution to pour the water gently into the funnel: for if it be thrown in a forcible stream, a quantity of the powdery matter will be washed down, and render all our previous labour useless. That part of the ley holding the greatest quantity of salt in solution will no doubt be heaviest, and will consequently sink lowest in the vessel: the agitation of the ley is therefore necessary, in order to procure a solution of uniform strength through all its parts. If the salt has been previously freed of oily and other inflammable matters, this ley will be colourless and void of smell. If the quicklime has been so effectually deprived of its own fixed air, as to be able to absorb the whole of that in the alkali, the ley will make no effervescence with acids, being now deprived of fixed air, to the discharge of which by acids this appearance is to be ascribed in the mild or aerated alkalis.

The caustic ley is therefore to be considered as a solution of pure alkali in water. See the article FIXED AIR.

It may be proper to observe, for the sake of understanding the whole of the theory of the above process, that while the alkali has become caustic, from being deprived of fixed air by the quicklime, the lime has in its turn become mild and insoluble in water from having received the fixed air of the alkali.

The caustic ley, under various pompous names, has been much used as a lithontriptic; but its fame is now beginning to decline. In acidities in the stomach, attended with much flatulence and laxity, the caustic ley is better adapted than mild alkalis; as in its union with the acid matter it does not separate air. When covered with mucilaginous matters, it may be safely taken into the stomach: and by stimulating, it coincides with the other intentions of cure; by some dyspeptic patients it has been employed with advantage.

Pure kali. L.

Take of water of pure kali, one gallon. Evaporate it to dryness; after which let the salt melt on the fire, and pour it out. 215

The strongest common caustic. E.

Take of caustic ley, what quantity you please. Evaporate it in a very clean iron vessel on a gentle fire till, 216

Prepara-
tions and
Composi-
tions.

till, on the ebullition ceasing, the saline matter gently flows like oil, which happens before the vessel becomes red. Pour out the caustic thus liquefied on a smooth iron plate; let it be divided into small pieces before it hardens, which are to be kept in well-stopt phials.

These preparations may be considered as differing in no essential particular. But the directions given by the Edinburgh college are the most precise and distinct.

The effect of the above processes is simply to discharge the water of the solution, whereby the causticity of the alkali is more concentrated in any given quantity. These preparations are strong and sudden caustics. The caustic prepared in this way has an inconvenience of being apt to liquefy too much on the part to which it is applied, so that it is not easily confined within the limits in which it is intended to operate; and indeed the suddenness of its action depends on this disposition to liquefy.

Lime with pure kali. L.

- 217 Take of quicklime, five pounds and four ounces; water of pure kali, 16 pounds by weight. Boil away the water of pure kali to a fourth part; then sprinkle in the lime, reduced to powder by the addition of water. Keep it in a vessel close stopp'd.

The milder common caustic. E.

- 218 Take of caustic ley, what quantity you please. Evaporate in an iron vessel till one third remains; then mix with it as much new slaked quicklime as will bring it to the consistence of pretty solid pap, which is to be kept in a vessel closely stopp'd.

These preparations, do not essentially differ from each other, while the chief difference between the present formula, and that which stood in the last edition of the London pharmacopœia is in the name. It was then styled the *strongest common caustic*.

Here the addition of lime in substance renders the preparation less apt to liquefy than the foregoing, and consequently it is more easily confinable within the intended limits, but proportionally slower in its operation. The design of keeping or of slaking the lime is, that its acrimony may be somewhat abated.

Exposed long to the air, these preparations gradually resume their power of effervescence, and lose proportionally the additional activity which the quicklime had produced in them.

Prepared natron. L.

- 219 Take of barilla, powdered, two pounds; distilled water, one gallon. Boil the barilla in four pints of water for half an hour, and strain. Boil that part which remains after straining with the rest of the water, and strain. Evaporate the mixed liquors to two pints, and set them by for eight days; strain this liquor again; and, after due boiling, set it aside to crystallize. Dissolve the crystals in distilled water; strain the solution, boil, and set it aside to crystallize.

The name of *natron*, here used by the London college for the fixed fossil alkali, has, as well as their name for the vegetable alkali, been objected to. And though they are here supported by the authority of

the ancients, yet perhaps they would have done better in following the best modern chemists by employing the term *salt of soda*. This article differs in name only from the following.

Fixed fossil alkaline salt purified. E.

- 220 Take of ashes of Spanish kali, commonly called *soda* or *barilla*, as much as you please. Bruise them; then boil in water till all the salt be dissolved. Strain this through paper, and evaporate in an iron vessel, so that after the liquor has cooled the salt may concreate into crystals.

By the above processes, the fossil alkali is obtained sufficiently pure, being much more disposed to crystallize than the vegetable alkali; the admixture of this last, objected to by Dr Lewis, is hereby in a great measure prevented.

It is with great propriety, that in this, as well as many other processes, the London college direct the use of distilled water, as being free from every impregnation.

The natron, or fossil alkali, is found lying on the ground in the island of Teneriffe, and some other countries. The native productions, of this salt seem to have been better known to the ancients than to late naturalists; and it is, with good reason, supposed to be the nitre of the Bible. How far the native natron may supersede artificial means to procure it from mixed bodies, we have not been able to learn with certainty.

The fossil alkali is not only a constituent of different neutrals, but is also sometimes employed as a medicine by itself. And in its purified state it has been by some reckoned useful in affections of the scrofulous kind. See NATRUM.

Prepared ammonia. L.

- 221 Take of sal ammoniac, powdered one pound; prepared chalk, two pounds. Mix and sublime.

Water of ammonia. L.

- 222 Take of sal ammoniac, one pound; pot-ash, one pound and a half; water, four pints. Draw off two pints by distillation, with a slow fire.

Volatile alkali from sal ammoniac, commonly called *volatile sal ammoniac*.

- 223 Take of sal ammoniac, one pound; chalk, very pure and dry, two pounds; mix them well, and sublime from a retort into a refrigerated receiver.

Spirit of Sal ammoniac. E.

- 224 Take sal ammoniac, purified vegetable fixed alkali, of each sixteen ounces; water, two pounds. Having mixed the salts, and put them into a glass retort, pour in the water; then distil to dryness with a sand-bath, gradually raising the heat.

These articles, which in the last edition of the London pharmacopœia were styled *the volatile salt and spirit of sal ammoniac*, were then directed to be prepared in the same manner.

Sal ammoniac is a neutral salt, composed of volatile alkali and marine acid. In these processes the acid is absorbed by the fixed alkali or chalk; and the volatile alkali is of course set at liberty.

The volatile alkali is, however, in its mild-state, being

Prepara-
tions and
Composi-
tions.

being combined with the fixed air, or discharged from the fixed alkali or chalk on their uniting with the muriatic acid.

The fixed alkali begins to act on the sal ammoniac, and extricates a pungent urinous odour as soon as they are mixed. Hence it is most convenient not to mix them till put into the distilling vessel. The two salts may be dissolved separately in water, the solutions poured into a retort, and a receiver immediately fitted on. An equal weight of the fixed salt is fully, perhaps more than sufficient to extricate all the volatile.

Chalk does not begin to act on the sal ammoniac till a considerable heat be applied. Hence they may be without inconvenience, and indeed ought to be thoroughly mixed together before they are put into the retort. The surface of the mixture may be covered with a little more powdered chalk, to prevent such particles of the sal ammoniac as may happen to lie uppermost from subliming unchanged. Though the fire must here be much greater than when fixed alkaline salt is used, it must not be strong, nor suddenly raised; for if it be, a part of the chalk (though of itself not capable of being elevated by any degree of heat) will be carried up along with the volatile salt. M. du Hamel experienced the justness of this observation. He relates in the Memoirs of the French Academy of Sciences for the year 1735, that he frequently found his volatile salt, when a very strong fire was used in the sublimation, amount to more, sometimes by a half, than the weight of the crude sal ammoniac employed; and although not three fourths of this concrete are pure volatile salt, yet the fixed earthy matter, when once volatilized by the alkali, rose along with it again on the gentlest resublimation, dissolved with it in water, and exhaled with it in the air.

When all the salt has sublimed, and the receiver grown cool, it may be taken off, and luted to another retort charged with fresh materials. This process may be repeated till the recipient appears lined with volatile salt to a considerable thickness: the vessel must then be broken in order to get out the salt.

The volatile salt and spirit of sal ammoniac are the purest of all the medicines of this kind. They are somewhat more acrimonious than those produced directly from animal substances, which always contain a portion of the oil of the subject, and receive from thence some degree of a saponaceous quality. These last may be reduced to the same degree of purity by combining them with acids into ammoniacal salts, and afterwards recovering the volatile alkali from these compounds by the processes above directed.

The matter which remains in the retort after the distillation of the spirit, and sublimation of the volatile sal ammoniac, is found to consist of marine acid united with the fixed alkali or chalk employed. When fixed alkaline salt has been used as the intermedium, the residuum, or *caput mortuum* as it is called, yields, on solution and crystallization, a salt exactly similar to the spirit of sea-salt coagulated afterwards described; and hence we may judge of the extraordinary virtues formerly attributed to this salt under the names of *sal antihystericum*, *antihypochondriacum*, *febrifugum*, *digestivum Sylvii*, &c.

The *caput mortuum* of the volatile salt, where chalk is employed as an intermedium, exposed to a moist air,

runs into a pungent liquor, which proves nearly the same with a solution of chalk made directly in the marine acid. It is called by some *oil of creta*, oil of chalk. If calcined shells, or other animal limes, be mingled with sal ammoniac, a mass will be obtained, which likewise deliquesces in the air, and forms a liquor of the same kind.

Water of pure ammonia. L.

Take of sal ammoniac, one pound; quicklime, two pounds; water one gallon. Add to the lime two pints of the water. Let them stand together an hour: then add the sal ammoniac and the other six pints of water, boiling, and immediately cover the vessel. Pour out the liquor when cold, and distil off with a slow fire one pint.

Cautic volatile alkali, commonly called *spirit of sal ammoniac with quicklime. E.*

Take of quicklime, fresh burnt, two pounds; water, one pound. Having put the water into an iron or stone-ware vessel, add the quicklime previously beat; cover the vessel for 24 hours; when the lime has fallen into a fine powder, put it into the retort; then add 16 ounces of sal ammoniac, diluted with four times its weight of water; and, shutting the mouth of the retort, mix them together by agitation. Lastly, distil it into a refrigerated receiver, with a very gentle heat, so that the operator can easily bear the heat of the retort applied to his hands. Twenty ounces of liquor are to be drawn off. In this distillation the vessels are to be so luted as thoroughly to exclude the vapours, which are very penetrating. After the distillation, however, they are to be opened, and the alkali poured out before the retort hath altogether cooled.

The theory of this process is precisely the same with that directed for the preparation of caustic ley. The effect of the quicklime on the sal ammoniac is very different from that of the chalk and fixed alkali in the foregoing process. Immediately on mixture a very penetrating vapour exhales; and in distillation the whole of the volatile salt arises in a liquid form, no part of it appearing in a concrete state, how gently soever the liquor be re-distilled. This spirit is far more pungent than the other both in smell and taste; and, like fixed alkalis rendered caustic by the same intermedium, it raises no effervescence on mixture with acids. The whole of the phenomena are to be ascribed to the absorption of fixed air from the alkali by means of the quicklime; and from being thus deprived of the aerial acid the volatile alkali is brought to a caustic state.

This spirit is held to be too acrimonious for internal use, and has therefore been chiefly employed for smelling to in faintings, &c. though when properly diluted it may be given inwardly with safety. It is a powerful menstruum for some vegetable substances, as Peruvian bark, from which the other spirits extract little. It is also most convenient for the purpose of rendering oils miscible with water, as in the preparation of what is called in extemporaneous practice *the oily mixture*.

Some have mixed a quantity of this with the official spirits both of sal ammoniac and of hartshorn; which thus become more pungent, so as to bear an addition

Prepara-
tions and

tions.

addition a considerable quantity of water, without any danger of the discovery from the taste or smell. This abuse would be prevented, if what has been formerly laid down as a mark of the strength of these spirits) some of the volatile salt remaining undissolved in them, were attended to. It may be detected by adding to a little of the suspected spirit about one-fourth its quantity or more of rectified spirit of wine; which, if the volatile spirit be genuine, will precipitate a part of its volatile salt, but occasions no visible separation or change in the caustic spirit, or in those which are sophisticated with it.

Others have substituted for the spirit of sal ammoniac a solution of crude sal ammoniac and fixed alkaline salt mixed together. This mixture deposits a saline matter on the addition of spirit of wine, like the genuine spirit; from which, however, it may be distinguished, by the salt which is thus separated not being a volatile alkaline, but a fixed neutral salt. The abuse may be more readily detected by a drop or two of solution of silver in aquafortis, which will produce no change in the appearance of the true spirit, but will render the counterfeit turbid and milky.

The volatile liquor, salt, and oil, of hartshorn. L.

227 Take of hartshorn, ten pounds. Distil with a fire gradually increased. A volatile liquor, salt, and oil, will ascend. The oil and salt being separated, distil the liquor three times. To the salt add an equal weight of prepared chalk, and sublime thrice, or till it become white.

The same volatile liquors, salt and oil, may be obtained from any parts (except the fat) of all kinds of animals.

The volatile alkali obtained from hartshorn, whether in a solid or fluid state, is precisely the same with that obtained from sal ammoniac. And as that process is the easiest, the Edinburgh college have entirely rejected the present. While, however, the names of spirit and salt of hartshorn are still in daily use, ammonia, or the volatile alkali, is still prepared from bones and other animal substances by several very extensive traders.

The wholesale dealers have very large pots for the distillation of hartshorn, with earthen heads almost like those of the common still; for receivers, they use a couple of oil jars, the mouths of which are luted together; the pipe that comes from the head enters the lowermost jar through a hole made on purpose in its bottom. When a large quantity of the subject is to be distilled, it is customary to continue the operation for several days successively; only unluting the head occasionally to put in fresh materials.

When only a small quantity of spirit or salt is wanted, a common iron pot, such as is usually fixed in sand furnaces, may be employed, an iron head being fitted to it. The receiver ought to be large, and a glass, or rather tin adpopter, inserted between it and the pipe of the head.

The distilling vessel being charged with pieces of the horn, a moderate fire is applied, which is slowly increased, and raised at length almost to the utmost degree. At first a watery liquor arises, the quantity of which will be smaller or greater according as the horns were more or less dry; this is succeeded by the salt and oil: the salt at first dissolves as it comes over in

the phlegm, and thus forms what is called *spirit*. When the phlegm is saturated, the remainder of the salt concretes in a solid form to the sides of the recipient. If it be required to have the whole of the salt solid and undissolved, the phlegm should be removed as soon as the salt begins to arise, which may be known by the appearance of white fumes; and that this may be done the more commodiously, the receiver should be left unluted till this first part of the process be finished. The white vapours which now arise sometimes come with such violence as to throw off or burst the receiver. To prevent this accident, it is convenient to have a small hole in the luting, which may be occasionally stopped with a wooden peg, or opened, as the operator shall find proper. After the salt has all arisen, a thick dark-coloured oil comes over. The process is now to be discontinued; and the vessels, when grown cold, unluted.

All the liquid matters being poured out of the receiver, the salt which remains adhering to its sides is to be washed out with a little water and added to the rest. It is convenient to let the whole stand for a few hours, that the oil may the better disengage itself from the liquor, so as to be first separated by a funnel, and afterwards more perfectly by filtration through wet paper. The salt and spirits are then to be farther purified as above directed.

The spirit of hartshorn met with in the shops is extremely precarious in point of strength; the quantity of salt contained in it (on which its efficacy depends) varying according as the distillation in rectifying it is continued for a longer or shorter time. If after the volatile salt has arisen, so much of the phlegm or watery part be driven over as is just sufficient to dissolve it, the spirit will be fully saturated, and as strong as it can be made. If the process be not at this instant stopped, the phlegm, continuing to arise, must render the spirit continually weaker and weaker. The distillation therefore ought to be discontinued at this period, or rather while some of the salt still remains undissolved; the spirit will thus prove always equal, and the buyers be furnished with a certain criterion of its strength. Very few have taken any notice of the abovementioned inconvenience of these kinds of spirits; and the remedy is first hinted at in the *Pharmacopœia Reformata*. The purity of the spirit is easily determined from its clearness and grateful odour.

Volatile alkaline salts, and their solutions called *spirits*, agree in many respects with fixed alkalis, and their solutions or leys; as in changing the colour of blue flowers to a green; effervescing, when in their mild state, with and neutralizing acids: liquefying the animal juices; and corroding the fleshy parts, so as, when applied to the skin, and prevented from exhaling by a proper covering, to act as caustics; dissolving oils and sulphur, though less readily than the fixed alkalis, on account probably of their not being able to bear any considerable heat, by which their activity might be promoted. Their principle difference from the other alkalis seems to consist in their volatility. They exhale or emit pungent vapours in the coldest state of the atmosphere; and by their stimulating smell they prove serviceable in languors and faintings. Taken internally, they discover a greater colliquating as well as stimulating power: the blood drawn from a
veins

tions.

vein after their use has been continued for some time, is said to be remarkably more fluid than before; they are likewise more disposed to operate by perspiration, and to act on the nervous system. They are particularly useful in lethargic cases; in hysterical and hypochondriacal disorders; and in the languors, headachs, inflations of the stomach, flatulent colics, and other symptoms which attend them. They are generally found more serviceable to aged persons, and in phlegmatic habits, than in the opposite circumstances. In some fevers, particularly those of the low kind, accompanied with a cough, hoarseness, and a redundancy of phlegm, they are of great utility, raising the *vis vitalis*, and exciting a salutary diaphoresis; but in putrid fevers, scurvy, and wherever the mass of blood is thin and acrimonious, their use is ambiguous. As they are more powerful than the fixed in liquefying tenacious humours, so they prove more hurtful where the fluids are already in a colliquated state. In vernal intermittents, particularly those of the slow kind, they are often the most efficacious remedy. Dr Bisset observes, in his Essay on the Medical Constitution of Great Britain, that though many cases occur which will yield to no other medicine than the bark, yet he has met with many which were only suppressed from time to time by the bark, but were completely cured by alkaline spirits. He tells us, that these spirits will often carry off vernal intermittents without any previous evacuation: but that they are generally more effectual if a purge be premised; and in plethoric or inflammatory cases, or where the fever personates a remittent, venesection is necessary.

These salts are most commodiously taken in a liquid form, largely diluted: or in that of a bolus, which should be made up only as it is wanted. The dose is from a grain or two to ten or twelve. Ten drops of a well made spirit, or saturated solution, are reckoned to contain about a grain of the salt. In intermittents, 15 or 20 drops of the spirit are given in a tea-cupful of cold spring water, and repeated five or six times in each intermission.

The volatile salts and spirits prepared from different animal substances, have been supposed capable of producing different effects on the human body, and to receive specific virtues from the subject. The salt of vipers has been esteemed particularly serviceable in disorders occasioned by the bite of that animal; and a salt drawn from the human skull, in diseases of the head. But modern practice acknowledges no such different effects from these preparations; and chemical experiments have shown their identity. There is indeed when not sufficiently purified, a very perceptible difference in the smell, taste, degree of pungency, and volatility of these salts; and in this state their medicinal virtues vary considerable enough to deserve notice: but this difference they have in common, according as they are more or less loaded with oil, not as they are produced from this or that animal substance. At first distilled, they may be looked on as a kind of volatile soap, in which the oil is the prevailing principle; in this state they have much less of the proper alkaline acrimony and pungency than when they have undergone repeated distillations, and such other operations as disengage the oil from the salt; for by those means they lose their saponaceous quality,

and acquiring greater degrees of acrimony, become medicines of a different class. These preparations therefore do not differ near so much from each other, as they do from themselves in different states of purity. To which may be added, that when we consider them as loaded with oil, the virtues of a distilled animal oil itself are likewise to be brought into the account.

These oils, as first distilled, are highly fetid and offensive, of an extremely heating quality, and of such activity, that, according to Hoilman's account, half a drop dissolved in a dram of spirit of wine is sufficient to raise a copious sweat. By repeated rectification, they lose their offensiveness, and at the same time become mild in their medicinal operation. The rectified oils may be given to the quantity of twenty or thirty drops, and are said to be anodyne and antispasmodic, to procure a calm sleep and gentle sweat, without heating or agitating the body, as has been observed in treating of the animal oil. It is obvious, therefore, that the salts and spirits must differ, not only according to the quantity of oil they contain, but according to the quality of the oil itself in its different states.

The volatile salt and spirits, as first distilled, are of a brown colour, and a very offensive smell; by repeated rectification, as directed in the processes above set down, they lose great part of the oil on which these qualities depend, the salt becomes white, the spirit limpid as water, and of a grateful odour; and this is the mark of sufficient rectification.

It has been objected to the repeated rectification of these preparations, that, by separating the oil, it renders them similar to the pure salt and spirit of sal ammoniac, which are procurable at an easier rate. But the intention is not to purify them wholly from the oil, but to separate the grosser part, and to subtilize the rest, so as to bring it towards the same state as when the oil is rectified by itself. The rectification of spirit of hartshorn has been repeated twenty times successively, and found still to participate of oil, but of an oil very different from what it was in the first distillation.

The rectified oils, in long-keeping, become again fetid. The salt and spirits also, however carefully rectified, suffer in length of time the same change; restoring their original brown colour and ill smell; a proof that the rectification is far from having divested them of oil. Any intentions however, which they are thus capable of answering, may be as effectually accomplished by a mixture of the volatile alkali with the animal oil, in its rectified state, to any extent that may be thought necessary.

Vitriolat. d. kali. L.

Take of the salt which remains after the distillation of the nitrous acid, two pounds. Distilled water, two gallons. Burn out the superfluous acid with a strong fire in an open vessel: then boil it a little white in the water; strain and set the liquor aside to crystallize.

The salt thus formed is the same with the vitriolated tartar of the last edition of the London pharmacopœia; but it is now prepared in a cheaper and easier manner, at least for those who distil the nitrous acid. In both ways a neutral is formed, consisting of the fixed vegetable

Preparations and Compositions.

table alkali, united to the vitriolic acid. But a similar compound may also be obtained by the following process of the Edinburgh pharmacopœia.

Vitriolated fixed vegetable alkali, commonly called *vitriolated tartar*. E.

- 229 Take of vitriolic acid, diluted with six times its weight of water, as much as you please. Put it into a capacious glass vessel, and gradually drop into it, of purified fixed vegetable alkali, diluted with six times its weight of water, as much as is sufficient thoroughly to neutralize the acid. The effervescence being finished, strain the liquor through paper; and after proper evaporation, set it aside to crystallize.

The operator ought to take care that the vapour separated during the effervescence shall not be applied to his nostrils; as fixed air, when applied to the olfactory nerves, is highly deleterious to life.

This is an elegant and one of the least troublesome ways of preparing this salt. The Edinburgh college, in their former editions, ordered the acid liquor to be dropped into the alkali; by the converse procedure now received, it is obviously more easy to secure against a redundance of acidity: and for the greater certainty in this point it may be expedient, as in the foregoing process, to drop in a little more of the alkaline ley than the cessation of the effervescence seems to require.

In a former edition of the same pharmacopœia, the acid was directed to be diluted only with its equal weight of water, and the alkali with that quantity of water which it is capable of imbibing from the atmosphere. By that imperfection there was not water enough to keep the vitriolated tartar dissolved; on which account, as fast as the alkali was neutralized by the acid, a great part fell to the bottom in a powdery form. In order to obtain perfect and well formed crystals, the liquor should not be set in the cold, but continued in moderate heat, such as the hand can scarcely bear, that the water may slowly evaporate.

It is remarkable, that although the vitriolic acid and fixed alkaline salt do each readily unite with water, and strongly attract moisture, even from the air, yet the neutral resulting from the combination of these two, vitriolated tartar, is one of the salts most difficult of solution, very little of it being taken up by cold water.

Vitriolated tartar, in small doses, as a scruple or half a dram, is an useful aperient; in large ones, as four or five drams, a mild cathartic, which does not pass off so hastily as the bitter cathartic sal or salt of Glauber, and seems to extend its action further. The wholesale dealers in medicines have commonly substituted for it an article otherwise almost useless in their shops, the residuum of Glauber's spirit of nitre. This may be looked on as a venal fraud, if the spirit has been prepared as formerly directed, and the residuum dissolved and crystallized: but it is a very dangerous one if the vitriolic acid has been used in an over proportion, and the caput mortuum employed without crystallization; the salt in this case, instead of a mild neutral one, of a moderately bitter taste, proving highly acid. The purchaser ought therefore to insist on the salt being in

Preparations and Compositions.

a crystalline form. The crystals when perfect are oblong, with six flat sides, and terminated at each end by a six-sided pyramid; some appear composed of two pyramids joined together by the bases; and many, in the most perfect crystallizations we have seen, are very irregular. They decrepitate in the fire, somewhat like those of sea-salt, for which they have sometimes been mistaken.

Salt of many virtues. E.

Take nitre in powder, flowers of sulphur, of each equal parts. Mix them well together, and inject the mixture by little and little at a time into a red-hot crucible: the deslagration being over, let the salt cool, after which it is to be put up in a glass vessel well shut. The salt may be purified by dissolving it in warm water, filtering the solution, and exhaling it to dryness, or by crystallization.

This is another method of uniting the vitriolic acid with the common vegetable fixed alkali. Both the nitre and the sulphur are decomposed in the operation: the acid of the nitre, and the inflammable principle of the sulphur, detonate together, and are dissipated; while the acid of the sulphur, (which, as we have already seen, is no other than the vitriolic acid) remains combined with the alkaline basis of the nitre. The shops accordingly have substituted the foregoing preparation for the sal pochirest.

Vitriolated natron. L.

Take of the salt which remains after the distillation of the muriatic acid, two pounds; distilled water, two pints and an half. Burn out the superfluous acid with a strong fire in an open vessel; then boil it for a little in the water; strain the solution, and set it by to crystallize.

Vitriolated soda, commonly called *cathartic salt of Glauber*. E.

Dissolve in warm water the mass which remains after the distillation of spirit of sea-salt: filtre the solution, and crystallize the salt.

The directions given for the preparation of this salt, long known by the name of *sal mirabile Glauberi*, are nearly the same in the pharmacopœias of both colleges; but those of the London college are to be preferred, as being most accurate and explicit.

In a former edition of the Edinburgh pharmacopœia, it was ordered, that if the crystals (obtained as above) proved too sharp, they should again be dissolved in water, and the filtered liquor evaporated to such a pitch only as may dispose the salt to crystallize. But there is no great danger of the crystals proving too sharp, even when the spirit of salt is made with the largest proportion of oil of vitriol directed under that process. The liquor which remains after the crystallization is indeed very acid; and with regard to this preparation, it is convenient it should be so; for otherwise the crystals will be very small, and likewise in a small quantity. Where a sufficient proportion of oil of vitriol has not been employed in the distillation of the spirit, it is necessary to add some to the liquor, in order to promote crystallization of the salt.

The title of *cathartic salt*, which this salt has often had, expresses its medical virtues. Taken from half

230

231

232

an

Preparations and Compositions

an ounce to an ounce, or more, it proves a mild and useful purgative; and in smaller doses, largely diluted, a serviceable aperient and diuretic. The shops frequently substitute for it the bitter cathartic salt, which is nearly of the same quality, but somewhat more unpleasent, and, as is said, less mild in operation. They are very easily distinguishable from each other, by the effect of alkaline salts upon solutions of them. The solutions of Glauber's salt suffer no visible change from this addition, its own basis being a true fixed alkali: but the solution of the bitter cathartic salt grows instantly white and turbid; its basis, which is an earth, being extricated copiously by the alkaline salt.

Purified nitre. L.

233 Take of nitre two pounds; distilled water, four pints.

Boil the nitre in the water till it be dissolved; strain the solution, and set it aside to crystallize.

Common nitre contains usually a considerable portion of a sea-salt, which in this process is separated, the sea-salt remaining dissolved after the greatest part of the nitre has crystallized. The crystals which shoot after the first evaporation are large, regular, and pure: but when the remaining liquor is further evaporated, and this repeated a second or third time, the crystals prove at length small, imperfect, and tipped with little cubical crystals of sea-salt.

When rough nitre, in the state wherein it is first extracted from the earths impregnated with it, is treated in this manner, there remains at last a liquor called *mother-ley*, which will no longer afford any crystals. This appears to participate of the nitrous and marine acids, and to contain an earthy matter dissolved by these acids. On adding alkaline lixivium, the earth is precipitated; and when thoroughly washed with water, proves insipid. If the liquor be evaporated to dryness, a bitterish saline matter is left; which being strongly calcined in a crucible, parts with the acids, and becomes, as in the other case, insipid.

This earth has been celebrated as an excellent purgative, in the dose of a dram or two: and in smaller doses, as an alterant in hypochondriacal and other disorders. This medicine was for some time kept a great secret, under the name of *magnesia alba, nitrous panacea, Count Palma's powder, il polvere allo Romano, poudre de Sentinelli*, &c. till Lancisi made it public in his notes on the *Metallotheca Vaticana*. It has been supposed, that this earth is no other than a portion of the lime commonly added in the elixation of the nitre at the European nitre works: but though the specimens of magnesia examined by Neumann, and some of that which has lately been brought hither from abroad, gave plain marks of a calcareous nature; yet the true magnesia must be an earth of a different kind, calcareous earths being rather astrigent than purgative. The earthy basis of the bitter cathartic salt is found to have the properties ascribed to the true magnesia of nitre, and appears to be the very same species of earth: from that salt therefore this medicine is now prepared, as will be seen hereafter. The magnesia alba differs from calcareous earths, in having a less powerful attraction for fixed air, and in not becoming caustic by calcination.

VOL. XIV.

Acetated kali. L.

Take of kali one pound; boil it with a slow fire in four or five times its quantity of distilled vinegar; the effervescence ceasing, let there be added at different times more distilled vinegar, until the last vinegar being nearly evaporated, the addition of fresh will excite no effervescence, which will happen when about twenty pounds of distilled vinegar are consumed: afterwards let it be dried slowly. An impure salt will be left, which melts for a little while with a slow fire; then let it be dissolved in water, and filtered through paper. If the fusion has been rightly performed, the strained liquor will be colourless; if otherwise, of a brown colour. Lastly, evaporate this liquor, with a slow fire, in a very shallow glass vessel; frequently stirring the mass, that the salt may be more completely dried, which should be kept in a vessel close stopped. The salt ought to be very white, and dissolve wholly, both in water and spirit of wine, without leaving any feces. If the salt although white, should deposit any feces in spirit of wine, that solution in the spirit should be filtered through paper, and the salt again dried.

Acetated fixed vegetable alkali, commonly called regenerated tartar. E.

235 Take of salt of tartar one pound; boil it with a very gentle heat in four or five times its quantity of distilled vinegar; add more distilled vinegar at different times, till on the watery part of the former quantity being nearly dissipated by evaporation, the new addition of vinegar ceases to raise any effervescence. This happens when about twenty pounds by weight of distilled vinegar has been consumed. The impure salt remaining after the exsiccation, is to be liquefied with a gentle heat for a short time, and it is proper that it should only be for a short time; then dissolve it in water, and strain through paper. If the liquefaction has been properly performed the strained liquor will be limpid, but if otherwise, of a brown colour. Evaporate this liquor with a very gentle heat in a shallow glass vessel, occasionally stirring the salt as it becomes dry, that its moisture may sooner be dissipated. Then put it up into a vessel very closely stopped, to prevent it from liquefying in the air.

This salt had formerly the name of *diuretic salt* in the London pharmacopœia; but that which they now employ, or perhaps in preference to it, the name of *potassa acetata*, gives a clearer idea of its nature.

The purification of this salt is not a little troublesome. The operator must be particularly careful, in melting it, not to use a great heat, or to keep it long liquefied: a little should be occasionally taken out, and put into water; and as soon as it begins to part freely with its black colour, the whole is to be removed from the fire. In the last drying, the heat must not be so great as to melt it; otherwise it will not prove totally soluble. If the solution in spirit of wine be exsiccated, and the remaining salt liquefied with a very gentle fire, it gains the leamy appearance which has procured it the name *terra foliata*.

X x

In

In the fourth volume of the Memoirs of the correspondents of the French Academy, lately published, Mr Cadet has given a method of making the salt white at the first evaporation, without the trouble of any farther purification. He observes that the brown colour depends on the oily matter of the vinegar being burnt by the heat commonly employed in the evaporation: and his improvement consists in diminishing the heat at the time that this burning is liable to happen. The process he recommends is as follows:

Dissolve a pound of salt of tartar in a sufficient quantity of cold water; filter the solution, and add by degrees as much distilled vinegar as will saturate it, or a little more. Set the liquor to evaporate in a stone-ware vessel in a gentle heat, not so strong as to make it boil. When a pellicle appears on the surface, the rest of the process must be finished in a water-bath. The liquor acquires by degrees an oily consistence, and a pretty deep brown colour; but the pellicle or scum on the top looks whitish, and when taken off and cooled, appears a congeries of little brilliant silver-like plates. The matter is to be kept continually stirring, till it be wholly changed into this white flaky matter; the complete drying of which is most conveniently effected in a warm oven.

We shall not take upon us to determine whether the pure or impure salt is preferable as a medicine; observing only, that the latter is more of a saporaceous nature, the former more acrid, though somewhat more agreeable to the stomach. Mr Cadet reckons the salt prepared in his method superior both to the brown and white sorts made in the common way, as possessing both the oily quality of the one and the agreeableness of the other, and as being always uniform or of the same power: whereas the others are liable to vary considerably, according to the degree of heat employed in the evaporation. They are all medicines of great efficacy, and may be so dosed and managed as to prove either mildly cathartic, or powerfully diuretic; few of the saline deobstruents come up to them in virtue. The dose is from half a scruple to a dram or two. A bare mixture, however, of alkaline salt and vinegar, with exsiccation, is not perhaps much inferior as a medicine to the more elaborate salt. Two drams of the alkali, saturated with vinegar, have been known to occasion ten or twelve stools in hydroptic cases, and a plentiful discharge of urine, without any inconvenience.

Water of acetated ammonia. L.

- 236 Take of ammonia, by weight, two ounces; distilled vinegar, four pints; or as much as is sufficient to saturate the ammonia. Mix.

Spirit of Mindereri. E.

- 237 Take any quantity of the volatile alkaline salt of sal ammoniac, and gradually pour upon it distilled vinegar till the effervescence ceases; occasionally stirring the mixture to promote the action of the vinegar on the salt.

Though this article has long been known by the name of Spiritus Mindereri, so called from the inventor; yet that employed by the London college is undoubtedly preferable, as giving a proper idea of its constituent parts.

This is an excellent aperient saline liquor. Taken warm in bed, it proves commonly a powerful diaphoretic or sudorific; and as it operates without heat, it has place in febrile and inflammatory disorders, where medicines of the warm kind, if they fail of procuring sweat, aggravate the distemper. Its action may likewise be determined to the kidneys, by walking about in a cool air. The common dose is half an ounce, either by itself, or along with other medicines adapted to the intention. Its strength is not a little precarious, depending much on that of the vinegar: an inconvenience which cannot easily be obviated, for the saline matter is not reducible to the form of a concrete salt.

Tartarized kali. L.

Take of kali one pound; crystals of tartar, three pounds; distilled water, boiling, one gallon. To the salt, dissolved in water, throw in gradually the crystals of tartar, powdered; filter the liquor, when cold, through paper: and, after due evaporation, set it apart to crystallize. 238

Tartarized vegetable fixed alkali, commonly called soluble tartar. E.

Take of purified fixed vegetable alkaline salt one pound; water, 15 pounds. To the salt dissolved in the boiling water gradually add crystals of tartar in fine powder, as long as the addition thereof raises any effervescence, which almost ceases before three times the weight of the alkaline salt hath been injected; then strain the cooled liquor through paper, and after due evaporation set it aside to crystallize. 239

Common white tartar is perhaps preferable for this operation to the crystals usually met with. Its impurities can here be no objection; since it will be sufficiently depurated by the subsequent filtration.

The preparation of this medicine by either of the above methods is very easy; though some chemists have rendered it sufficiently troublesome, by a nicety which is not at all wanted. They insist upon hitting the very exact point of saturation between the alkaline salt and the acid of the tartar; and caution the operator to be extremely careful, when he comes near this mark, lest by imprudently adding too large a portion of either, he render the salt too acid or too alkaline. If the liquor be suffered to cool a little before it be committed to the filter, and then properly exhaled and crystallized, no error of this kind can happen, though the saturation should not be very exactly hit; for since crystals of tartar are very difficultly soluble even in boiling water, and when dissolved therein concrete again upon the liquor's growing cold, if any more of them has been employed than is taken up by the alkali, this superfluous quantity will be left upon the filter; and, on the other hand, when too much of the alkali has been used, it will remain uncrystallized. The crystallization of this salt indeed cannot be effected without a good deal of trouble: it is therefore most convenient to let the acid salt prevail at first; to separate the superfluous quantity, by suffering the liquor to cool a little before filtration; and then proceed to the total evaporation of the aqueous fluid, which will leave behind it the neutral salt required. The most proper vessel for this purpose is a stone-ware one; iron discolours the salt.

Soluble

Prepara-
tions and
Composi-
tions.

Soluble tartar, in doses of a scruple, half a dram, or a dram, is a mild cooling aperient: two or three drams commonly loosen the belly; and an ounce proves prettily strongly purgative. It has been particularly recommended as a purgative for maniacal and melancholic patients. Malouin says, it is equal in purgative virtue to the cathartic salt of Glauber. It is an useful addition to the purgatives of the resinous kind, as it promotes their operation, and at the same time tends to correct their griping quality. But it must never be given in conjunction with any acid; for all acids decompose it, absorbing its alkaline salt, and precipitating the tartar. On this account it is improper to join it to tamarinds, or such like acid fruits; which is too often done in the extemporaneous practice of those physicians who are fond of mixing different cathartics together.

Tartarized natron. L.

- 240 Take of natron, 20 ounces; crystals of tartar, powdered, 2 pounds; distilled water, boiling, 10 pints. Dissolve the natron in the water, and gradually add the crystals of tartar: filter the liquor through paper: evaporate and set it aside to crystallize.

Tartarized soda, commonly called *Rochel salt.* E.

- 241 The Rochel salt may be prepared from purified fossil alkaline salt and crystals of tartar, in the same manner as directed for the soluble tartar.

This is a species of soluble tartar, made with the salt of kali or soda, which is the same with the mineral alkali, or basis of sea salt. It crystallizes far more easily than the preceding preparation, and does not, like it, grow moist in the air. It is also considerably less purgative, but is equally decomposed by acids. It appears to be a very elegant salt, and begins now to come into esteem in this country, as it has long been in France.

Purification of alum. L.

- 242 Take of alum, one pound; chalk one dram by weight; distilled water, one pint. Boil them a little, strain, and set the liquor aside to crystallize.

We have already offered some observations on alum (see ALUM); and in general we may say that it comes from the alum works in England in a state of such purity as to be fit for every purpose in medicine; accordingly we do not observe that the purification of alum has a place in any other pharmacopœias; but by the present process it will be freed, not only from different impurities, but also from superabundant acid.

Burnt alum. L. E.

- 243 Take of alum, half a pound. Burn it in an earthen vessel so long as it bubbles.

This, with strict propriety, ought rather perhaps to be called dried alum than burnt alum: for the only effect of the burning here directed is to expel the water. In this state it is so acrid as to be frequently employed as an escharotic; and it is with this intention chiefly that it has a place in our pharmacopœias: but it has sometimes also been taken internally, particularly in cases of cholera.

Salt or sugar of milk. Succ.

- 244 Take of the whey of milk, prepared by runnet, any

quantity; let it be boiled over a moderate fire to the consistence of a syrup; then put it in a cold place, that crystals may be formed. Let the fluid which remains be again managed in the same manner, and let the crystals formed be washed with cold water.

It has been by some imagined, that the superiority of one milk over another depends on its containing a larger proportion of this saline or saccharine part; and particularly that upon this the reputed virtues of ass milk depend. Hence this preparation has been greatly celebrated in disorders of the breast, but it is far from answering what has been expected from it. It has little sweetness, and is difficult of solution in water. A saline substance, much better deserving the name of sugar, may be obtained by evaporating new milk, particularly that of the ass, to dryness, digesting the dry matter in water till the water has extracted its soluble parts, and then inspissating the filtered liquor. This preparation is of great sweetness, though neither white nor crystalline; nor is it perhaps in the pure crystallizable parts of milk that its medicinal virtues reside; and so little reliance is put on it as a medicine, that it has no place in the London or Edinburgh pharmacopœias; although it long has stood, and still stands, in the foreign ones.

Salt of ferrel. Succ.

Take any quantity of the expressed juice of the leaves of wood ferrel; let it boil gently, that the feculent matter may be separated; then strain it till it be clear, and after this boil it on a moderate fire to the consistence of a syrup. Put it into long-necked glass vessels, and place it in a cold situation that it may crystallize. Let these crystals be dissolved in water, and again formed into purer ones.

To make the ferrel yield its juice readily, it should be cut to pieces, and well bruised in a small mortar, before it be committed to the press. The magma which remains in the bag still retaining no inconsiderable quantity of saline matter, may be advantageously boiled in water, and the decoction added to the expressed juice. The whole may be afterwards depurated together, either by the method above directed, or by running the liquor several times through a linen cloth. In some cases the addition of a considerable portion of water is necessary, that the juice, thus diluted may part the more freely with its feculencies; on the separation of which the success of the process much depends.

The evaporation should be performed either in shallow glass basons, or in such earthen ones as are of a compact close texture; such are those usually called *stone ware*. The common earthen vessels are subject to have their glazing corroded, and are so extremely porous, as readily to imbibe and retain a good quantity of the liquor; metallic vessels are particularly apt to be corroded by these acid kinds of juices.

These juices are so viscid, and abound so much with heterogeneous matter, of a quite different nature from any thing saline, that a pellicle, or pure saline incrustation upon the surface, is in vain expected. Boerhaave, therefore, and the more expert writers in pharmaceutical chemistry, with great judgment direct the evaporation of the superfluous moisture to be continued

until the matter has acquired the consistence of cream. If it be now suffered to stand for an hour or two in a warm place, it will, notwithstanding the former depositions, deposit a fresh sediment, from which it should be warily decanted before it be put into the vessel in which it is designed to be crystallized.

Some recommend an unglazed earthen vessel as preferable for this purpose to a glass one; the smoothness of the latter being supposed to hinder the salt from sticking thereto; while the juice easily insinuating itself into the pores of the former, has a great advantage of shooting its saline spicula to the sides. Others slightly incrustate the sides and bottom of whatever vessel they employ with a certain mineral salt, which greatly disposes the juice to crystallize, to which of itself it is very averse; but this addition is, with regard to its medical virtue, quite different from the salt here intended.

The liquor which remains after the crystallization may be separated by a gentle colature, and after due inspissation set to shoot again; when a farther produce of crystals will be obtained.

The process for obtaining this salt is very tedious; and the quantity of salt which the juices afford is extremely small: hence they are hardly ever made or expected in the shops. They may be somewhat sooner separated from the mucilage and other feculencies, by clarification with whites of eggs, and by adding very pure white clay.

In the manner above described, salts may also be obtained from other acid, austere, and bitterish plants, which contain but a small quantity of oil.

The virtues of the essential salts have not been sufficiently determined from experience. This much, however, is certain, that they do not, as has been supposed, possess the virtues of the subjects entire, excepting only the acids and sweets. The others seem to be almost all of them nearly similar, whatever plant they were obtained from. In watery extracts of wormwood, carduus, camomile, and many other vegetables, kept for some time in a soft state, there may be observed fine saline efflorescences on the surface, which have all nearly the same taste, somewhat of the nitrous kind. They are supposed by some to be in reality no more than an impure species of volatile nitre (that is, a salt composed of the nitrous acid and volatile alkali): those which were examined by the chemists of the French academy desfligrated in the fire, and being triturated with fixed alkali, exhale an urinous odour; plain marks of their containing those two ingredients.

Acid salt of borax. Succ.

246

Take of borax an ounce and a half; warm spring-water, one pound. Mix them in a glass vessel, that the borax may be dissolved; then pour into it three drams of the concentrated acid of vitriol: evaporate the liquor till a pellicle appears upon it; after this let it remain at rest till the crystals be formed. Let them be washed with cold water, and kept for use.

This salt, which has long been known by the title of the *sedative salt of Homburg*, is not unfrequently formed by sublimation: but the process by crystallization here directed is less troublesome, though the salt proves generally less white, and is apt likewise to

tain a part of Glauber's salt, especially if the evaporation be long protracted.

The salt of borax to the taste appears to be a neutral; but when it is examined by alkalis, it shows the properties of an acid, effervescing, uniting, and crystallizing with them, and it destroys their alkaline quality. It dissolves both in water and spirit of wine, although not very readily in either.

The virtues attributed to it may in some degree be inferred from the name of *sedative*, by which it was long distinguished. It has been supposed to be a mild anodyne, to diminish febrile heat, to prevent or remove delirium, and to allay, at least for some time, spasmodical affections, particularly those which are the attendants of hypochondriasis and hysteria. It may be given in doses from two to twenty grains.

Purified sal ammoniac. Succ.

Dissolve sal ammoniac in spring water; strain the liquor through paper, evaporate it to dryness in a glass vessel by means of a moderate fire.

The sal ammoniac imported from the Mediterranean often contains such impurities as to render the above process necessary; but that which is prepared in Britain from foot and sea salt, is in general brought to market in a state of very great purity. Hence this process is now altogether omitted both in the London and Edinburgh Pharmacopœias. It furnishes, however, when necessary, an easy and effectual mode of obtaining a pure ammonia muriata.

247

CHAP VIII. *Magnesia.*

White magnesia.

Take of bitter purging salt, kali, each two pounds; distilled water, boiling, 20 pints. Dissolve the bitter salt and the kali separately in 10 pints of water, and filter through paper: then mix them. Boil the liquor a little while, and strain it while hot through linen, upon which will remain the white magnesia; then wash away, by repeated affusions of distilled water, the vitriolated kali. *L.*

248

Take of bitter purging salt, and purified fixed vegetable alkali, equal weights. Dissolve them separately in double their quantity of warm water, and let the liquor be strained or otherwise freed from the feces; then mix them, and instantly add eight times their quantity of warm water. Let the liquor boil a little, stirring it very well at the same time: then let it rest till the heat be somewhat diminished; after which strain it through a cloth: the magnesia will remain upon the cloth, and it is to be washed with pure water till it be altogether void of saline taste. *E.*

The processes here directed by the London and Edinburgh colleges are nearly the same; but the former seem to have improved somewhat on the latter, both in simplifying the process, and in the employment of distilled water.

The *bitter cathartic salt*, or *Epsom salt*, is a combination of the vitriolic acid and magnesia. In this process, then, a double elective attraction takes place: the vitriolic

Prepara-
tions and
Composi-
tions.

vitriolic acid forsakes the magnesia, and joins the mild alkali, for which it has a greater attraction; while the magnesia in its turn unites with the fixed air discharged from the mild alkali, and ready to be absorbed by any substance with which it can combine.

We have therefore two new products, viz. a vitriolated tartar, and magnesia united with fixed air. The former is dissolved in the water, and may be preserved for use; the latter, as being much less soluble, sinks to the bottom of the vessel. The intention of employing such a large quantity of water and of the boiling is, that the vitriolated tartar may be all thoroughly dissolved; this salt being so scarcely soluble in water, that without this expedient a part of it might be precipitated along with the magnesia. It might perhaps be more convenient to employ the mineral alkali; which forming a Glauber's salt with the vitriolic acid, would require less water for its suspension. By the after ablutions, however, the magnesia is sufficiently freed from any portion of vitriolated tartar which may have adhered to it.

The ablutions should be made with very pure water; for nicer purposes distilled water may be used with advantage; and soft water is in every case necessary. Hard water for this process is peculiarly inadmissible, as the principle in waters giving the property called *hardness* is generally owing to an imperfect nitrous selenite, whose base is capable of being disengaged by magnesia united with fixed air. For though the attraction of magnesia itself to the nitrous acid is not greater than that of calcareous earths; yet when combined with fixed air, a peculiar circumstance intervenes; whence it is deducible, that the sum of the forces tending to join the calcareous earth with the air of the magnesia, and the magnesia with the acid, is greater than the sum of the forces tending to join the calcareous earth with the acid, and the magnesia with the fixed air.

This phenomenon must therefore depend on the presence of fixed air, and its greater attraction for lime than for magnesia. On this account, if hard water be used, a quantity of calcareous earth must infallibly be deposited on the magnesia; while the nitrous acid with which it was combined in the water, will in its turn attach itself to a portion of the magnesia, forming what may be called a *nitrous magnesia*.

All the alkalis, and also calcareous earths, have a greater attraction for fixed air than magnesia has: Hence, if this last be precipitated from its solution in acids by caustic alkali, it is then procured free from fixed air: but for this purpose calcination is more generally employed in the manner described in the process which next follows. Magnesia is scarcely at all soluble in water: the infinitely small portion which this fluid is capable of taking up, is owing to the fixed air of the magnesia; and it has been lately discovered, that water impregnated with this acid is capable of dissolving a considerable portion; for this purpose it is necessary to employ magnesia already saturated with fixed air, as magnesia deprived of this air would quickly abstract it from the water, whereby the force of the latter would be very considerably diminished. Such a solution of magnesia might be useful for several purposes in medicine.

Prepara-
tions and
Composi-
tions.

Magnesia is the same species of earth with that obtained from the mother-ley of nitre, which was for several years a celebrated secret in the hands of some particular persons abroad. Hoffman, who describes the preparations of the nitrous magnesia, gives it the character of an useful antacid, a safe and inoffensive laxative in doses of a dram or two, and a diaphoretic and diuretic when given in smaller doses of 15 or 20 grains. Since his time, it has had a considerable place in the practice of foreign physicians; and is now in great esteem among us, particularly in heart-burns, and for preventing or removing the many disorders which children are so frequently thrown into from a redundancy of acid humours in the first passages; it is preferred, on account of its laxative quality, to the common absorbents, which, unless gentle purgatives be occasionally given to carry them off, are apt to lodge in the body, and occasion a cohesiveness very detrimental to infants.

Magnesia alba, when prepared in perfection, is a white and very subtle earth, perfectly void of smell or taste, of the class of those which dissolve in acids. It dissolves freely even in the vitriolic acid; which, in the common way of making solutions, take up only an inconsiderable portion of other earths. Combined with this acid, it forms the bitter purging or Epsom salt, very easily soluble in water: while the common absorbents form with the same acid almost insipid concretions, very difficult of solution. Solutions of magnesia in all acids are bitter and purgative, while those of the other earths are more or less astringent and astringent. A large dose of magnesia, if the stomach contain no acid to dissolve it, does not purge or produce any sensible effect; a moderate one, if an acid be lodged there, or if acid liquors be taken after it, procures several stools; whereas the common absorbents, in the same circumstances, instead of loosening, bind the belly. It is obvious, therefore, that magnesia is specifically different from the other earths, and that it is applicable to several useful purposes in medicine.

Magnesia was formerly made with the mother-water of nitre evaporated to dryness, or precipitated by a fixed alkali. It has gone under different names, as the *white Powder of the Count of Palma*, *powder of sentinelle*, *psychrest*, *laxative powder*, &c. It seems to have got the character *white*, to distinguish it from the dark coloured mineral called also *magnesia* or *manyanse*; a substance possessing very different properties. We have not heard that pure native magnesia has been found in its uncombined state. A combination of it with sulphur has been discovered to cover a stratum of coal at Littry in Lower Normandy. It has also been found in certain serpentine earths in Saxony, and in marly and alum earths.

Calined magnesia.

Take of white magnesia, four ounces. Expose it to a strong heat for two hours; and, when cold, set it by. Keep it in a vessel closely stopped. *L.*

Let magnesia, put into a crucible, be continued in a red heat for two hours; then put it up in close glass vessels. *E.*

By this process the magnesia is freed of fixed air; which, according to Dr Black's experiments, contrib-

tutes about $\frac{1}{7}$ ths of its weight. A kind of opaque foggy vapour is observed to escape during the calcination, which is nothing else than a quantity of fine particles of magnesia buoyed off along with a stream of the disengaged air. About the end of the operation, the magnesia exhibits a kind of luminous or phosphorescent property; and this may be considered as a pretty exact criterion of its being deprived of air.

Calcined magnesia is equally mild as when saturated with fixed air; and this circumstance is sufficient to establish a difference between it and calcareous earths, all of which are converted by calcination into caustic quicklime.

The calcined magnesia is used for the same general purposes as the magnesia combined with fixed air. In certain affections of the stomach, accompanied with much flatulance, the calcined magnesia is found preferable, not only as containing more of the real earth of magnesia in a given quantity, but as being also deprived of its air. It neutralizes the acid of the stomach without that extirpation of air which is often a troublesome consequence in employing the aerated magnesia in these complaints. It is proper to observe, that magnesia, whether combined with or deprived of fixed air, is similar to the mild calcareous earths in promoting and increasing putrefaction. The same has even been observed with respect to the Epsom and some other salts which have this earth for their base.

CHAP. IX. Preparations of Sulphur.

Washed flowers of Sulphur. L.

550 Take of flowers of sulphur, one pound; distilled water, four pints. Boil the flowers of sulphur a little while in the distilled water; then pour off this water, and wash off the acid with cold water; lastly, dry the flowers.

In the former editions of our pharmacopœias directions were given for the preparation of the flowers of sulphur themselves; but as a large apparatus is necessary for doing it with any advantage, it is now scarcely ever attempted by the apothecaries. When the flowers are properly prepared, no change is made on the qualities of the sulphur. Its impurities only are separated; and at the same time it is reduced to a finer powder than it can easily be brought to by any other means. But as the flowers of sulphur are generally sublimed in very capacious rooms, which contain a large quantity of air, or in vessels not perfectly close, some of those that arise at first are apt to take fire, and thus are changed into a volatile acid vapour, which mingling with the flowers that sublime afterwards, communicates to them a considerable degree of acidity. In this case the ablution here directed is for the general use of the medicine absolutely necessary; for the flowers thus tainted with acid sometimes occasion gripes, and may in other respects be productive of effects different from those of pure sulphur. There are, however, some particular combinations to which they are supposed to be better adapted when unwashed, such as their union with mercury into æthiops mineral; and accordingly for that preparation the unwashed flowers are directed by the London college.

Sulphurated kali. L.

Take of flowers of sulphur, one ounce; kali, five ounces. Mix the salt with the melted sulphur, by frequently stirring, until they unite into an uniform mass.

This preparation, in the former editions of our pharmacopœias, had the name of *hepar sulphuris* or *liver of sulphur*.

It is much more convenient to melt the sulphur first by itself, and add the salt of tartar by degrees, as here directed, than to grind them together, and afterwards endeavour to melt them, as ordered in former editions; for in this last case the mixture will not flow sufficiently thin to be properly united by stirring; and the sulphur either takes fire or sublimes in flowers, which probably has been the reason why so large a proportion of it has been commonly directed. Even in the present method a considerable part of the sulphur will be dissipated; and if it were not, the hepar would not be of its due quality: for one part of sulphur requires two of the alkaline salt to render it perfectly soluble in water, which this preparation ought to be.

The hepar sulphuris has a fetid smell and a nauseous taste. Solutions of it in water, made with sugar into a syrup, have been recommended in coughs and other disorders of the breast. Our pharmacopœias, nevertheless, have deservedly rejected this syrup, as common practice has almost done the balsams. Solutions of the hepar in water have been also recommended in herpetic and other cutaneous affections. Some physicians have even employed this solution, in a large quantity, as a bath for the cure of psora; and in cases of tinea capitis it has often been used by way of lotion.

The hepar, digested in rectified spirit of wine, imparts a rich gold colour, a warm, somewhat aromatic taste, and a peculiar, not ungrateful smell. A tincture of this kind is kept in the shops under the name of another mineral. The hepar sulphuris has been by some strongly recommended to prevent the effects of mineral poison.

Sulphurated oil and sulphurated petroleum. L.

Take of flowers of sulphur, four ounces; olive oil, sixteen ounces. Boil the flowers of brimstone with the oil, in a pot slightly covered, until they be united.

In the same manner is made *sulphurated petroleum*.

These articles are analogous to what had formerly a place in our pharmacopœias under the titles of *balsamum sulphuris simpl. s. crassum, et Barbadosense*. And besides these a place was also given to the *balsamum sulphuris unisatum, terclinclinatum, &c.* While these articles, however, are now banished from our pharmacopœias, even those retained are less in use than formerly.

These preparations are more conveniently and safely made in a tall glass body, with the mouth at least an inch in diameter, than in the circulatory or close vessels in which they have commonly been directed to be prepared: for when the sulphur and oil begin to act vehemently upon each other, they not only rarify into a large volume, but likewise throw out impetuously great quantities of an elastic vapour; which, if the vessels be closed, or the orifices not sufficient to allow it

Preparations and Compositions.

it a free exit, will infallibly burst them. Hoffman relates a very remarkable history of the effects of an accident of this kind. In the vessel above recommended the process may be completed, without danger, in four or five hours, by duly managing the fire, which should be very gentle for some time, and afterwards increased so as to make the oil just bubble or boil; in which state it should be kept till all the sulphur appears to be taken up.

Essential oils, employed as menstrua for sulphur, undergo a great alteration from the degree of heat necessary for enabling them to dissolve the sulphur; and hence the balsams have not near so much of their flavour as might be expected. It should therefore seem more eligible to add a proper quantity of the essential oils to the simple balsam: these readily incorporate by a gentle warmth, if the vessel be now and then shaken. We may thus compose a balsam more elegant than those made in the manner formerly recommended, and which retains so much of the flavour of the oil as is in some measure sufficient to cover the taste of the sulphur, and render it supportable.

The balsams of sulphur have been strongly recommended in coughs, consumptions, and other disorders of the breast and lungs; but the reputation which they have had in these cases does not appear to have been built on any fair trial or experience of their virtues. They are manifestly hot, acrimonious, and irritating; and therefore should be used with the utmost caution. They have frequently been found to injure the appetite, offend the stomach and viscera, parch the body, and occasion thirst and febrile heats. The dose of the simple balsam is from ten to forty drops: those with essential oils are not given in above half these quantities. Externally, they are employed for cleansing and healing foul running ulcers. Boerhaave conjectures that their use in these cases gave occasion to the virtues ascribed to them when taken internally.

Precipitated sulphur. I.

253 Take of sulphurated kali, six ounces; distilled water one pound and a half; vitriolic acid, diluted, as much as is sufficient. Boil the sulphurated kali in the distilled water until it be dissolved. Filter the liquor through paper, to which add the vitriolic acid. Wash the precipitated powder by often pouring on water till it becomes insipid.

This preparation is not so white as that of the last pharmacopœia, which was made with quicklime; and which in some pharmacopœias had the name of *milk of sulphur*.

Pure milk of sulphur is not different in quality from pure sulphur itself; to which it is preferred in unguents, &c. only on account of its colour. The whiteness does not proceed from the sulphur having lost any of its parts in the operation, or from any new matter superadded: for if common sulphur be ground with alkaline salts, and set to sublime, it rises of a white like colour, the whole quantity of the alkali remaining unchanged; and if the milk be melted with a gentle fire, it returns into yellow sulphur again.

It may be observed, that the name *lac sulphuris*, or *milk of sulphur*, applied among us to the precipitate, is by the French writers confined to the white liquor before the precipitate has fallen from it.

CHAP. X. Preparations of Antimony.

ANTIMONY is composed of a metal, united with sulphur or common brimstone.

If powdered antimony be exposed to a gentle fire, the sulphur exhales; the metallic part remaining in form of a white calx, reducible, by proper fluxes, into a whitish brittle metal, called *regulus*. This is readily distinguished from the other bodies of that class, by its not being soluble in aquafortis; its proper menstruum is aqua-regia.

If aqua-regia be poured on crude antimony, the metallic part will be dissolved; and the sulphur thrown out, partly to the sides of the vessel and partly to the surface of the liquor, in the form of a greyish yellow substance. This, separated and purified by sublimation, appears on all trials the same with pure common brimstone.

The metal freed from the sulphur naturally blended with it, and afterwards fused with common brimstone, resumes the appearance and qualities of crude antimony.

The antimonial metal is a medicine of the greatest power of any known substance; a quantity too minute to be sensible in the tenderest balance, is capable of producing violent effects, if taken dissolved or in a soluble state. If given in such a form as to be immediately miscible with the animal fluids, it proves violently emetic; if so managed as to be more slowly acted on, cathartic; and in either case, if the dose be extremely small, diaphoretic. Thus, though vegetable acids extract so little from this metal, that the remainder seems to have lost nothing of its weight, the tinctures prove in large doses strongly emetic, and in smaller ones powerfully diaphoretic. The *regulus* has been cast into the form of pills, which acted as violent cathartics, though without suffering any sensible diminution of weight in their passage through the body; and this repeatedly for a great number of times.

This metal, divested of the inflammable principle which it has in common with other metallic bodies that are reducible to a calx, becomes indissoluble and inactive. The calx nevertheless, urged with a strong fire, melts into a glass, which is as easy of solution, and as violent in operation, as the *regulus* itself: the glass, thoroughly mixed with such substances as prevent its solubility, as wax, resin, and the like, is again rendered mild.

VEGETABLE acids, as has already been observed, dissolve but an extremely minute portion of this metal: the solution nevertheless is powerfully emetic and cathartic. The nitrous and vitriolic acids only corrode it into a powder, to which they adhere so slightly as to be separable in a considerable degree by water, and totally by fire, leaving the *regulus* in form of a calx similar to that prepared by fire alone. The marine acid has a very different effect; this reduces the *regulus* into a violent corrosive; and though it difficultly unites, yet it adheres so very closely as not to be separable by any ablution, nor by fire, the *regulus* arising along with it. The nitrous or vitriolic acids expel the marine, and thus reduce the corrosive into a calx similar to the foregoing.

Sulphur remarkably abates the power of this metal: and hence crude antimony, in which the *regulus*

Preparations and Compositions

254

Prepara-
tions and
Composi-
tions.

It appears to be combined with sulphur, from one-fourth to one-half its weight, proves altogether mild.

If a part of the sulphur be taken away by such operations as do not destroy or calcine the metal, the remaining mass becomes proportionally more active.

The sulphur of antimony may be expelled by deflagration with nitre: the larger the quantity of nitre, to a certain point, the more of the sulphur will be dissipated, and the preparation will be the more active. If the quantity of nitre be more than sufficient to consume the sulphur, the rest of it, deflagrating with the inflammable principle of the regulus itself, renders it again mild.

The sulphur of antimony is likewise absorbed in fusion by certain metals and by alkaline salts. These last, when united with sulphur, prove a menstruum for all the metals (zinc excepted); and hence, if the fusion be long continued, the regulus is taken up, and rendered soluble in water.

From these particulars with respect to antimony, it may naturally be concluded, that it not only furnishes us with an useful and active medicine, but that it may also be exhibited for medical purposes under a great variety of different forms, and that the effects of these will be considerably diversified. And this has in reality been the case. For further information respecting antimony, and its uses in medicine, we refer our readers to the articles ANTIMONY; MATERIA MEDICA, p. 653, &c.; and CHEMISTRY-Index. But although there is perhaps no preparation there mentioned, which is not fitted to serve some useful purpose; yet the colleges both of London and Edinburgh have now restricted the number of preparations in their pharmacopœias to a few only. And it is highly probable, that from the proper employment of them, every useful purpose to be answered by antimony may be accomplished.

Calined antimony. L.

255 Take of antimony, powdered, eight ounces; nitre, powdered, two pounds. Mix them, and cast the mixture by degrees into a red hot crucible. Burn the white matter about half an hour; and, when cold, powder it; after which wash it with distilled water.

In the last edition of the London Pharmacopœia this preparation had the name of *calx of antimony*; and it may be considered as at least very nearly approaching to some other antimonials of the old pharmacopœias, particularly to the nitrated diaphoretic antimony, washed ditto, and sibiated nitre; none of which are now received as separate formulas of the Edinburgh pharmacopœia, and indeed even the calx of antimony itself, at least as thus prepared, has now no place in that pharmacopœia.

The calx of antimony, when freed by washing from the saline matter, is extremely mild, if not altogether inactive. Hoffman, Lemery, and others, assures us, that they have never experienced from it any such effects as its usual title imports: Boerhaave declares, that it is a mere metallic earth, entirely destitute of all medicinal virtue: and the committee of the London college admit that it has no sensible operation. The common dose is from five grains to a scruple, or half a dram; though Willson relates, that he has

known it given by half ounces, and repeated two or three times a day, for several days together.

Some report that this calx, by keeping for a length of time, contrasts an emetic quality: From whence it has been concluded, that the powers of the reguline part are not entirely destroyed; that the preparation has the virtues of other antimonials which are given as alteratives; that is, in such small doses as not to stimulate the prime viæ; and that therefore diaphoretic antimony, or calcined antimony, as it is now more properly styled, is certainly among the mildest preparations of that mineral, and may be used for children, and similar delicate constitutions where the stomach and intestines are easily affected. The observations, however, from which these conclusions are drawn, does not appear to be well founded: Ludovici relates, that after keeping the powder for four years, it proved as mild as at first: and the Strasburgh pharmacopœia, with good reason, suspects, that where the calx has proved emetic, it had either been given in such cases as would of themselves have been attended with this symptom (for the great alexipharmac virtues attributed to it have occasioned it to be exhibited even in the more dangerous malignant fevers, and other disorders which are frequently accompanied with vomiting); or that it had not been sufficiently calcined, or perfectly freed from such part of the regulus as might remain uncalcined. The uncalcined part being grosser than the true calx, the separation is effected by often washing with water, in the same manner as directed for separating earthy powders from their grosser parts.

It has been observed, that when diaphoretic antimony is prepared with nitre abounding with sea-salt, of which all the common nitre contains some portion, the medicine has proved violently emetic. This effect is not owing to any particular quality, of the sea-salt, but to its quantity, by which the proportion of the nitre to the antimony is rendered less.

The *nitrum sibiatum*, as it was called, produced by the deflagration of the sulphur of the antimony with the nitre in the same manner as the *sal polybrevis*, from which it differs no otherwise than in retaining some portion of the antimonial calx.

Notwithstanding the doubts entertained by some respecting the activity of the antimonium calcinatum, yet the London college have in our opinion done right in retaining it. For while it is on all hands allowed that it is the mildest of our antimonials, there are some accurate observers who consider it by no means inefficacious. Thus Dr Healde tells us, that he has been in the habit of employing it for upwards of 40 years, and is much deceived, if, when genuine, it be not productive of good effects.

Nitrated calx of antimony. E.

256 Take of antimony calcined for making the glass of antimony, and nitre, equal weights. Having mixed, and put them into a crucible, let them be heated, so that the matter shall be of a red colour for an hour: then let it be taken out of the crucible, and, after beating it, wash it repeatedly with warm water till it be insipid.

Although this preparation agrees nearly in name with

the

Prepara-
tions and
Composi-
tions.

the preceding, and has been considered as being nearly a complete calx of antimony, yet there can be no doubt that it is a medicine of a much more active nature than the former; and in place of being one of the milder of the antimonials, it often operates with great violence when given in doses of a few grains only.

But as the effects of every preparation of antimony, not already conjoined with an acid, must depend on the quantity and condition of the acid in the stomach, so the ablation of the base of the nitre in this process gives full power to the acid of the stomach to act as far as possible on the calx; whereas, when the unwashed calx is employed, a great quantity of the acid in the stomach is neutralized by the alkaline base of the nitre adhering to the calx. The nitrated calx of antimony is supposed to be nearly the same with the article which has been so much celebrated, and has had such an extensive sale under the title of *Dr James's fever-powder*. And it was as an article which might be employed in the place of James's powder, that the Edinburgh college introduced this into their pharmacopœia. There is, however, reason to believe, that the preparation of James's powder is somewhat different from that here directed; but their effects, as far as our observation goes, appear to be very nearly the same.

The nitrated calx of antimony has been thought by some preferable to emetic tartar, where the permanent effects of a long continued nausea are required, and where we wish our antimonials to pass the pylorus and produce purging. But, like every other preparation where the reguline part is only rendered active by the acid in the stomach, the nitrated calx of antimony is in all cases of uncertain operation: sometimes proving perfectly inert, and at other times very violent in its effects. The dose is generally 10 or 12 grains, and this is often given all at once; an inconvenience not attending the emetic tartar; the quantity and effects of which we can generally measure with surprising minuteness.

There is, however, reason to believe, that by means of James's powder, and the nitrated calx, an artificial termination of fever is sometimes accomplished, and that too more frequently than by emetic tartar. This perhaps may sometimes be the consequence of the violence with which they operate. At the same time it must be admitted, that even the most violent operation by no means ensures an immediate recovery, but that on the contrary it is sometimes manifestly attended with bad effects.

Crocus of antimony.

257 Take of antimony, powdered; nitre, powdered, of each one pound; sea-salt, one ounce. Mix, and put them by degrees into a red-hot crucible, and melt them with an augmented heat. Pour out the melted matter; and, when cold, separate it from the scoria. *L.*

Equal parts of antimony and nitre are to be injected by degrees into a red-hot crucible; when the detonation is over, separate the reddish metallic matter from the whitish crust; beat it into a powder, and edulcorate it by repeated washings with hot water, till the water comes off inspid. *L.*

Vol. XIV.

Here the antimonial sulphur is almost totally consumed, and the metallic part left divested of its corroctor. These preparations, given from two to six grains, generally act as violent emetics, greatly disordering the constitution. But the operation, like that of every preparation of antimony whose reguline part is not joined with an acid, must be liable to variations, according to the quantity and condition of the acid in the stomach. Their principal use is in unusual cases, as the basis of some other preparations; and among the farriers, who frequently give to horse an ounce or two a day, divided into different doses as an alternative: in these, and other quadruple, this medicine acts chiefly as a diaphoretic.

The chemists have been accustomed to make the crocus with a less proportion of nitre than what is directed above; and without any further melting than what ensues from the heat which the matter acquires by deflagration, which, when the quantity is large, is very considerable: a little common salt is added to promote the fusion. The mixture is put by degrees into an iron pot or mortar, somewhat heated, and placed under a chimney: when the first ladleful is in, a piece of lighted charcoal is thrown to it, which sets the matter on fire; the rest of the mixture is then added by little and little: the deflagration is soon over, and the whole appears in perfect fusion: when cold, a considerable quantity of scoriae is found on the surface; which scoriae are easily knocked off with a hammer. The crocus prepared after this manner is of a redder colour than that of the former editions of the London pharmacopœia. And indeed the method now directed by the London college may be considered as founded on this: It differs principally from that of the Edinburgh college in the employment of the sea salt, by which the process is much facilitated.

Muriated antimony. L.

Take of the crocus of antimony, powdered; vitriolic acid, each one pound; dry sea-salt, two pounds. 258
Pour the vitriolic acid into a retort, adding by degrees the sea-salt and crocus of antimony, previously mixed; then distil in a sand-bath. Let the distilled matter be exposed to the air several days, and then let the fluid part be poured off from the dregs.

Butter of antimony. E.

Take of crude antimony, one part; corrosive sublimate of mercury, two parts. Grind them first separately; then thoroughly mix them together, taking the utmost care to avoid the vapours. Put the mixture into a coated glass retort (having a short wide neck), so as to fill one half of it: the retort being placed in a sand-furnace, and receiver adapted to it, give first a gentle heat, that only a dewy vapour may arise: the fire being then increased, an oily liquor will ascend and congeal in the neck of the retort, appearing like ice, which is to be melted down by a live coal cautiously applied. This oily matter is to be rectified in a glass retort into a pellucid liquor. 259

The process here directed by the Edinburgh college, and which is nearly the same with what stood in

Y y the

the former edition of the London pharmacopœia, is extremely dangerous, inſomuch that even the life of the operator, though tolerably verſed in common pharmacy, may be much endangered for want of due care. Boerhaave relates, that one who from the title he gives him is not to be ſuppoſed inexpert in chemical operations, or unacquainted with the danger attending this, was ſuffocated for want of proper care to prevent the burſting of the retort. The fumes which ariſe, even upon mixing the antimony with the ſublimate, are highly noxious, and ſometimes iſſue ſo copiouſly and ſuddenly, as very difficultly to be avoided. The utmoſt circumſpection therefore is neceſſary.

The cautiſic, or butter as it is called, appears to be a ſolution of the metallic part of the antimony in the marine acid of the ſublimate: the ſulphur of the antimony and the mercury of the ſublimate, remain at the bottom of the retort united into an aſthiops. This ſolution does not ſucceed with ſpirit of ſalt in its liquid ſtate, and cannot be effected, unleſs (as in the caſe of making ſublimate) either the acid be highly concentrated, and both the ingredients ſtrongly heated; or when the antimony is expoſed to the vapours of the acid diſtilled from the black calx of manganese. By this laſt proceſs a perfect ſolution of the regulus of antimony in the muriatic acid is effected. Of this more ſimple, more ſafe, and leſs expenſive method of preparing muriated antimony, an account is given by Mr Ruffel in the Tranſactions of the Royal Society of Edinburgh.

If regulus of antimony were added in the diſtillation of ſpirit of ſea ſalt without water, a ſolution would alſo be made.

The method however, now directed by the London college, in which vitriolic acid and ſea ſalt are employed to give a double elective attraction, is perhaps to be conſidered as preferable to any of the others. In this they have followed very nearly the directions given in the pharmacopœia Suecica, which are taken from the proceſs of Mr Scheele.

When the congealed matter that ariſes into the neck of the retort is liquefied by the mixture of the air, it proves leſs corroſive than when melted down and rectified by heat; though it ſeems, in either caſe, to be ſufficiently ſtrong for the purpoſes of conſuming fungous fleſh and the callous lips of ulcers. It is remarkable, that though this ſaline concrete readily and almoſt entirely diſſolves by the humidity of the air, only a ſmall quantity of white powder ſeparating, it nevertheleſs will not diſſolve on putting water to it directly; even when previously liquefied by the air; the addition of water will precipitate the ſolution. And accordingly, by the addition of water is formed that one celebrated article known by the title of *mercurius vitæ*, or *Alyroth's powder*. This preparation, though never uſed by itſelf, is employed both by the Edinburgh and by ſome of the foreign colleges, in the formation of emetic tartar, the moſt uſeful of all the antimonials. And although chemiſts are not altogether agreed with regard to the beſt mode of making the tartarized antimony, yet we ſhall afterwards have occaſion to obſerve, when treating of that article, that the preparation of it from the muriated antimony, or rather from its precipitate (*Algeroth's powder*), is perhaps the beſt mode which has

yet been practiſed. And were it even with no other Preparation than this; a ſafe, eaſy, and cheap method of forming a muriated antimony, may be conſidered as an important improvement in our pharmacopœias. Prepara-
tions and
Composi-
tions.

Antimonial powder. L.

Take of antimony, coarſely powdered, hartſhorn ſhavings, each two pounds; mix, and put them into a wide red hot iron pot, ſtirring conſtantly till the maſs acquires a grey colour. Powder the matter when cold, and put it into a coated crucible. Lut: to it another crucible inverted, which has a ſmall hole in its bottom: augment the fire by degrees to a red heat, and keep it ſo for two hours. Laſtly, reduce the matter, when cold, to a very fine powder.

In this preparation the metallic part of the antimony in a ſtate of calx will be united with that part of the hartſhorn which is indeſtruſtible by the action of fire, viz. its abſorbent earth. If this powder be properly prepared, it is of a white colour. It is a mild antimonial preparation, and is given as an alterative from three to ſix grains for a doſe. In this quantity, however, it ſometimes creates nauſea, and even vomits. In larger doſes it proves emetic, and operates by ſtool.

Precipitated ſulphur of antimony. L.

Take of antimony, powdered, two pounds; water of pure kali, four pints; diſtilled water, three pints; Mix, and boil them with a ſlow fire for three hours, conſtantly ſtirring, and adding the diſtilled water as it ſhall be wanted: ſtrain the hot ley through a double linen cloth, and into the liquor, whiſt yet hot, drop by degrees as much diluted vitriolic acid as is ſufficient to precipitate the ſulphur. Waſh off, with warm water, the vitriolated kali.

Golden ſulphur of antimony. E.

Boil, in an iron pot, four pounds of cautiſic ley diluted with three pints of water, and throw in by degrees two pounds of powdered antimony; keeping them continually ſtirring with an iron ſpatula for three hours, over a gentle fire, and occaſionally ſupplying more water. The liquor loaded with the ſulphur of antimony being then ſtrained through a woollen cloth, drop into it gradually, while it continues hot, ſo much ſpirit of nitre, diluted with an equal quantity of water, as ſhall be ſufficient to precipitate the ſulphur which is afterwards to be carefully waſhed with hot water.

The foregoing preparations are not ſtrictly ſulphurs; they contain a conſiderable quantity of the metallic part of the antimony, which is reducible from them by proper fluxes. Theſe medicines muſt needs be liable to great variation in point of ſtrength; and in this reſpect they are, perhaps the moſt precarious, though ſome have affirmed that they are the moſt certain, of the antimonial medicines.

They prove emetic when taken on an empty ſtomach, in a doſe of four, five, or ſix grains; but at preſent they are ſcarcely preſcribed with this intention; being chiefly uſed as alterative deobſtruent, particularly in cutaneous diſorders. Their emetic quality is eaſily blunted, by making them up into pills with reſins

262

261

262

Prepara-
tions and
Composi-
tions.

skins or extracts, and giving them on a full stomach; with these cautions they have been taken in the quantity of 16 grains a-day, and continued for a considerable time, without occasioning any disturbance upwards or downwards. As their strength is precarious, they should be taken at first in very small doses, and increased by degrees according to their effect.

A composition of the golden sulphur, with sweet mercury, has been found a powerful, yet safe alterative, in cutaneous disorders; and has completed a cure after salivation had failed. In venereal cases, likewise, this medicine has produced excellent effects. A mixture of equal parts of the sulphur and calomel (well triturated together, and made into pills with extracts, &c.) may be taken from four to eight or ten grains, morning and night; the patient keeping moderately warm, and drinking after each dose a draught of a decoction of the woods, or other similar liquor. This medicine generally promotes perspiration, scarcely occasioning any tendency to vomit or purge, or affecting the mouth.

Tartarized antimony. L.

- 263 Take of crocus of antimony, powdered, one pound and an half; crystals of tartar, two pounds; distilled water two gallons: boil in a glass vessel about a quarter of an hour; filter through paper, and set aside the strained liquor to crystallize.

Emetic tartar. E.

- 264 Take of the butter of antimony what quantity you choose; pour it into warm water, in which so much of the purified vegetable fixed alkali has been previously dissolved, that the antimonial powder may be precipitated, which, after being well washed, is to be dried. Then to five pounds of water add of this powder nine drams, of crystals of tartar, beat into a very fine powder, two ounces and a half, boil for a little till the powders be dissolved. Let the strained solution be slowly evaporated in a glass vessel to a pellicle, so that crystals may be formed.

We have here two modes of making the most common, and perhaps we may add the most useful, of all the antimonial preparations, long known in the shops under the name of *emetic tartar*. These modes differ considerably from each other; but in both, the reguline part of the antimony is united with the acid of the tartar. It is perhaps difficult to say to which mode of preparation the preference is to be given: for on this subject the best chemists are still divided in their opinion. The mode directed by the London college is nearly the same with that in the former editions of their pharmacopœia, while that now adopted by the Edinburgh college in which they have nearly followed the Pharmacopœia Rossica, is of later date. That in both ways a good emetic tartar may be formed, is very certain: but in our opinion, when it is formed of the precipitate from the muriatic acid, or the *poudre d'Agrostis*, as it has been called, there is the least chance of its being uncertain in its operation: and this method comes recommended to us on the authority of Bergman, Scheele, and some other of the first names in chemistry. Bergman advises, that the calx be precipitated, by simple water, as being least liable to variation; and this is the direction followed in the Phar-

macopœia Rossica. But when the calx is precipitated by an alkaline ley, as is directed by the Edinburgh college, it is more certainly freed from the muriatic acid, and will of course be milder.

In the after part of the process, whether precipitate or crocus have been used, the quantity of the antimonial ought always to be some drams more than is absolutely necessary for saturating the acid of tartar, so that no crystals may shoot which are not impregnated with the active metallic part of the antimony. And in order to secure an uniform strength, some attention is necessary in collecting the crystals, as some may contain more metal than others. After they are all separated from the liquor, they ought to be beat together in a glass mortar into a fine powder, that the medicine may be of uniform strength.

Emetic tartar is, of all the preparations of antimony, the most certain in its operation.

It will be sufficient, in considering the medicinal effects of antimonials, that we should observe, once for all, that their emetic property depends on two different conditions of the reguline part: the first is where the reguline part is only active, by being rendered so from meeting with an acid in the stomach: the second is where the reguline part is already joined with an acid, rendering it active. It is obvious, that those preparations, reducible to the first head, must always be of uncertain operation. Such then is the equal uncertainty in the chemical condition and medicinal effects of the croci, the hepata, and the calces; all of which processes are different steps or degrees of freeing the reguline part from sulphur and phlogiston. It is equally plain, that the preparations coming under the second head must be always constant and certain in their operation. Such a one is emetic tartar, the dose and effects of which we can measure with great exactness.

The title of this medicine expresses its principal operation. It is one of the best of the antimonial emetics, acting more powerfully than the quantity of crocus contained in it would do by itself, though it does not so much ruffle the constitution. And indeed antimonials in general, when thus rendered soluble by vegetable acids, are more safe and certain in their effects than the violent preparations of that mineral exhibited by themselves; the former never varying in their action from a difference in the food taken during their use, or other similar circumstances; which occasioning more or less of the others to be dissolved, make them operate with different degrees of force. Thus, crude antimony, where acid to it has been liberally taken, has sometimes proved violently emetic; whilst in other had circumstances it has had no such effect.

The dose of emetic tartar, when designed to produce the full effect of an emetic, is from two to four grains. It may likewise be advantageously given in much smaller doses as a nauseating and sudorific medicine.

Vitriolized antimony. L.

- 265 Take of powdered antimony, four ounces. Caline in a broad earthen vessel, with a fire gradually raised, stirring with an iron rod till it no longer emits a sulphureous smoke. Put this powder into a crucible, to as to fill two thirds of it. A cover being fitted

Prepara-
tions and
Composi-
tions.

on, make a fire under it, at first moderate, afterwards stronger, until the matter be melted. Pour out the melted glass.

Glass of antimony. E.

266 Strew antimony, beat into a coarse powder like sand, upon a shallow unglazed earthen vessel, and apply a gentle heat underneath, that the antimony may be heated slowly; keeping it, at the same time continually stirring to prevent it from running into lumps. White vapours of a sulphurous smell will arise from it. If they cease to exhale with the degree of heat first applied, increase the fire a little, so that vapours may again arise: go on in this manner, till the powder, when brought to a red heat, exhales no more vapours. Melt the calx in a crucible with an intense heat, till it assumes the appearance of melted glass; then pour it out on a heated brass plate or dish.

The calcination of antimony, in order to procure transparent glass, succeeds very slowly, unless the operator be wary and circumspect in the management of it. The most convenient vessel is a broad shallow dish, or a smooth flat tile, placed under a chimney. The antimony should be the purer sort, such as is usually found at the apex of the cones; this, grossly powdered, is to be evenly spread over the bottom of the pan, so as not to lie above a quarter of an inch thick on any part. The fire should be at first no greater than is just sufficient to raise a fume from the antimony, which is to be now and then stirred: when the fumes begin to decay, increase the heat, taking care not to raise it so high as to melt the antimony, or run the powder into lumps; after some time the vessel may be made red-hot, and kept in this state until the matter will not, upon being stirred, any longer fume. If this part of the process be duly conducted, the antimony will appear in an uniform powder, without any lumps, and of a grey colour.

With this powder fill two-thirds of a crucible, which is to be covered with a tile, and placed in a wind-furnace. Gradually increase the fire till the calx be in perfect fusion, when it is to be now and then examined by dipping a clean iron wire into it. If the matter which adheres to the end of the wire appears smooth and equally transparent, the vitrification is completed, and the glass may be poured out upon a hot smooth stone or copperplate, and suffered to cool slowly to prevent its cracking and flying in pieces. It is of a transparent yellowish red colour.

The glass of antimony usually met with in the shops, is said to be prepared with certain additions; which may, perhaps, render it not so fit for the purpose here designed. By the method above directed, it may be easily made of the requisite perfection without any addition.

As antimony may be rendered nearly or altogether inactive by calcination, it might be expected that the calx and glass of the present process would be likewise inert. But here the calcination is far less perfect than in the other case, where the inflammable principle of the regulus is totally burnt out by desiccation with nitre; there the calx is of perfect whiteness, and a glass made from that calx (with the addition of any saline flux, for of itself it will not vitrify) has little colour:

but here so much of the inflammable principle is left, Preparations and Compositions. that the calx is grey, and the glass of a high colour. The calcined antimony is said by Boerhaave to be violently emetic. Experience has shown that the glass is so, inasmuch as to be unsafe for internal use. At present it is chiefly employed in forming some other antimonial preparations, particularly the cerated glass of antimony, the next article to be mentioned; and the wine of antimony, afterwards to be treated of under the head of wines. It is also not unfrequently employed in the formation of emetic tartar; and it was directed for that purpose in the last edition of the Edinburgh pharmacopœia, being perhaps even superior to the crocus of antimony.

Cerated glass of antimony. E.

267 Take of yellow wax, a dram; glass of antimony, reduced into powder, an ounce. Melt the wax in an iron vessel, and throw into it the powdered glass: keep the mixture over a gentle fire for half an hour, continually stirring it: then pour it out on paper, and when cold grind it into powder.

The glass melts in the wax with a very gentle heat: after it has been about twenty minutes on the fire, it begins to change its colour, and in ten more comes near to that of Scotch snuff; which is a mark of its being sufficiently prepared; the quantity set down above loses about one dram of its weight in the process.

This medicine was for some time much esteemed in dysenteries: several instances of its good effects in those cases may be seen in the fifth volume of the Edinburgh Essays, from which the above remarks on the preparations are taken. The dose is from two or three grains to twenty, according to the age and strength of the patient. In its operation, it makes some persons sick and vomit; it purges almost every one: though it has sometimes effected a cure without occasioning any evacuation or sickness. It is now, however, much less used than formerly.

Mr Geoffroy gives two pretty singular preparations of glass of antimony, which seem to have some affinity with this. One is made by digesting the glass, very finely levigated, with a solution of mastich made in spirit of wine, for three or four days, now and then shaking the mixture; and at last evaporating the spirit so as to leave the mastich and glass perfectly mixed. Glass of antimony thus prepared, is said not to prove emetic, but to act merely as a cathartic, and that not of the violent kind. A preparation like this was first published by Hartman, under the name of *Clyster*.

The other preparation is made by burning spirit of wine on the glass three or four times, the powder being every time exquisitely rubbed upon a marble. The dose of this medicine is from ten grains to 20 or 30: it is said to operate mildly both upwards and downwards and sometimes to prove sudorific.

Cerise of antimony. Drum.

268 Take of regulus of antimony, one part; nitre, three parts. Desagrate them together in the manner directed for the calcined antimony.

The result of this process and that formerly directed for the calcined antimony are nearly the same.

It is not necessary to use so much nitre here as when antimony

Preparations and Compositions.

antimony itself is employed: for the sulphur which the crude mineral contains, and which requires for its dissipation nearly an equal weight of nitre to the antimony, is here already separated. Two parts of nitre to one of the regulus are sufficient. It is better, however, to have an over, than an under, proportion of nitre, lest some parts of the regulus should escape being sufficiently calcined.

It may be proper to observe, that though crude antimony and the regulus yield the same calces, yet the salts separated in washing the calces are very different. As crude antimony contains common sulphur, the acid of the sulphur unites with the alkaline basis of the nitre, and the result is a neutral salt. As the regulus contains the phlogistic, or inflammable principle, but no sulphur, the nitre is alkalinised, as it would be by charcoal or such like inflammable bodies, and is at the same time rendered more acrimonious than the common alkaline salts; probably owing to the calx absorbing the air of the alkali. If only equal parts of the regulus and nitre be employed, and the fire kept up strong for an hour or more, the salt will prove more caustic than even the potential caustic of the shops. But the causticity of the salt will still be far greater, if, instead of the simple regulus of antimony, the martial regulus be used.

Kermes mineral. Syec.

269 Take of crude antimony, powdered, half a pound; fixed vegetable alkali, two pounds; boiling water, eight pounds. Boil them together in an iron pot for a quarter of an hour, continually stirring the mixture with an iron spatula, and filter as speedily as possible while it is hot. The filtered liquor, set in cool places, will soon deposit a powder, which must be repeatedly washed, first with cold and afterwards with warm water, until it be perfectly insipid.

This medicine has of late been greatly esteemed in France, especially under the names of *Kermes mineral*, *pulvis Caribæianus*, *poudre des Chartroux*, &c. It was originally a preparation of Glauber, and for some time kept a great secret, till at length the French king purchased the preparation from M. de la Ligerie, for a considerable sum, and communicated it to the public in the year 1720. In virtue, it is not different from the sulphurs above-mentioned; all of them owe their efficacy to a part of the regulus of the antimony, which the alkaline salt, by the mediation of the sulphur, renders soluble in water.

Chemists are, however, divided in their opinions, with respect to the precise chemical condition of the reguline part in the preparations called *Spata of antimony*. Some have alleged that they contain not a particle of alkaline salt: it is at any rate certain, that the quantity and condition of the reguline part must vary according to the different proportions of the ingredients, the time of the precipitation, the greater or less degree of causticity of the alkali employed, and several other circumstances. At best the whole of them are liable to the same uncertainty in their operation as the calces of antimony.

Panacea of antimony.

270 Take of antimony, six ounces; nitre, two ounces;

common salt, an ounce and a half; charcoal, an ounce. Reduce them into a fine powder, and put the mixture into a red-hot crucible, by half a pound at a time, continuing the fire a quarter of an hour after the last injection: then either pour the matter into a cone, or let it cool in the crucible; which when cold must be broken to get it out. In the bottom will be found a quantity of regulus; above this a compact liver-coloured substance; and on the top a more spongy mass: this last is to be reduced into powder, edulcorated with water, and dried, when it appears of a fine golden colour.

This preparation is supposed to have been the basis of Lockyer's pills, which were formerly a celebrated purge. Ten grains of the powder, mixed with an ounce of white sugar candy, and made up into a mass with macilage of gum tragacanth, may be divided into an hundred small pills; of which one, two or three, taken at a time, are said to work gently by stool and vomit. The compact liver-coloured substance, which lies immediately above the regulus, operates more feverely. This last appears to be nearly of the same nature with the crocus of antimony, and the former with the golden sulphur.

CHAP. XI. *Preparations of silver.*

Nitrat. silver. L.

271 Take of silver, one ounce; diluted nitrous acid, six ounces. Dissolve the silver in the nitrous acid, in a glass vessel, over a sand-heat; then evaporate with an heat gently raised: afterwards melt the residuum in a crucible, that it may be poured into proper forms, carefully avoiding too great a heat.

Salt of silver, commonly called *lunar caustic. E.*

272 Take of purest silver, beat into plates, and cut in pieces, four ounces; weak nitrous acid, eight ounces; purest water, four ounces. Dissolve the silver in a phial with a gentle heat, and evaporate the solution to dryness. Then put the mass into a large crucible, and apply the heat, at first gently, but augment it by degrees till the mass flows like oil; then pour it into iron moulds, previously heated, and greased with tallow.

These processes do not differ in any material particular. But the name of *nitrat. silver* is preferable to the more indefinite one of *Salt of silver*.

Strong spirit of nitre will dissolve somewhat more than half its weight of pure silver; and the weaker of the aquafortes formerly described, proportionally less, according to their quantity of pure nitrous acid. Sometimes this spirit contains a portion of the viscid or marine acids; which, however minute, renders it unfit for dissolving this metal, and should therefore be carefully separated before the solution be attempted. The method which the refiners employ for examining the purity of their aquafortis, and purifying it if necessary, is to let fall into it a few drops of a perfect solution of silver already made: if the liquor remains clear, and grow not in the least turbid or cloudy, it is fit for use; otherwise they add a small quantity more of the solution, which immediately causes the whole of a milky white colour; the mixture being then suffered to rest for some time, deposits a white sediment; from which it is carefully decanted, examined anew, and

Pr j r -
tons and
Compositions.

if need be, farther purified by a fresh addition of the solution.

The silver beat into thin plates, as directed in the second of the above processes, needs not be cut in pieces: the solution will go on the more speedily if they are only turned round into spiral circumvolutions, so as to be conveniently got into the glass, with care that the several surfaces do not touch each other. By this management, a greater extent of the surface is exposed to the action of the menstruum, than when the plates are cut in pieces and laid above each other. Good aquafortis will dissolve about half its weight of silver; and it is not advisable to use a greater quantity of the menstruum than is sufficient for effecting the solution, for all the surplus must be evaporated in the subsequent fusion.

It is necessary to employ very pure water: for if hard water were used in this process, the nitrous acid would forsake a part of the silver to join with the calcareous earth of the imperfect nitrous selenite; but a part of the silver would be precipitated.

The crucible ought to be large enough to hold five or six times the quantity of the dry matter; for it bubbles and swells up greatly, and is consequently apt to run over. During this time, also, little drops are now and then spouted up, whose causticity is increased by their heat, against which the operator ought therefore to be on his guard. The fire must be kept moderate till this ebullition ceases, and till the matter becomes consistent in the heat that made it boil before; then quickly increase the fire till the matter flows thin at the bottom like oil, when it is to be immediately poured into the mould, without waiting till the fumes cease to appear; for when this happens, the preparation proves not only too thick to run freely into the mould, but likewise less corrosive than it is expected to be.

For want of a proper iron mould, one may be formed of tempered tobacco-pipe clay, not too moist, by making in a lump of it, with a smooth stick first greased, as many holes as there is occasion for: pour the liquid matter into these cavities, and when congealed, take it out by breaking the mould. Each piece is to be wiped clean from the grease, and wrapt up in soft dry paper, not only to keep the air from acting on them, but likewise to prevent their corroding or discolouring the fingers in handling.

This preparation is a strong caustic; and is frequently employed as such for consuming warts and other fleshy excrescences, keeping down fungous flesh in wounds or ulcers, and other similar uses. It is rarely applied where a deep eschar is required, as in the laying open of imposthumations and tumours; for the quantity necessary for these purposes, liquefying by the moisture of the skin, spreads beyond the limits, within which it is intended to operate.

The lunar pills.

273

Dissolve pure silver in aquafortis, as in the foregoing process; and after due evaporation, let the liquor aside to crystallize. Let the crystals be again dissolved in common water, and mixed with a solution of equal their weight of nitre. Evaporate this mixture to dryness, and continue the exsiccation with a

gentle heat, keeping the matter constantly stirring till no more fumes arise.

Here it is necessary to continue the fire till the fumes entirely cease, as more of the acid is required to be dissipated than in the preceding process. The preparation is, nevertheless, in taste very sharp, intensely bitter and nauseous: applied to ulcers, it acts as a caustic, but it is much milder than the foregoing. Boerhaave, Boyle, and others, commend it highly in hydropic cases. The former assures us, that two grains of it made into a pill with crumb of bread and a little sugar, and taken on an empty stomach (some warm water, sweetened with honey, being drunk immediately after), purge gently without griping, and bring away a large quantity of water, almost without the patient's perceiving it: that it kills worms, and cures many inveterate ulcerous disorders. It is nevertheless cautions against using it too freely, or in too large a dose; and observes, that it always proves corrosive and weakening, especially to the stomach.

CHAP. XII. Preparations of iron.

Ammoniacal iron. L.

Take of iron filings, one pound; sal ammoniac, two pounds. Mix, and sublime. What remains at the bottom of the vessel mix by rubbing together with the sublimed matter, and again sublime. 274

Martial flowers, commonly called *Ens Veneris*. E.

Take of colcothar of martial vitriol, washed and well dried; sal ammoniac, equal weights. Having mixed them well, sublime. 275

Though the mode of preparation directed by the two colleges is here different, yet the preparation is fundamentally the same; and it is perhaps difficult to say which mode of preparation is to be preferred as the easiest and best.

The name of *ens veneris* has by some been very improperly applied to this preparation, as it contains not a particle of copper. The proper *ens veneris* is prepared from the blue vitriol; but, as we shall soon see, is often not materially different from the *martial flowers*.

The success of this process depends principally on the fire being hastily raised, that the sal ammoniac may not sublime before the heat be sufficient to enable it to carry up a sufficient quantity of the iron. Hence glass vessels are not so proper as earthen or iron ones: for when the former are used, the fire cannot be raised quickly enough, without endangering the breaking of them. The most convenient vessel is an iron pot: to which may be luted an inverted earthen jar, having a small hole in its bottom to suffer the elastic vapours, which arise during the operation, to escape. It is of advantage to thoroughly mix the ingredients together, moisten them with a little water, and then gently dry them; and to repeat the pulverization, humectation, and exsiccation, two or three times, or oftener. If this method be followed, the sal ammoniac may be increased to two or three times the quantity of the iron, or farther; and a single sublimation will often be sufficient to raise flower of a very deep orange colour.

This preparation is supposed to be highly aperient and

Preparations and Compositions.

and attenuating; though no otherwise so than the rest of the chalybeates, or at most only by virtue of the saline matter joined to the iron. It has been found of service in hysterical and hypochondriacal cases, and in distempers proceeding from a laxity and weakness of the solids, as the rickets. It may be conveniently taken in the form of a bolus, from two or three grains to ten; it is nauseous in a liquid form (unless in spirituous tincture); and occasions pills to swell and crumble, except such as are made of the gums.

Rust of iron L.

- 276 Take of iron-filings, one pound; expose them to the air, often moistening them with water, until they be corroded into rust; then powder them in an iron mortar, and wash off with distilled water the very fine powder. But the remainder, which cannot by moderate rubbing be reduced into a powder capable of being easily washed off, must be moistened, exposed to the air for a longer time, and again powdered and washed as before. Let the washed powder be dried.

Rust of iron, commonly called *prepared iron filings*. E.

Set purified filings of iron in a moist place, that they may turn to rust, which is to be ground into an impalpable powder.

The cleansing of iron filings by means of a magnet is very tedious, and does not answer so well as might be expected: for if they be rusty, they will not be attracted by it, or not sufficiently; nor will they by this means be entirely freed from brass, copper, or other metallic substances which may adhere to them. It appears from the experiments of Henckel, that of iron be mixed by fusion with even its own weight if any of the other metals, regulus of antimony alone excepted, the compound will be vigorously attracted by the loadstone. The rust of iron is to be procured at a moderate rate from the dealers in iron, free from any impurities, except such as may be washed off by water.

The rust of iron is preferable as a medicine to the calces or croci, made by a strong fire. Hoffman relates that he has frequently given it with remarkable success in obstinate chlorotic cases accompanied with excessive headachs and other violent symptoms; and that he usually joined with it pimpinella, arum root, and salt of tartar, with a little cinnamon and sugar. The dose is from four or five grains to twenty or thirty. Some have gone as far as a dram: but all the preparations of this metal answer best in small doses, which should rather be often repeated than enlarged.

Tartarized iron. L.

- 277 Take of filings of iron, one pound, powdered crystals of tartar, two pounds. Mix them with distilled water into a thick paste. Expose it to the air in an open earthen vessel for eight days; then grind the matter, dried in a bath of sand, to a very fine powder.

This is an useful preparation of iron in which that metal is chiefly brought to a saline state by means of the cream of tartar. It has now for the first time a place in the London pharmacopœia; but it had before

been introduced into some of the foreign ones, particularly the pharmacopœia Genevensis under the title of *mars tartarizatus*; and indeed it is almost precisely the same with the *mars solubilis* of the old editions of the Edinburgh pharmacopœia.

Vitriolated iron. L.

Take of filings of iron, vitriolic acid, each eight ounces; distilled water, three pints. Mix them in a glass vessel, and when the effervescence has ceased, place the mixture for some time upon hot sand; then pour off the liquor, straining it through paper: and after due exhalation set it aside to crystallize.

Vitriol of iron, or *salt of steel*. E.

Take of purified filings of iron, six ounces; vitriolic acid, eight ounces; water, two pounds and a half. Mix them; and when the effervescence ceases, let the mixture stand for some time upon warm sand; then strain the liquor through paper, and after due evaporation set it aside to crystallize.

During the dissolution of the iron an elastic vapour rises, which on the approach of flame catches fire and explodes, so as sometimes to burst the vessel. To this particular therefore the operator ought to have due regard.

This vapour is also noxious to animal life. It is the inflammable air of Dr Priestley.

The chemists are seldom at the trouble of preparing this salt according to the directions above given; but in its stead substitute common green vitriol, purified by solution in water, filtration, and crystallization. The only difference between the two is, that the common vitriol contains somewhat more metal in proportion to the acid; and hence in keeping, its green colour is much sooner debased by a rusty brownish cast. The superfluous quantity of metal may be easily separated by suffering the solution of the vitriol to stand for some time in a cold place, when a brownish yellow ochery sediment will fall to the bottom; or it may be perfectly dissolved, and kept suspended by a suitable addition of oil of vitriol. If the vitriol be suspected to contain any cupreous matter, which the common English vitriol seldom does, though almost all the foreign vitriols do, the addition of some bright iron wire to the solution will both discover, and effectually separate, that metal: for the acid quits the copper to dissolve a proportionable quantity of the iron; and the copper, in its separation from the acid, adheres to the undissolved iron, and forms a skin of a true copper colour on its surface. Even a vitriol of pure copper may on this principle, be converted into a small vitriol of iron.

But though the vitriolic acid appears in this operation to have so much stronger a disposition to unite with iron than with copper, that it totally rejects the latter when the former is presented to it; the operator may nevertheless give a dangerous impregnation of copper to the purest and most saturated solution of iron in the vitriolic acid, by the use of copper vessels. If the martial solution be boiled in a copper vessel, it never fails to dissolve a part of the copper, distinguishable by its giving a cupreous tincture to a piece of bright iron immersed in it. By the addition of the iron, the

copper

Preparations and Compositions.

Preparations and Compositions.

copper is separated: by boiling it again without iron, more of the copper is dissolved; and this may in like manner be separated by adding more iron.

The salt of steel is one of the most efficacious preparations of this metal; and not unrequently made use of in cachectic and chlorotic cases for exciting the uterine purgation, strengthening the tone of the viscera, and destroying worms. It may be conveniently taken in a liquid form, largely diluted with water: Boerhaave directs it to be dissolved in an hundred times its weight of water, and the solution to be taken in the dose of twelve ounces on an empty stomach, walking gently after it. Thus managed, he says, it opens the body, proves diuretic, kills and expels worms, tinges the excrements black, or forms them into a matter like clay, strengthens the fibres, and thus cures many different distempers. The quantity of vitriol in the above dose of the solution is fifty-seven grains and a half; but in common practice, such large doses of this strong chalybeate are never ventured on. Four or five grains, and in many cases half a grain, are sufficient for the intention in which chalybeate medicines are given. Very dilute solutions, as that of a grain of the salt in a pint of water, may be used as succedanea to the natural chalybeate waters, and will in many cases produce similar effects.

Colcothar of vitriol. E.

280 Let calcined vitriol be urged with a violent fire till it becomes of a very red colour.

In this preparation, the iron which had been brought to a saline state by means of the acid of vitriol, is again deprived of that acid by the action of fire. It may be considered therefore as differing in nothing from the residuum which remains in the retort, when vitriolic acid is distilled from martial vitriol. The colcothar is very early employed by itself for medical purposes; but it is used in the preparation of some other chalybeates, particularly the martial flowers, when prepared according to the method directed by the Edinburgh college.

Martial ethiops. Gen.

281 Take of the rust of iron, as much as you please: olive oil, a sufficient quantity to make it into a paste. Let this be distilled in a retort by a strong fire to dryness. Keep the residuum reduced to a fine powder in a close vessel.

An article under this name had formerly a place in some of the old pharmacopœias, and is described by Lemery in the Memoirs of the French Academy; but it was formed by a tedious process, continued for several months by the aid of water. Here the process is much shorter, and is supposed to give nearly the same product. Some have recommended it, on the supposition that the iron has here obtained in a very subtil state; but it is not in general supposed to have any advantage over the other more common chalybeates.

Open and astringent crecus of iron.

282 These are prepared by mixing iron filings with twice their weight of powdered sulphur, desigrating in a red-hot crucible; and in the one case keeping the preparation over the fire till it assumes a red colour:

in the other, by reverberating it for a long time in the most extreme degree of heat.

Preparations under these names still retain a place in some of the foreign pharmacopœias, but they are variously prepared. They may, however, be considered as possessing the same medical powers; and although the preparations mentioned above probably differ from each other in their virtues, yet that difference is not of such a nature as is imported by the titles by which they are usually distinguished. For all the preparations of iron probably act by an astringent quality; and that which is above denominated the *astringent crecus* has probably least effect in that way. At one period, these preparations were not unrequently in use; and they were given in the form of bolus, electuary, or pill, from a few grains to a scruple; but among us they are at present so little in use as to have no place in our pharmacopœias.

CHAP. XIII. Preparations of Mercury.

283 We have already treated of mercury in various parts of our work as we found occasion, and what we have already discussed it is unnecessary to repeat. See MERCURY, CHEMISTRY-Index, MATERIA MEDICA, p. 653. METALLURGY, and QUICKSILVER. On the whole, it appears evident that there is no article which has been employed for medical purposes in a greater variety of forms. The colleges of London and Edinburgh have admitted into their pharmacopœias only a few of these; but from the selection they have made, there is reason to believe that every useful purpose for which mercury has been employed may be answered; and these purposes are both numerous and considerable. For it is at least very generally allowed among intelligent practitioners, that there are few articles kept in the shops of our apothecaries which can be considered as so extensively useful.

Mercury or quicksilver, in its crude state, is a ponderous metallic fluid, totally volatile in a strong fire, and calcinable by a weaker one (though very difficultly) into a red powdery substance. It dissolves in the nitrous acid, is corroded by the vitriolic, but not acted on by the marine in its liquid state: it nevertheless may be combined with this last skillfully applied in the form of fume. Quicksilver unites by trituration with earthy, unctuous, resinous, and other similar substances, so as to lose its fluidity: triturated with sulphur, it forms a black mass, which by sublimation changes into a beautiful red one.

For the general virtues of the mercurial preparations, see some of the articles above referred to, and MEDICINE. Here we shall only observe, that while in certain circumstances they act as stimulants, and even as corrosives, to the parts to which they are applied; under a different management, when introduced into the habit, they seem to forward circulation through even the smallest and most remote vessels of the body; and may be so managed as to promote all the exertions. But while they thus operate as a powerful stimulus to the sanguiferous, and probably also to the lymphatic system, they seem to exert but little influence on the nervous system. By this means they prove eminently serviceable in some inveterate chronic disorders, proceeding from obstinate obstructions of the glands. Crude mercury has

Preparations and Compositions.

has no effect this way. Resolved into fume, or divided into minute particles, and prevented from reuniting by the interposition of other substances, it operates very powerfully, unless the dividing body be sulphur, which retrains its action. Combined with a small quantity of the mineral acids, it acts effectually, though in general mildly; with a larger it proves violently corrosive.

Purified quicksilver. L.

284 Take of quicksilver, tings of iron, each four pounds. Rub them together, and distil from an iron vessel.

As in the distillation of quicksilver glass retorts are very liable to be broken, an iron one is here with propriety directed: and by the addition of the filings of iron, matters which might otherwise arise with the quicksilver will be more apt to be detained in the retort. But still this happens so readily, even merely with that degree of heat which is necessary to elevate the mercury, that it is very doubtful whether much advantage be obtained from this process; and accordingly it has now no place in the pharmacopœia of the Edinburgh college.

Acetated quicksilver. L.

285 Take of purified quicksilver, one pound; diluted nitrous acid, two pounds; water of kali, as much as is sufficient. Mix the quicksilver with the acid in a glass vessel, and dissolve it in a sand-bath; then drop in by degrees the water of kali, that the calx of quicksilver may be precipitated; wash this calx with plenty of distilled water, and dry it with a gentle heat. These things being done, take of the calx of quicksilver, above described, one pound; acetic acid, as much as is necessary to dissolve the calx. Mix them in a glass vessel; and the solution being completed, strain it through paper; then evaporate it till a pellicle appears; and set it aside to crystallize. Keep these crystals in a vessel close stopped.

Of all the saline preparations of mercury, it has long been the opinion of the best chemists, that those in which it was brought to a saline form, by means of acetic acid, would be the mildest; and such a preparation was conjectured to be the basis of a celebrated pill, prepared and sold by Mr Keyser. It was, however, found to be a very difficult matter to imitate his pill, or to obtain a combination of mercury with the acetic acid: but not long since, the process for preparing these pills was published by authority at Paris after being purchased by the French king. The process here described though in some particulars much less operose than that of Mr Keyser, yet nearly approaches to it, and furnishes us with the mildest of the saline mercurials.

Calined quicksilver. L.

286 Take of purified quicksilver, one pound; expose the quicksilver in a flat bottomed glass cucurbit, to an heat of about 600 degrees in a sand-bath, till it becomes a red powder.

This preparation may now be made in a shorter time than by the process formerly directed in the London pharmacopœia which in general required several months; for the access of air, without which calcina-

tion cannot be performed, was then very much excluded. Still, however, the process is a tedious one, and might perhaps be improved. A vessel might be so contrived, as to occasion a continual flux of air over the surface of the mercury.

This preparation is highly esteemed in venereal cases, and supposed to be the most efficacious and certain of all the mercurials. It may be advantageously given in conjunction with opiates: a bolus or pill, containing from half a grain to two grains of this calx, and a quarter or half a gram or more of opium, with the addition of some warm aromatic ingredient, may be taken every night. Thus managed it acts mildly, though powerfully, as an alterative and diaphoretic: given by itself in larger doses, as four or five grains, it proves a rough emetic and cathartic.

Ash-coloured powder of mercury. E.

287 Take of quicksilver, weak nitrous acid, equal weights. Mix them so as to dissolve the quicksilver; dilute the solution with pure water, and add spirit of sal ammoniac as much as is sufficient to separate the mercury perfectly from the acid; then wash the powder in pure water, and dry it.

In this process the mercurial nitre is decomposed; the precipitate, therefore, is a calx of mercury, and the clear liquor a solution of nitrous ammoniac. From the great attraction which the nitrous acid has for phlogiston, or from its ready disposition to part with pure air, the precipitates of mercury from its solution in this acid are more completely in the state of a calx than those from any other menstruum. There are, however, several niceties to be observed in conducting this process. If we employ too small a proportion of acid, and assist the solution by heat, the solution will contain an excess of calx capable of being separated by the water; and the whole precipitate from such a solution would be of a white colour. If, on the other hand, we employ too large a proportion of acid, the mercury is then so far calcined as to be capable of being dissolved by the volatile alkali; and this might happen in proportion as the quantity should be superabundant to the neutralization of the acid. The use of the water is to dissolve the nitrous ammoniac as fast as it is formed, and thereby prevent it from falling down and mixing with the precipitate. It is necessary to employ the purest water. If such be used as contains a nitrous selenite, not only a part of the mercury may be precipitated by the base of the selenite, but this last might also be deposited by the succeeding addition of the alkali.

The ash-coloured powder of mercury has of late years been much celebrated for the cure of venereal affections. It was first proposed by Dr Saunders to be made by precipitating the mercury from calomel, as the best substitute for the tedious and expensive process of the precipitate *per se*, and of the grey powder produced by triture with gum arabic. From the testimony of Dr Home, and several other practitioners, we have no doubt of its being a very valuable preparation of mercury. It may be given in a bolus or wafer, in the quantity of from one six or seven grains: the dose being gradually increased according to its effects upon the person.

Preparations and Compositions.

Quicksilver with chalk. L.

Take of purified quicksilver, three ounces; powdered chalk, five ounces. Rub them together until the globules disappear.

In this preparation, as well as the two former, we have also the mercury in a state of calx; but in place of being brought to that state by the aid of fire or of acids, what may here be considered as calcination is effected by triture.

This preparation, had no place in the former editions of the London pharmacopœia. A preparation nearly similar indeed, under the title of *mercurius alkalisatus*, in which erabs eyes were employed instead of chalk, had a place in the old editions of the Edinburgh pharmacopœia, but was rejected from the edition of 1744, and has never again been restored. One reason for rejecting it was its being liable to gross abuse in the preparation, by the addition of some intermedium, facilitating the union of mercury with the absorbent earth, but diminishing or altering its power. The present preparation is liable to the same objection. Some, however, are of opinion, that when duly prepared, it is an useful alterative. But there can be little doubt, that the absorbent earth, by destroying acid in the alimentary canal, will diminish the activity of the mercurial calx.

Muriated quicksilver. L.

289 Take of purified quicksilver, vitriolic acid, each two pounds; dried sea-salt, three pounds and an half. Mix the quicksilver with the acid in a glass vessel, and boil in a sand heat until the matter be dried. Mix it, when cold, with the sea-salt, in a glass vessel; then sublime in a glass cucurbit, with a heat gradually raised. Lastly, let the sublimed matter be separated from the scoria.

Sublimate corrosive mercury. E.

290 Take of quicksilver, weak nitrous acid, each four ounces; calcined sea-salt, calcined vitriol, of each five ounces. Dissolve the quicksilver in the nitrous acid, and evaporate the solution to a white and thoroughly dry mass; then add the sea salt and vitriol. Having ground and mixed them well together, put the whole into a phial, one half of which they ought to fill; then sublime in sand, first with a gentle, but afterwards with an increased heat.

The sublimate prepared by either of these methods is the same, they both consist only of mercury and the acid of the sea-salt united together. In the process directed by the Edinburgh college, the materials being mixed and exposed to the fire, first the vitriol parts with its acid, which, dislodging those of the nitre and marine salt, takes their place. The marine acid, resolved into fume and assisted by the nitrous, dissolves the mercury, now also strongly heated. This acid, though it very difficultly acts on mercury, yet when thus once mixed with it, is more strongly retained thereby than any other acid. The nitrous spirit therefore, having nothing to retain it (for its own basis, and that of the sea salt are both occupied by the vitriolic, and that which the vitriolic forsook to unite with these, is now scarcely combinable with it), arises; leaving the mercury and marine acid to sublime together

when the heat shall be strong enough to elevate them. Some small portion of the marine spirit arises along with the nitrous; and hence this compound acid has been usually employed instead of the *compound aquafortis*, to which it is similar, for making the red corrosive.

It appears therefore that the vitriol, and the bases of the nitre and sea-salt, are of no farther use in this process, than as convenient intermediums for facilitating the union of the mercury with the marine acids. They likewise serve to afford a support for the sublimate to rest upon, which thus assumes the form of a placenta or cake.

This process, however, now adopted by the London college, is a better and more simple one. There the mercury corroded by the vitriolic acid into a white mass, is mixed with about an equal quantity of sea-salt, and set to sublime; the vitriolic acid quits the mercury to unite with the basis of the sea salt; and the acid of the sea-salt, now set at liberty, unites with the mercury, and sublimes with it into the compound required. The discovery of this method is generally attributed to Boulduc; though it is found also in Kunckel's *La oratorium Chymicum*. When the process is conducted in this way, the residuous matter is a pure Glauber's salt, and the sublimate is also free of ferruginous matter; a greater or less quantity of which is very generally carried up along with the mercury when vitriol of iron is employed. Boulduc's method has therefore the advantage in this, that the proportion of mercury in a given quantity of sublimate must be less liable to variation.

If the mercury be corroded by the nitrous acid instead of the vitriolic, the event will be the same; that acid equally quitting the mercury, and setting loose the marine; and the sublimate made by this method is the same with the foregoing; but as the quantity of fixed matter is smaller, it more difficultly assumes the form of a cake. It requires indeed some skill in the operator to give it this appearance when either process is followed. When large quantities are made, this form may be easily obtained, by placing the matras in no deeper in the sand than the surface of the matter contained in it; and removing a little of the sand from the sides of the glass, as soon as the flowers begin to appear in the neck; when the heat should likewise be somewhat low, and not at all raised during the whole process. The sublimation is known to be completed by the edges of the crystalline cake which will firm on the surface of the cap mortuum, appearing smooth and even, and a little removed from it.

Our apothecaries rarely, and few even of the chemists, attempt the making of this preparation themselves; greatest part of what is used among us comes from Venice and Holland. This foreign sublimate has been reported to be adulterated with arsenic. Some affirm, that this dangerous fraud may be discovered by the sublimate turning black on being moistened with alkaline ley; which by others is denied. As this point seemed of some importance to be determined, sundry experiments have been made with this view, which prove the insufficiency of alkalis for discovering arsenic. Alkaline ley, poured into a solution of pure arsenic, and into a mixture of the two solutions in different proportions, produced no blackness in any; and though

Preparations and Compositions.

though the pure sublimate, and the mixtures of it with arsenic, exhibited some differences in these trials, yet these differences were neither so constant nor so strongly marked as to be laid down universally for criteria of the presence or absence of arsenic; different specimens of sublimate, known to be pure, have been found to differ considerably in this respect; probably from their holding a little more or less mercury in proportion to the acid, or from their retaining some small portion of those acids which were employed in the preparation as intermedia.

Some chemists deny the practicability of this adulteration. There is a process common in books of chemistry, wherein sublimate and arsenic being mixed together, and set to sublime, do not arise in one mass, or yield any thing similar to the preparation here intended: the arsenic absorbs the acid of the sublimate, and is reduced thereby into a liquid or butyraceous consistence; while the mercury thus freed from the acid distils in its fluid form: if the quantity of arsenic be insufficient to decompose the whole of the sublimate, the remainder of the sublimate concretes distinct from the arsenical butter. From whence they conclude, that arsenic and sublimate cannot be united together into a crystalline cake, the form in which this preparation is brought to us.

The above experiment is not altogether decisive; for though arsenic and sulphur do not assume the required form by the common process it is possible they may by some other management. It will therefore be proper to point out means for the satisfaction of those who may be desirous of convincing themselves of the genuineness of this important preparation. Let some of the sublimate, powdered in a glass mortar, be well mixed with twice its weight of black flux, and a little filings or shavings of iron; put the mixture into a crucible capable of holding four or five times as much; give a gradual fire till the ebullition ceases, and then hastily increase it to a white heat. If no fumes of a garlic smell can be perceived during the process, and if the particles of iron retain their form without any of them being melted, we may be sure that the mixture contained no arsenic.

Sublimate is a most violent corrosive, soon corrupting and destroying all the parts of the body it touches. A solution of it in water, in the proportion of about a dram to a quart, is used for keeping down proud flesh, and cleansing foul ulcers; and a more diluted solution as a cathartic, and for destroying cutaneous insects. But a great deal of caution is requisite even in these external uses of it.

Some have nevertheless ventured to give it internally, in the dose of one-tenth or one-eighth of a grain, Boerhaave relates, that if a grain of it be dissolved in an ounce or more of water, and a dram of this solution, sweetened with syrup of violets, be taken twice or thrice a day, it will prove efficacious in many distempers though incurable; but be particularly cautious us not to venture upon it, unless the method of managing it be well known.

Sublimate dissolved in vinous spirit has of late been given internally in larger doses; from a quarter of a grain to half a grain. This method of using it was brought into repute by Baron Van Swieten at Vienna, especially for venereal maladies; and several trials of

it have also been made in this kingdom with success. Eight grains of the sublimate are dissolved in six or seven ounces of rectified spirit of wine or proof spirit; the rectified spirit dissolves it more perfectly, and seems to make the medicine milder in its operation than the proof spirit of the original prescription of Van Swieten. Of this solution from one to two spoonfuls, three or four, is, from half an ounce to an ounce, are given twice a day, and continued till all the symptoms are removed; observing to use a low diet, with plentiful dietion, otherwise the sublimate is apt to purge, and gripe severely. It generally purges more or less at the beginning, but afterwards seems to operate chiefly by urine and perspiration.

Sublimate consists of mercury united with a large quantity of marine acid. There are two general methods of destroying its corrosive quality, and rendering it mild: the one is, combining with it as much fresh mercury as the acid is capable of taking up; and the other by separating a part of the acid by means of alkaline salts and earths. On the first principle sweet mercury is formed; on the latter, white precipitate. But before entering on these, it is proper to give the following formula.

Solution of corrosive sublimate mercury. E.

Take of corrosive sublimate mercury, six grains; sal ammoniac, twelve grains. Dissolve in a pound of distilled water. If hard water be used for this purpose, the solution suffers a kind of decomposition from the nitrous selenite of the water.

The solution of corrosive sublimate in water is very much assisted by sal ammoniac. There was a practice some years ago, of mixing up this solution with wheat flour into the consistence of pills for internal use: and the quantity of sublimate in each pill was easily ascertained.

This solution may also be used for washing venereal and other sores; but in many instances it will be found too acrid for that purpose, and will require to be weakened by the addition of a portion of water.

Calomel. L.

Take of muriated quicksilver, one pound; purified quicksilver, nine ounces. Rub them together till the globules disappear, and then sublime the mass. In the same manner repeat the sublimation four times. Afterwards rub the matter into a very fine powder, and wash it by pouring on boiling distilled water.

Sweet mercury. E.

Take of corrosive mercury sublimate reduced to a powder in a glass mortar, four ounces; pure quicksilver, three ounces and a half. Mix them well together, by long trituration in a glass or marble mortar until the quicksilver ceases to appear. Put the powder into an oblong phial, of such a size that only one third of it may be filled; and set the glass in sand, that the mass may sublime. After the sublimation, break the glass; and the red powder which is found in its bottom, with the whitish one that sticks about the neck, being thrown away, let the white mercury be sublimed again three or four times, and reduce it to a very fine powder.

The trituration of corrosive sublimate with quicksilver is a very noxious operation: for it is almost impossible, by any care, to prevent the lighter particles of the former from rising so as to affect the operator's eyes and mouth. It is nevertheless of the utmost consequence, that the ingredients be perfectly united before the sublimation is begun. It is necessary to pulverize the sublimate before the mercury is added to it: but this may be safely performed with a little caution; especially if during the pulverization the matter be now and then sprinkled with a little spirit of wine: this addition does not at all impede the union of the ingredients, or prejudice the sublimation: it will be convenient not to close the top of the subliming vessel with a cap of paper at first (as is usually practised), but to defer this till the mixture begins to sublime, that the spirit may escape.

The rationale of this process deserves particular attention; and the more so, as a mistaken theory herein has been productive of several errors with regard to the operation of mercurials in general. It is supposed, that the *dulcification*, as it is called, of the corrosive mercury is owing to the spiculæ or sharp points, on which its corrosiveness depends, being broken and worn off by the frequent sublimations. If this opinion were just, the corrosive would become mild, without any addition, barely by repeating the sublimation; but this is contrary to all experience. The abatement of the corrosive quality of the sublimate is entirely owing to the combination of as much fresh mercury as is capable of being united with it; and by whatever means this combination be effected, the preparation will be sufficiently dulcified. Triture and digestion promote the union of the two, while sublimation tends rather to disunite them. The prudent operator, therefore, will not be solicitous about separating such mercurial globules as appear distinct after the first sublimation: he will endeavour rather to combine them with the rest, by repeating the triture and digestion.

The college of Wirtemberg require their sweet mercury to be only twice sublimed, and the Augustan but once; and Neumann proposes making it directly by a single sublimation from the ingredients of the corrosive sublimate, by only taking the quicksilver in a larger proportion.

Mr Selle of Berlin has lately proposed a method of making sweet mercury nearly similar to that of Neumann. He directs, that to four ounces of pure quicksilver there should be added as much strong vitriolic acid. These are to be mixed over a strong fire till they become a solid hard mass. This mass is to be trituated in a stone mortar with two ounces and an half of quicksilver and four ounces and an half of dried common salt. And by a single, or at most two, sublimations, he assures us an excellent sweet mercury is obtained.

If the medicine made after either of these methods should prove in any degree acrid, water boiled on it for some time will dissolve and separate that part in which its acrimony consists. The marks of the preparation being sufficiently dulcified are, its being perfectly insipid to the taste, and indissoluble by long boiling in water. Whether the water in which it has been boiled has taken up any part of it may be known by dropping into the liquor a ley of any fixed alkaline

salt, or any volatile alkaline spirit. If the decoction has any mercurial impregnation, it will grow turbid on this addition; it otherwise, it will continue limpid. But here care must be taken not to be deceived by any extraneous saline matter in the water itself. Most of the common spring waters turn milky on the addition of alkalis; and therefore, for experiments of this kind, distilled water or rain water ought to be used.

This name of *calomel*, though for a considerable time banished from our best pharmacopœias, is again restored by the London college. But we cannot help thinking, that they might easily have invented a name better expressing the constituent parts and nature of the preparation.

Calomel, or sweet mercury, may be considered as one of the most useful of the mercurial preparations; and it may be estimated as holding an intermediate place between the acetated quicksilver, one of the mildest of the saline preparations, and the muriated quicksilver, or corrosive sublimate, one of the most acrid of them.

Mild muriated quicksilver. L.

Take purified quicksilver, diluted nitrous acid, of each half a pound. Mix in a glass vessel, and set it aside until the quicksilver be dissolved. Let them boil, that the salt may be dissolved. Pour out the boiling liquor into a glass vessel into which another boiling liquor has been put before, consisting of sea-salt, four ounces; distilled water, eight pints. After a white powder has subsided to the bottom of the vessel, let the liquor swimming at the top be poured off, and the remaining powder be washed till it becomes insipid with frequent affusions of hot water; then dried on blotting paper with a gentle heat.

This preparation had a place in former editions of the London and Edinburgh pharmacopœias under the name of *mercurius dulcis precipitatus*. But the process as now given is somewhat altered, being that of Mr Scheele of Sweden, who has recommended this as an easy and expeditious method of preparing sweet mercury or calomel.

It appears from several tests that this precipitate is equal in every respect to that prepared by the preceding processes. It is less troublesome and expensive, and the operator is not exposed to the noxious dust arising from the triture of the quicksilver with the corrosive sublimate, which necessarily happens by the common method. The powder is also finer than can be made from the common sublimed sweet mercury by any trituration whatever. The clear liquor standing over the precipitate is a solution of cubic or rhomboidal nitre.

Sweet mercury, which may be considered as precisely the same with the calomel and mild muriated quicksilver, appears to be one of the best and safest preparations of this mineral, when intended to act as a quick and general stimulant. Many of the more elaborate processes are no other than attempts to produce from mercury such a medicine as this really is. The dose recommended by some for raising a salivation, is ten or fifteen grains taken in the form of a bolus or pill, every night or oftener, till the ptyalism begins. As an alterant and diaphoretic, it has been given in doses of five or six grains; a purgative being occasionally

Preparations and Compositions.

tionally interposed, to prevent its affecting the mouth. It answers, however, much better when given in smaller quantities, as one, two, or three grains every morning and evening, in conjunction with such substances as determine its action to the skin, as the extract of resin of guaiacum; the patient at the same time keeping warm, and drinking liberally of warm diluent liquors. By this method of managing it, obstinate cutaneous and venereal distempers have been successfully cured without any remarkable increase of the sensible evacuations. It is sometimes, however, difficult to measure its effects in this way; and it is very apt to run off by the intestines, that we can seldom administer it in such a manner as to produce those permanent effects which are often required, and which we are able to do by other preparations. It has been lately proposed to rub the gums and inside of the mouth with this preparation, as a ready and effectual method of producing salivation. This practice has been particularly recommended in the internal hydrocephalus, where it is exceedingly difficult to excite a salivation, by other means. The advantages of this practice are not fully confirmed by experience: and when mercury is attended with advantage in hydrocephalus, this is not probably the consequence of any discharge under the form of salivation, but merely of the mercury being introduced into the system in an active state, and thus promoting absorption. And salivation when it arises from the internal use of mercury, may be considered as the strongest test of this; but this is by no means the case when salivation arises from a topical action on the excretories of saliva.

Red nitrated quicksilver. L.

- 295 Take of purified quicksilver, nitrous acid, each one pound; muriatic acid, one dram. Mix in a glass vessel, and dissolve the quicksilver in a sand bath; then raise the fire until the matter be formed into red crystals.

Red corrosive commonly called red precipitated mercury. E.

- 296 Take of quicksilver, weak nitrous acid, each one pound. Let the quicksilver be dissolved in the acid, and then let the solution be evaporated to a white dry mass. This being beat into a powder, must be put into a glass retort, and subjected to a fire gradually increased, till a small quantity of it, taken out in a glass spoon, and allowed to cool, assumes the form of shining red squamæ. Let the vessel be then removed from the fire. During the process the matter must be carefully agitated by a glass rod, that it may be equally heated.

The marine acid in the menstruum ordered in the first process dissolves the mercurial calx to assume the bright sparkling look admired in it; which, though perhaps no advantage to it as a medicine, ought nevertheless to be insisted on by the buyer as a mark of its goodness and strength. As soon as the matter has gained this appearance, it should be immediately removed from the fire; otherwise it will soon lose it again. The preparation of this red precipitate, as it is called, in perfection, is supposed by some to be a secret not known to our chemists, inasmuch that we are under the necessity of importing it from abroad. This reflection seems to be founded on misinformation.

We sometimes indeed receive considerable quantities of it from Holland: but this depends on the ingredients being commonly cheaper there than with us, and not on any secret in the manner of the preparation.

Preparations and Compositions.

This precipitate is, as its title imports, an eschrotic; and with this intention is frequently employed by the surgeons with balsicum and other dressings, for consuming fungous flesh in ulcers and the like purposes. It is subject to great uncertainty in point of strength, more or less of the acid exhaling according to the degree and continuance of the fire. The best criterion of its strength, as already observed, is its brilliant appearance: which is also the mark of its genuineness: if mixed with minium, which it is sometimes said to be, the duller hue will discover the abuse. This admixture may be more certainly detected by means of fire: the mercurial part will totally evaporate, leaving the minium behind.

Some have ventured to give this medicine internally in venereal, scrophulous, and other obstinate chronic disorders, in doses of two or three grains or more. But certainly the milder mercurials, properly managed, are capable of answering all that can be expected from this; without occasioning violent anxieties, tormina of the bowels, and similar ill consequences, which the best management can scarcely prevent this corrosive preparation from sometimes inducing. The chemists have contrived sundry methods of correcting and rendering it milder, by divesting it of a portion of the acid: but to no very good purpose, as they either leave the medicine still too corrosive, to render it similar to others which are procurable at an easier rate.

White calx of quicksilver. L.

- Take of muriated quicksilver, sal ammoniac, water of kali, each half a pound. Dissolve first the sal ammoniac, afterwards the muriatic quicksilver in distilled water, and add the water of kali. Wash the precipitated powder until it becomes insipid.

White precipitate of mercury. E.

- 298 Dissolve corrosive sublimate mercury in a sufficient quantity of hot water, and gradually drop into the solution some spirit of sal ammoniac as long as any precipitation ensues. Wash the precipitated powder with several fresh quantities of warm water.

These preparations are used chiefly in ointments, with which intention their fine white colour is no small recommendation to them. For internal purposes they are rarely employed, nor is it at all wanted; they are nearly similar to sweet mercury, but less certain in their effects.

Though the processes directed by the London and Edinburgh colleges be here somewhat different, yet the preparations are ultimately the same. The process described by the Edinburgh college is the most simple but is liable to some objections.

Corrosive sublimate, as we have already seen, consists of mercury united with a large portion of acid. It is there dulcified by adding as much fresh mercury as is sufficient to saturate all the acid; here, by separating all the acid that is not saturated. This last way seems an unfrugal one, on account not only of the loss of the acid, but of the volatile spirit necessary for absorbing it. The operator may, however, if it should be thought

thought worth while, recover the volatile salt from the liquor, by adding to it, after the precipitate has been separated, a proper quantity of potash, and distilling with a gentle heat, in the same manner as for the spirit of volatile salt of sal ammoniac; for a true sal ammoniac is regenerated, in the precipitation, from the union of the volatile spirit with the marine acid of the sublimate. It is by no means advisable to use the liquor itself as a solution of sal ammoniac, or to separate the sal ammoniac from it by evaporation and crystallization, as a part of the mercury might be retained, and communicate dangerous qualities: but the volatile salt separated by distillation may be used without fear of its containing any mercury; none of which will arise with the heat by which the volatile salts are distilled.

Fixed alkalis answer as effectually for precipitating solutions of sublimate as the volatile; but the precipitate obtained by means of the former, instead of being white, as with the latter, is generally of a reddish yellow or orange colour. If sal ammoniac be dissolved along with the sublimate, the addition of fixed alkalis will, by extricating the volatile alkali of the sal ammoniac, occasion as white a precipitation as if the volatile salt had been previously separated and employed in its pure state; and this compendium is now allowed by the London college in the process which they have adopted.

There the sal ammoniac, besides its use in the capital intention, to make a white precipitation, promotes the solution of the sublimate; which of itself is difficultly, and scarcely at all totally, soluble by repeated boiling in water: for however skilfully it be prepared, some part of it will have an under proportion of acid, and consequently approach to the state of sweet mercury. A good deal of care is requisite in the precipitation; for if too large a quantity of the fixed alkaline solution be imprudently added, the precipitate will lose the elegant white colour for which it is valued.

Quicksilver with sulphur. L.

- 299 Take of purified quicksilver, flowers of sulphur, each one pound. Rub them together until the globules disappear.

Æthiops mineral. E.

- 300 Take of quicksilver, flowers of sulphur, each equal weights. Grind them together in a glass or stone mortar, with a glass pestle, till the mercurial globules totally disappear.
An æthiops is made also with a double quantity of mercury.

We need hardly remark, that these preparations, though now differing in name, are in reality the same. Nor need we add, that the direction given by the Edinburgh college, of using a glass or stone mortar and pestle, is necessary and proper.

The union of the mercury and sulphur might be much facilitated by the assistance of a little warmth. Some are accustomed to make this preparation in a very expeditious manner, by melting the sulphur in an iron balle, then adding the quicksilver, and stirring them together till the mixture be completed. The small degree of heat here sufficient cannot reasonably be supposed to do any injury to substances which have

already undergone much greater fires, not only in the extraction from their ores, but likewise in the purifications of them directed in the pharmacopœia. In the following process they are exposed in conjunction to a strong fire, without suspicion of the compound receiving any ill quality from it. 'Tis much is certain, that the ingredients are more perfectly united by heat than by the degree of triture usually bestowed on them. From the æthiops prepared by triture, part of the mercury is apt to be squeezed out on making it into an electuary or pills; from that made by fire no separation is observed to happen.

Æthiops mineral is one of the most inactive of the mercurial preparations. Some practitioners, however, have represented it as possessing extraordinary virtues; and most people imagine it a medicine of some efficacy. But what benefit is to be expected from it in the common doses of eight or ten grains, or a scruple, may be judged from hence, that it has been taken in doses of several drams, and continued for a considerable time, without producing any remarkable effect. Sulphur eminently abates the power of all the more active minerals, and seems to be at the same time restrained by them from operating in the body itself. Boerhave, who is in general sufficiently liberal in the commendation of medicines, disapproves of the æthiops in very strong terms. "It cannot enter the absorbent vessels, the lacteals, or lymphatics, but passes directly through the intestinal tube, where it may happen to destroy worms, if it operates luckily. They are deceived who expect any other effects from it; at least I myself could never find them. I am afraid it is unwarily given, in such large quantities, to children, and persons of tender constitutions, as being a foreign mass, unconquerable by the body; the more to be suspected as it there continues long sluggish and inactive. It does not raise a salivation, because it cannot come into the blood. Who knows the effects of a substance, which, so long as it remains compounded, seems no more active than any ponderous insipid earth?" The æthiops, with a double proportion of mercury, now received into our pharmacopœias, has a greater chance for operating as a mercurial; and probably the quantity of mercury might be still further increased to advantage.

Red sulphurated quicksilver. L.

Take of quicksilver, purified, forty ounces; sulphur, eight ounces. Mix the quicksilver with the melted sulphur; and if the mixture takes fire, extinguish it by covering the vessel; afterwards reduce the mass to powder, and sublime it.

It has been customary to order a larger quantity of sulphur than here directed; but smaller proportions answer better, for the less sulphur the finer coloured is the cinnabar.

As soon as the mercury and sulphur begin to unite, a considerable explosion frequently happens, and the mixture is very apt to take fire, especially if the process be somewhat hastily conducted. This accident the operator will have previous notice of, from the matter swelling up, and growing suddenly confident: as soon as this happens, the vessel must be immediately close covered.

During the sublimation, care must be had that the matter

Prepara-
tions and
Composi-
tions.

matter rise not in to the neck of the vessel, so as to block up and burst the glass. To prevent this, a wide-necked bolt head, or rather an oval earthen jar, coated, should be chosen for the subliming vessel. If the former be employed, it will be convenient to introduce at times an iron wire, somewhat heated, in order to be the better assured that the passage is not blocking up; the danger of which may be prevented by cautiously raising the vessel higher from the fire.

If the ingredients were pure, no feces will remain: in such cases, the sublimation may be known to be over by introducing a wire as before, and feeling therewith the bottom of the vessel, which will then be perfectly smooth: if any roughness or inequalities are perceived, either the mixture was impure, or the sublimation is not completed: if the latter be the case, the wire will soon be covered over with the rising cinnabar.

The preparers of cinnabar in large quantity employ earthen jars, which in shape pretty much resemble an egg. These are of different size, according to the quantity intended to be made at one sublimation, which sometimes amounts to two hundred weight. The jar is usually coated from the small end almost to the middle, to prevent its breaking by the vehemence or irregularity of the fire. The greater part, which is placed uppermost, not being received within the furnace, has no occasion for this defence. The whole secret with regard to this process, is the management of the fire, which should be so strong as to keep the matter continually subliming to the upper part of the jar, without coming out at its mouth, which is covered with an iron plate; care should also be taken to put into the subliming vessel only small quantities of the mixture at a time.

The principal use of cinnabar is as a pigment. It was formerly held in great esteem as a medicine in cutaneous foulnesses, gouty and rheumatic pains, epileptic cases, &c. but of late it has lost much of its reputation. It appears, to be nearly similar to the æthiops already spoken of. Cartheiser relate, that having given cinnabar in large quantities to a dog, it produced no sensible effect, but was partly voided along with the feces unaltered, and partly found entire in the stomach and intestines on opening the animal. The celebrated Frederic Hoffman, after bestowing high encomium on this preparation, as having in many instances within his own knowledge perfectly cured epilepsies and vertigoes from contusions of the head (where it is probable, however, that the cure did not so much depend on the cinnabar as on the spontaneous recovery of the parts from the external injury), observes, that the large repeated doses, necessary for having any effect, can be borne only where the first passages are strong; and that if the fibres of the stomach and intestines are lax and flaccid, the cinnabar accumulated and concreting with the mucous matter of the parts, occasions great oppression; which seems to be an acknowledgement that the cinnabar is not subdued by the powers of digestion, and has no proper medicinal activity. There are indeed some instances of the daily use of cinnabar having brought on a salivation; perhaps from the cinnabar, used in those cases, having contained a less proportion of sulphur than the sorts commonly met with. The regulus of antimony, and even white ar-

fenic when combined with a certain quantity of common sulphur, seem to have their detestous power destroyed: on separating more and more of the sulphur, they exert more and more of their proper virulence. It does not seem unreasonable to presume, that mercury may have its activity varied in the same manner; that when perfectly satiated with sulphur, it may be inert: and that when the quantity of sulphur is more and more lessened, the compound may have greater and greater degrees of the proper efficacy of mercurials.

Cinnabar is sometimes used in fumigations against venereal ulcers in the nose, mouth, and throat. Half a dram of it burnt, the fume being imbibed with the breath, has occasioned a violent salivation. This effect is by no means owing to the medicine as cinnabar: when set on fire, it is no longer a mixture of mercury and sulphur, but mercury resolved into fume, and blended in part with the volatile vitriolic acids; in either of which circumstances this mineral as we have already observed, has very powerful effects.

Vitriolated quicksilver. L.

Take of quicksilver, purified, vitriolic acid, each one pound. Mix in a glass vessel, and heat them by degrees until they unite into a white mass, which is to be perfectly dried with a strong fire. This matter, on the affusion of a large quantity of hot distilled water, immediately becomes yellow, and falls to powder. Rub the powder carefully with this water in a glass mortar. After the powder has subsided, pour off the water; and, adding more distilled water several times, wash the matter till it become insipid.

Yellow mercury commonly called Turbith mineral. E.

Take of quicksilver, four ounces; vitriolic acid, eight ounces. Carefully mix them together and distil in a retort, placed in a sand furnace, to dryness: the white calx, which is left at the bottom, being ground to powder, must be thrown into warm water. It immediately assumes a yellow colour, but must afterwards be purified by repeated ablutions.

The quantity of oil of vitriol, formerly directed, was double to that now employed by the Edinburgh college. The reduction made in this article greatly facilitates the process; and the proportions of the London college are perhaps preferable.

Boerhaave directs this preparation to be made in an open glass, slowly heated, and then placed immediately on burning coals; care being taken to avoid the fumes, which are extremely noxious. This method will succeed very well with a little address when the ingredients are in small quantity; but where the mixture is large, it is better to use a retort, placed in a sand furnace, with a recipient, containing a small quantity of water, luted to it. Great care should be taken, when the oil of vitriol begins to bubble, that the heat be steadily kept up, without at all increasing it, till the ebullition ceases, when the fire should be augmented to the utmost degree, that as much as possible of the redundant acid may be expelled.

If the matter be but barely efficated, it proves a caudic salt, which in the ablution with water will almost all dissolve, leaving only a little quantity of turbith:

Prepara-
tions and
Composi-
tions.

302

303

With the more of the acid that has been dissipated, the less of the remaining mercury will dissolve, and consequently the yield of turbith will be greater; fire expelling only such part of the acid as is not completely saturated with mercury, while water takes up always, along with the acid, a proportional quantity of the mercury itself. Even when the matter has been strongly calcined, a part will still be soluble; this evidently appears on pouring into the washings a little solution of fixed alkaline salt, which will throw down a considerable quantity of yellow precipitate, greatly resembling the turbith, except, that it is less violent in operation.

From this experiment it appears, that the best method ofedulcorating this powder is, by impregnating the water, intended to be used in its ablution, with a determined proportion of fixed alkaline salt; for by this means, the washed turbith will not only turn out greater in quantity, but, what is of more consequence, will have an equal degree of strength; a circumstance, which deserves particularly to be considered, especially in making such preparations as, from an error in the process, may prove too violently corrosive to be used with any tolerable degree of safety. It is necessary to employ warm water if we are anxious for a fine colour. If cold water be used, the precipitate will be white.

It is observable, that though the superfluous acid be here absorbed from the mercury by the alkaline salt; yet in some circumstances this acid forsakes that salt to unite with mercury. If vitriolated tartar, or *vitriolated kali*, as it is now called, which is a combination of vitriolic acid with fixed alkali, be dissolved in water, and the solution added to a solution of mercury in aquafortis, the vitriolic acid will unite with the mercury, and form with it a turbith, which falls to the bottom; leaving only the alkali dissolved in the aquafortis, and united with its acid into a regenerated nitre. On this principle depends the preparation described by Wilson under the title of *an excellent precipitate of mercury*: which is no other than a true turbith, though not generally known to be such. It is made by dissolving four ounces of vitriolated kali in sixteen ounces of spirit of nitre; dissolving in this compound liquor four ounces of mercury; abstracting the menstruum by a sand heat; andedulcorating with water the gold coloured mass which remains.

Turbith mineral is a strong emetic, and with this intention operates the most powerfully of all the mercurials that can be safely given internally. Its action, however, is not confined to the prime viæ; it will sometimes excite a salivation, if a purgative be not taken soon after it. This medicine is used chiefly in virulent gonorrhœas, and other venereal cases, where there is a great flux of humours to the parts. Its chief use at present is in swellings of the testicle from a venereal affection; and it seems not only to act as a mercurial, but also, by the severe vomiting it occasions, to perform the office of a discutient, by accelerating the motion of the blood in the parts affected. It is said likewise to have been employed with success, in robust constitutions, against leprous disorders and obstinate glandular obstructions: the dose is from two grains to six or eight. It may be given in doses of a grain or two as an alterative and diaphoretic, in the same manner as the calcined mercury already spoken

of. Dr Hope has found that the turbith mineral is the most convenient emetic he has had occasion to employ.

This medicine was lately recommended as the most effectual preservative against the hydrophobia. It has been alledged there are several examples of its preventing madness in dogs which had been bitten: and some of its performing a cure after the madness was begun: from six or seven grains to a scruple may be given every day, or every second day, for a little time, and repeated at the two or three succeeding fulls and changes of the moon. Some few trials have likewise been made on human subjects bitten by mad dogs; and in these also the turbith, used either as an emetic or alterative, seemed to have good effects.

The washings of turbith mineral are used by some externally for the cure of the itch and other cutaneous foulnesses. In some cases mercurial lotions may be proper, but they are always to be used with great caution: this is by no means an eligible one, as being extremely unequal in point of strength, more or less of the mercury being dissolved, as has been observed above, according to the degree of calcination. The pharmacopœia of Paris directs a mercurial wash free from this inconvenience, under the title of *Aqua mercurialis*, or *Mercurius liquidus*. It is composed of one ounce of mercury, dissolved in a sufficient quantity of spirit of nitre, and diluted with 30 ounces of distilled water. In want of distilled water, rain water may be used: but of spring waters there are very few which will mix with the mercurial solution without growing turbid and precipitating a part of the mercury.

Simple mercurial solution. Jos. Jac. Plenck.

Take of purest quicksilver, one dram; gum arabic, two drams. Beat them in a stone mortar, adding by little and little distilled water of fumitory till the mercury thoroughly disappear in the mucilage. Having beat and mixed them thoroughly, add by degrees, and at the same time rubbing the whole together, syrup of kermes, half an ounce, distilled water of fumitory, eight ounces.

304

This mixture was much celebrated by its author as an effectual preparation of mercury, unattended with the inconvenience of producing a salivation; and he imagined that this depended on a peculiar affinity existing between mercury and mucilage. Hence such a conjunction, the gummy quicksilver, as it has been styled, has been the foundation of mixtures, pills, syrups, and several other formulæ, which it is unnecessary to dwell upon in this place.

By a long continued triture, mercury seems to undergo a degree of calcination; at least its globular appearance is not to be discerned by the best microscope; its colour is converted into that of a greyish powder; and from the inactive substance in its globular form, it is now become one of the most powerful preparations of this metallic body. The use of the gum seems to be nothing more than to afford the interposition of a viscid substance to keep the particles at a distance from each other, till the triture requisite to produce this change be performed. Dr Saunders has clearly proved, that no real solution takes place in this

this

this process, and that though a quantity of mercurial particles are still retained in the mixture after the globular parts have been deposited by dilution with water, yet that this suspended mercurial matter is only diffused in the liquor, and capable of being perfectly separated by filtration. That long triture is capable of effecting the above change on mercury, is fully evinced from the well known experiment of Dr Boerhaave, in producing a kind of calcined mercury by exposing quicksilver inclosed in a phial to the agitation produced by keeping the phial tied to a wind-mill for 14 years. By inclosing a pound of quicksilver in an iron box, with a quantity of iron nails and a small quantity of water, by the addition of which a greater degree of intestine motion is given to the particles of the mercury, and fixing the box to the wheel of a carriage, Dr Saunders obtained, during a journey of 400 miles, two ounces of a greyish powder, or calx of mercury.

On the above accounts we are not to ascribe the effects of Plenck's solution to an intimate division of the globules of mercury, nor to any affinity, nor elective attraction, between gum-arabic and mercury; which last Mr Plenck has very unphilosophically supposed. The same thing can be done by means of gum-tragacanth, by honey, and by fundry balsams. It is evidently owing to the conversion of the quicksilver to a calciform nature; but as this will be accomplished more or less completely according to the different circumstances during the triture, it is certainly preferable, instead of Plenck's solution, to diffuse in mucilage, or other viscid matters, a determinate quantity of the ash-coloured powder, or other calx of mercury.

It is proper to take notice, that there is in many instances a real advantage in employing mucilaginous matters along with mercurials, these being found to prevent diarrhoea and salivation to a remarkable degree. So far, then, Mr Plenck's solution is a good preparation of mercury, though his chemical rationale is perhaps erroneous. The distilled water and syrup are of no consequence to the preparation, either as facilitating the process or for medicinal use.

It is always most expeditious to triturate the mercury with the gum in the state of mucilage. Dr Saunders found that the addition of honey was an excellent auxiliary; and the mucilage of gum-tragacanth seems better suited for this purpose than gum-arabic.

CHAP. XIV. Preparations of Lead.

365

LEAD readily melts in the fire, and calcines into a dusky powder; which, if the flame is reverberated on it, becomes at first yellow, then red, and at length melts in a vitreous mass. This metal dissolves easily in the nitrous acid, difficultly in the vitriolic, and in small quantity in the vegetable acids; it is also soluble in expressed oil, especially when calcined.

Lead and its calces, while undissolved, have no considerable effects as medicines. Dissolved in oils, they are supposed to be (when externally applied) anti-inflammatory and desiccative. Combined with vegetable acids, they are remarkably so; and taken internally prove a powerful though dangerous styptic.

VOL. XIV.

There are two preparations of lead, *red* and *white* lead, as they are commonly called, which are much more extensively employed in other arts than in medicine, and of course they are prepared in large quantities. These formerly stood among the preparations in our pharmacopœias; but they are now referred to the materia medica. We shall not, therefore, on the present occasion, make any farther observations with respect to them, but shall here insert from the old editions of the Edinburgh pharmacopœia the directions there given for preparing them.

Red lead.

Let any quantity of lead be melted in an unglazed earthen vessel, and kept stirring with an iron spatula till it falls into powder, at first blackish, afterwards yellow, and at length of a deep red colour, in which last state it is called *minium*; taking care not to raise the fire so high as to run the calx into a vitreous mass.

The preparation of red lead is so troublesome and tedious, as scarce ever to be attempted by the apothecary or chemist; nor indeed is this commodity expected to be made by them, the preparation of it being a distinct branch of business. The makers melt large quantities of lead at once, upon the bottom of a reverberatory furnace built for this purpose, and so contrived that the flame acts on a large surface of the metal, which is continually changed by means of iron rakes drawn backwards and forwards, till the fluidity of the lead is destroyed; after which, the calx is only now and then turned. By barely stirring the calx, as above directed, in a vessel over the fire, it acquires no redness; the reverberation of flame on the surface being absolutely necessary for this effect. It is said, that 20 pounds of lead gain, in the process, five pounds; and that the calx, being reduced into lead again, is found one pound less than the original weight of the metal.

These calces are employed in external applications, for abating inflammations, cleansing and healing ulcers, and the like. Their effects, however, are not very considerable; nor are they perhaps of much farther real use, than as they give confidence to the plaster, unguent, &c.

Ceruse or white lead.

Put some vinegar into the bottom of an earthen vessel, and suspend over the vinegar very thin plates of lead, in such a manner that the vapour which arises from the acid may circulate about the plates. Set the containing vessel in the heat of horse-dung for three weeks; if at the end of this time the plates be not totally calcined, scrape off the white powder, and expose them again to the steam of vinegar, till all the lead be thus corroded into powder.

The making of white lead is also become a trade by itself, and confined to a few persons, who have large conveniences for this purpose. The general method which they follow is nearly the same with that above described. See the Philosophical Transactions, n^o 137.

In this preparation, the lead is so far opened by the acid, as to discover, when taken internally, the

3 A

na-

366

367

Preparations and Compositions.

malignant quality of the metal; and to prove externally, when sprinkled on running sores, or ulcers moderately cooling, drying, and astringent.

Acetat. J. ceruse. L.

- 308 Take of ceruse, one pound; distilled vinegar, one gallon and an half. Boil the ceruse with the vinegar until the vinegar is saturated; then filter thro' paper; and, after proper evaporation, set it aside to crystallize.

Salt, commonly called sugar of lead. E.

- 309 Put any quantity of ceruse, into a cucurbit, and pour upon it ten times its quantity of distilled vinegar. Let the mixture stand upon warm sand till the vinegar becomes sweet; when it is to be poured off, and fresh vinegar added as often as it comes off sweet. Then let all the vinegar be evaporated in a glass vessel to the consistence of pretty thin honey, and set it aside in a cold place, that crystals may be formed, which are to be afterwards dried in the shade. The remaining liquor is again to be evaporated, that new crystals may be formed; the evaporation of the residuous liquor is to be repeated till no more crystals concreate.

Ceruse (especially that sort called *flake lead*, which is not, like the others, subject to adulteration) is much preferable either to minium or litharge, for making the sugar of lead: for the corrosion which it has undergone from the steam of the vinegar disposes it to dissolve more readily. It should be finely powdered before the vinegar be put to it; and during the digestion, or boiling, every now and then stirred up with a wooden spatula, to promote its dissolution, and prevent its concreting into a hard mass at the bottom. The strong acid obtained from the *caput mortuum* of vinegar may be employed for this purpose to better advantage than the weaker, though purer acid, above directed. If a small quantity of rectified spirit of wine be prudently added to the solution as soon as it is duly exhaled, and the mixture suffered to grow cold by slow degrees, the sugar will concreate into very large and transparent crystals, which are scarcely to be obtained by any other method.

If the crystals be dried in sunshine, they acquire a blackish or livid colour. This seems to happen from the absorption of light and its conversion into phlogiston. If it be owing to the escape of pure air, why are the rays of the sun necessary to this discharge? On whatever principles we account for it the fact is the same; that the crystals soon lose their saline condition and the lead gradually re-assumes its metallic form. From this property of lead readily absorbing phlogiston, or parting with pure air, a solution of the sugar of lead becomes a very convenient sympathetic ink; (on the same grounds it is also used for a more important purpose. As lead communicates a sweetness and astringency very similar to the product of the vinous fermentation, a practice formerly prevailed among fraudulent dealers, of correcting the too great sharpness of acid wines by adulterating them with this metal. The abuse may be detected in two different ways: a piece of paper may be moistened with the liquor to be examined, and then exposed to

the vapours of liver of sulphur; the moistened paper will become of a livid colour, and this will happen though 200 or 300 leaves of a book were interposed between the paper and the vapours; by this method, then, we make a kind of sympathetic ink. But the best way of making the test is, to drop a small quantity of a solution of the liver of sulphur into the suspected liquor: if there be any lead present, this addition will instantly occasion the precipitation of a livid or dark coloured cloud.

The sugar of lead is much more efficacious than the foregoing preparations, in answering the several intentions to which they are applied. Some have ventured upon it internally, in doses of a few grains, as a styptic in hæmorrhagies, profuse colliquative sweats, seminal fluxes, the fluxus albus, &c. nor has it failed their expectations. It very powerfully restrains the discharge; but almost as certainly as it does this, it occasions symptoms of another kind, often more dangerous than those removed by it, and sometimes fatal. Violent pains in the bowels or through the whole body, and obstinate constipations, sometimes immediately follow, especially if the dose has been considerable: cramps, tremors, and weakness of the nerves, generally sooner or later ensue.

Boerhaave is of opinion, that this preparation proves malignant only as far as its acid happens to be *absorbed* in the body: for in such a case, he says, "it returns again into ceruse, which is violently poisonous."

On this principle it would follow, that in habits where acids abound, the sugar of lead would be innocent. But this is far from being the case. Lead and its preparation act in the body only when they are combined with acid: ceruse possesses the qualities of the saccharum only in a low degree; and either of them freed from the acid has little, if any, effect at all. For the same reasons, the salt of lead is preferable to the pompous *extract* and *vegeto-mineral water* of Goulard, in which the lead is much less perfectly combined in a saline state. It is sometimes convenient to assist the solution of the sugar of lead in water, by adding a portion of vinegar. The effects of the external application of lead seems to differ from the strength of the solution: thus a very weak solution seems to diminish directly the action of the vessels, and is therefore more peculiarly proper in active inflammations, as of the eyes; whereas a strong solution operates as a direct stimulant, and is therefore more successful in passive ophthalmia.

Water of acetated litharge. L.

Take of litharge, two pounds and four ounces; distilled vinegar, one gallon. Mix, and boil to six pints, constantly stirring; then set it aside. After the feces have subsided, strain.

This preparation may be considered as nearly the same with the extract and vegeto-mineral water of Mr Goulard. And it is probably from the circumstances of his preparations having come into a common use, that the London college have given this article a place in their pharmacopœa. It may, however, be a matter of doubt whether it be really intended to a place. For, as we have already observed, every purpose to be answered by it may be better obtained from the employment

Preparations and Compositions.

ployment of a solution of the acetated ceruse in simple water. The acetated water of litharge is intended for external use only.

CHAP. XV. *Preparations of tin.*

311 TIN easily melts in the fire, and calcines into a dusky powder; which, by a farther continuance of the heat, becomes white. A mass of tin heated till it be just ready to melt proves extremely brittle, so as to fall in pieces from a blow; and by dexterous agitation, into powder. Its proper menstruum is aqua-regia; though the other mineral acids may also be made to dissolve it, and the vegetable ones in small quantity. It crystallizes with the vegetable and vitriolic acids; but with the others, deliquesces.

The virtues of this metal are little known. It has been recommended as an antihysteric, antihæstic, &c. At present it is chiefly used as an anthelmintic.

Powdered tin. L.

312 Take of tin, six pounds. Melt it in an iron vessel, and stir it with an iron rod until a powder floats on the surface. Take off the powder, and, when cold, pass it through a sieve.

This preparation may be considered as nearly the same with the calx Jovis, which had a place in the former editions of the Edinburgh pharmacopœia: but from the late editions the calx has been expunged, and the filings or powder of tin, has a place only in their list of the materia medica. But although seldom prepared by the apothecary himself, it is not unfrequently employed as a remedy against worms, particularly the flat kinds, which too often elude the force of other medicines. The general dose is from a scruple to a dram; some confine it to a few grains. But Dr Alston assures us in the Edinburgh Essays, that its success chiefly depends on its being given in much larger quantities; he directs an ounce of the powder on an empty stomach, mixed with four ounces of molasses; next day, half an ounce; and the day following, half an ounce more; after which a cathartic is administered: he says the worms are usually voided during the operation of the purge, but that pains in the stomach occasioned by them are removed almost immediately upon taking the first dose of the tin.

This practice is sometimes successful in the expulsion of tænia, but by no means so frequently as Dr Alston's observations would lead us to hope.

Amalgama of tin. Dan.

313 Take of shavings of pure tin, two ounces; pure quick silver, three drams. Let them be rubbed to a powder in a stone mortar.

Some have imagined that tin thus acted on by mercury is in a more active condition than when exhibited in a state of powder; and accordingly it has been given in worm cases. But as both are equally insoluble in the animal fluids, this is not to be expected; and to obtain any peculiar properties which tin may possess to their full extent, it will probably be necessary to exhibit it in some saline state.

CHAR. XVI. *Preparations of zinc and copper.*

Calced zinc. L.

TAKE of zinc, broken into small pieces, eight ounces. Cast the pieces of zinc, at several times, into an ignited, large, and deep crucible, placed leaning, or half upright, putting on it another crucible in such a manner that the air may have free access to the burning zinc. Take out the calx as soon as it appears, and separates its white and lighter part by a fine sieve.

Flowers of zinc. E.

Let a large crucible be placed in a furnace, in an inclined situation, only half-upright; when the bottom of the vessel is moderately red, put a small piece of zinc, about the weight of two drams, into it. The zinc soon flames, and is at the same time converted into a spongy calx, which is to be raked from the surface of the metal with an iron spatula, that the combustion may proceed the more speedily: when the zinc ceases to flame, take the calx out of the crucible. Having put in another piece of zinc, the operation may be repeated as often as you please. Lastly, the calx is to be prepared like antimony.

These flowers, as used externally, are preferable for medicinal purposes to tutty, and the more impure sublimes of zinc, which are obtained in the brass works; and likewise to calamine, the natural ore of this metal, which contains a large quantity of earth, and frequently a portion of heterogeneous metallic matter. But besides being applied externally, they have also of late been used internally. The flowers of zinc, in doses from one to seven or eight grains, have been much celebrated of late years in the cure of epilepsy and several spasmodic affections; and there are sufficient testimonies of their good effects, where tonic remedies in those affections are proper.

White vitriol. E.

TAKE of zinc, cut into small pieces, three ounces; vitriolic acid, five ounces; water, twenty ounces; having mixed the acid and water, add the zinc, and when the ebullition is finished strain the liquor: then after proper evaporation set it apart in a cold place, that that it may shoot into crystals.

This salt is an elegant white vitriol. It differs from the common white vitriol, and the salt of vitriol of the shops, only in being purer, and perfectly free from any admixture of copper, or such other foreign metallic bodies as the others generally contain.

Purified vitriolated zinc. L.

TAKE of white vitriol, one pound; vitriolic acid, one dram; boiling distilled water, three pints. Mix, and filter through paper. After a proper evaporation, set it aside in a cold place to crystallize.

Although the Edinburgh college have given a formula for the preparations of white vitriol, yet their direction is very rarely followed by any of the apothecaries or chemists, who in general purchase it as obtained from the Goslar mines. When, however, it is got in this way, it is often a very impure salt, and re-

quires that purification which is here directed, and which is by no means necessary for the white vitriol artificially prepared, in the manner above directed. But by this process, the ordinary white vitriol, in its common state of impurity, will be freed from those impregnations of earthy and other matters which it often contains. And in this purified state it answers many useful purposes, not only externally but internally; and particularly in doses from ten grains to half a dram, it operates almost instantly as an emetic, and is at the same time perfectly safe. By employing it internally in smaller doses, we may obtain, and perhaps even more effectually, all the tonic power of the zinc; and some think it in every case preferable to the calx of zinc.

Ammoniacal copper. E.

- 318 Take of blue vitriol, two parts: volatile sal ammoniac, three parts; rub them together in a glass mortar, until they unite, after the effervescence ceases, into a uniform violet-coloured mass, which must be first dried on blotting paper, and afterwards by a gentle heat. The product must be kept in a glass phial, well closed with a glass stopper.

This preparation has been thought serviceable in epilepsies; but from its frequent want of success, and the disagreeable consequences with which its use is sometimes attended, it has not lately been much prescribed. It is employed by beginning with doses of half a grain, twice a day, and increasing them gradually to as much as the stomach will bear. Dr Cullen sometimes increased the dose to five grains.

CHAP. XVII. *Simple distilled waters. L. E.*

- 319 THE effluvia which exhale into the air from many vegetables, particularly from those of the odorous kind, consist apparently of principles of great subtilty and activity, capable of strongly and suddenly affecting the brain and nervous system, especially in those whose nerves are of great sensibility; and likewise of operating in a slower manner on the system of the grosser vessels. Thus Boerhaave observes, that in hysterical and hypochondriacal persons, the fragrant odour of the Indian hyacinth excites spasms, which the strong scent of rue relieves; that the effluvia of the walnut-tree occasions headaches, and makes the body costive; that those of poppies procure sleep; and that the smell of bean-blossoms, long continued, disorders the senses. Lemery relates, from his own knowledge, that several persons were purged by staying long in a room where damask roses were drying.

Some of the chemists have indulged themselves in the pleasing survey of these presiding spirits, as they are called, of vegetables; their peculiar nature in the different species of plants; their exhalation into the atmosphere by the sun's heat, and dispersion by winds; their rendering the air of particular places medicinal, or otherwise, according to the nature of the plants that abound. They have contrived also different means for collecting these fugitive emanations, and concentrating and condensing them into a liquid form, employing either the native moisture of the subject, or an addition of water, as a vehicle or matrix for retaining them.

The process which has been judged most analogous to that of nature, is the following. The subject fresh gathered at the season of its greatest vigour, with the morning dew on it, is laid lightly and unbruised in a shallow vessel, to which is adapted a low head with a recipient; under the vessel a live coal is placed, and occasionally renewed, so as to keep up an uniform heat, no greater than that which obtains in the atmosphere in summer, viz. about 85 degrees of Fahrenheit's thermometer. In this degree of heat there arises exceeding slowly an invisible vapour, which condenses in the head into dewy drops, and falls down into the receiver; and which has been supposed to be the very substance that the plant would have spontaneously emitted in the open air.

But on submitting many kinds of odoriferous vegetables to this process, the liquors obtained by it have been found to be very different from the natural effluvia of the respective subjects: they have had very little smell, and no remarkable taste. It appeared that a heat, equal to that of the atmosphere, is incapable of raising in close vessels those parts of vegetables which they emit in the open air. It may therefore be presumed that in this last case some other cause concurs to the effect: that it is not the sun's heat alone which raises and impregnates the air with the odorous principles of vegetables, but that the air itself, or the watery humidity with which it abounds, acting as a true solvent, extracts and imbibes them; so that the natural effluvia of a plant may be considered as an infusion of the plant made in air. The purgative virtue of the damask rose, and the astringency of the walnut-tree, which, as above observed, are in some degree communicated to the air, may be totally extracted by infusion both in watery and spirituous menstrua, but never rise in distillation with any degree of heat: and the volatile odours of aromatic herbs, which are diffused through the atmosphere in the lowest warmth, cannot be made to distil without a heat much greater than is ever found to obtain in a shaded air.

We apprehend, that the effluvia arising from growing vegetables are chiefly exhaled by the living energy of the plant: the odorous matter is a real secretion, which cannot be performed independent of active vessels; and it is as reasonable to allow the same powers for the exhalation of these effluvia, as for the transpiration of their watery parts.

The above process, therefore, and the theory on which it is built, appear to be faulty in two points: 1. In supposing that all these principles, which naturally exhale from vegetables, may be collected by distillation; whereas there are many which the air extracts in virtue of its solvent power; some are also incapable of being collected in a viable and elastic form; and some are artificially separable by solvents only: 2. In employing a degree of heat insufficient for separating even those parts which are truly exhalable by heat.

The foregoing method of distillation is commonly called *distillation by the cold still*; but those who have practised it have generally employed a considerable heat. A shallow leaden vessel is filled with the fresh herbs, flowers, &c. which are heaped above it; so that when the head is fitted on, this also may be filled a considerable way. A little fire is made under the vessel,

fel, sufficient to make the bottom much hotter than the hand can bear, care being only taken not to heat it so far as to endanger scorching any part of the subject. If the bottom of the vessel be not made so hot as to have this effect on the part contiguous to it, it is not to be feared that the heat communicated to the rest of the included matter will be so great as to do it any injury. By this management, the volatile parts of several odorous plants, as mint, are effectually forced over; and if the process has been skilfully managed, the distilled liquor proves richly impregnated with the native odour and flavour of the subject, without having received any kind of disagreeable impression from the heat used.

This process has been chiefly practised in private families; the slowness of the distillation, and the attendance and care necessary for preventing the scorching of some part of the plant, so as to communicate an ungrateful burnt flavour to the liquor, rendering it inconsistent with the dispatch requisite in the larger way of business.

Another method has therefore been had recourse to, viz. by the common still, called, in distinction from the foregoing, the *bol-still*. Here a quantity of water is added to the plant to prevent its burning; and the liquor is kept nearly of a boiling heat, or made to boil fully, so that the vapour rises plentifully into the head, and passing thence into a spiral pipe or worm placed in a vessel of cold water, is there condensed, and runs out in drops quickly succeeding each other, or in a continued stream. The additional water does not at all weaken the produce; for the most volatile parts of the subject rise first, and impregnate the liquor that first distils; as soon as the plant has given over its virtue sufficiently, which is known by examining from time to time the liquor that runs from the nose of the worm, the distillation is to be stopped.

This is the method of distillation commonly practised for the officinal waters. It is accompanied with one imperfection, affecting chiefly those waters whose principal value consists in the delicacy of their flavour; this being not a little injured by the boiling heat usually employed, and by the agitation of the odorous particles of the subject with the water. Sometimes also a part of the plant sticks to the sides of the still, and is so far scorched as to give an ungrateful taint to the liquor.

There is another method of managing this operation, which has been recommended for the distillation of the more volatile essential oils, and which is equally applicable to that of the waters. In this way the advantages of the foregoing methods are united, and their inconveniences obviated. A quantity of water being poured into the still, and the herbs or flowers placed in a basket over it, there can be no possibility of burning; the water may be made to boil, but so as not to rise up into the basket, which would defeat the intention of this contrivance. The hot vapour of the water passing lightly through all the interstices of the subject matter, imbibes and carries over the volatile parts unaltered in their native flavour. By this means the distilled waters of all those substances whose oils are of the most volatile kind, are obtained in the utmost perfection, and with sufficient dispatch; for which

last intention the still may be filled quite up to the head.

In the distillation of essential oils, the water, as was observed in the foregoing section, imbibes always a part of the oil. The diluted liquors here treated of are no other than water thus impregnated with the essential oil of the subject; whatever smell, taste, or virtue is here communicated to the water, or obtained in the form of a watery liquor, being found in a concentrated state in the oil. The essential oil, or some part of it, more attenuated and subtilized than the rest, is the direct principle on which the title of *Spiritus rectior*, or *preliding spirit* has been bestowed.

All those vegetables therefore which contain an essential oil, will give over some virtue to water by distillation: but the degree of the impregnation of the water which a plant is capable of saturating with its virtue, are by no means in proportion to the quantity of its oil. The oil saturates only the water that comes over at the same time with it: if there be more oil than is sufficient for this saturation, the surplus separates, and concretes in its proper form, not miscible with the water that arises afterwards. Some odoriferous flowers, whose oil is, in so small quantity, that scarcely any visible mark of it appears, unless fifty or an hundred pounds or more are distilled at once, give nevertheless as strong an impregnation to water as those plants which abound most with oil.

Many have been of opinion, that distilled waters may be more and more impregnated with the virtues of the subject, and their strength increased to any assigned degree, by *cohabitation*, that is, by redistilling them a number of times from fresh parcels of the plant. Experience, however, shews the contrary; a water skilfully drawn in the first distillation, proves on every repeated one not stronger but more disagreeable. Aqueous liquors are not capable of imbibing above a certain quantity of the volatile oil of vegetables; and this they may be made to take up by one as well as by any number of distillations: the oftener the process is repeated, the ungrateful impression which they generally receive from the fire, even at the first time, becomes greater and greater. Those plants, which do not yield a strong waters sufficiently strong, are not proper subjects for this process, since their virtue may be obtained much more advantageously by others.

General rules for the DISTILLATION of the OFFICINAL SIMPLE WATERS.

1. Where they are directed fresh, such only must be employed: but some are allowed to be used dry, as being easily procurable in this state at all times of the year, though rather more elegant waters might be obtained from them while green.

When fresh and juicy herbs are to be distilled, three times their weight of water will be fully sufficient; but dry ones require a much larger quantity. In general, there should be so much water, that after all intended to be distilled has come over, there may be liquor enough left to prevent the matter from burning to the still.

Plants differ so much, according to the soil and season of which they are the produce, and likewise according to their own age, that it is impossible to fix

the quantity of water to be drawn from a certain weight of them to any invariable standard. The distillation may always be continued as long as the liquor runs well flavoured off the subject, and no longer.

2. The distillation may be performed in an alembic with a refrigeratory, the junctures being luted.
3. If the herbs are of prime goodness, they must be taken in the weights prescribed: but when fresh ones are substituted for dry, or when the plants themselves are the produce of unfavourable seasons, and weaker than ordinary, the quantities are to be varied according to the discretion of the artist.

After the odorous water, alone intended for use, has come over, an acidulous liquor arises, which has sometimes extracted so much from the copper head of the still as to prove emetic. To this are owing the anthelmintic virtues attributed to certain distilled waters.

4. In a preceding edition of the Edinburgh pharmacopœia, some vegetables were ordered to be slightly fermented with the addition of yeast previously to the distillation.

The principle on which this management is founded, is certainly just; for the fermentation somewhat opens and unlocks their texture, so as to make them part with more in the subsequent distillation than could be drawn over from them without some assistance of this kind. Those plants, however, which require this treatment, are not proper subjects for simple waters to be drawn from, their virtues being obtainable to better advantage by other processes.

5. If any drops of oil swim on the surface of the water, they are to be carefully taken off.
6. That the waters may keep the better, about a 20th part their weight of proof-spirit may be added to each after they are distilled.

A great number of distilled waters were formerly kept in the shops, and are still retained in foreign pharmacopœias. The faculty of Paris direct, in the last edition of their *Codex Medicamentarius*, no less than 125 different waters, and 130 different ingredients in one single water. Nearly one half of these preparations have scarcely any virtue or flavour from the subject, and many of the others are insignificant.

The colleges of London and Edinburgh have rejected these ostentatious superfluities, and given an elegant and compendious set of waters, sufficient for answering such purposes as these kinds of preparations are applied to in practice. Distilled waters are employed chiefly as grateful diluents, as suitable vehicles for medicines of greater efficacy, or for rendering disagreeable ones more acceptable to the palate and stomach; few are depended on, without any intention of consequence, by themselves.

Distilled water. L.

321

Take of spring-water, 10 gallons. Draw off by distillation, first, four pints; which being thrown away, draw off four gallons. This water is to be kept in a glass or earthen bottle with a glass stopper.

Distilled water. E.

Let well or river water be distilled in very clean vessels till about two thirds are drawn off.

Native water is seldom or never found pure, and generally contains earthy, saline, metallic, or other matters. Distillation is therefore employed as a means of freeing it from these heterogeneous parts. For some pharmaceutical purposes distilled water is absolutely necessary: thus, if we employ hard undistilled water for dissolving sugar of lead, instead of a perfect solution, we produce a milky-like cloud, owing to a real decomposition of parts.

Distilled water is now employed by the London college for a great variety of purposes; and there can be no doubt, that in many chemical and pharmaceutical processes, the employment of a heterogeneous fluid, in place of the pure element, may produce an essential alteration of qualities, or frustrate the intention in view. While the London college have made more use of distilled water than any other, their directions for preparing it seem to be the best. For as some impregnations may be more volatile than pure water, the water may be freed from them by throwing away what comes first over; and by keeping it afterwards in a cloie vessel, absorption from the air is prevented.

Dill-water L.

Take of dill-seed, bruised, one pound; water, sufficient to prevent an empyreuma. Draw off one gallon.

322

Simple dill-seed water. E.

Take of dill-seeds, one pound; pour on as much water as when ten pounds have been drawn off by distillation there may remain as much as is sufficient to prevent an empyreuma. After proper maceration, let ten pounds be drawn off.

Although the dill-water holds a place, not only in the London and Edinburgh pharmacopœias, but also in most of the foreign ones; yet it is not much employed in practice. It obtains, indeed, a pretty strong impregnation from the seeds, and is sometimes employed as a carminative, particularly as the basis of mixtures and juleps; but it is less powerful and less agreeable than that of peppermint, cinnamon, and some others.

Cinnamon water. L. E.

Take of cinnamon, bruised one pound; water, sufficient to prevent an empyreuma. Macerate for 24 hours, and draw off one gallon.

323

From one pound of cinnamon the Edinburgh college direct 10 pounds of water to be drawn off; and if the cinnamon employed be of good quality, it may yield that quantity with a strong impregnation: but what comes over first is unquestionably the strongest.

This is a very grateful and useful water, possessing in an eminent degree the fragrance and aromatic cordial virtues of the spice. Where real cinnamon water is wanted, care should be had in the choice of the cinnamon. To avoid the too common imposition of callia being substituted in its room. The two drugs may be easily distinguished from each other by a variety of marks, which it is needless to introduce in this place. See CASSIA and CINNAMON. But the essential oils of the two approach so near, that after distillation it is perhaps impossible to distinguish the waters; and it is still more doubtful how far the one is in any degree preferable to the other.

Preparations and Compositions.

The oil of cinnamon is very ponderous, and arises more difficultly than that of any other of the vegetable matters from which simple waters are ordered to be drawn. This observation directs us, in the distillation of this water, to use a quick fire and a low vessel. For the same reason, the water does not keep so well as might be wished; the ponderous oil parting from it in time, and falling to the bottom, when the liquor loses its milky hue, its fragrant smell, and aromatic taste. Some recommend a small proportion of sugar to be added, in order to keep the oil united with the water.

Cassia-water. E.

- 324 From a pound and a half of the cassia bark, ten pounds of water are directed to be drawn off in the same manner as the dist-water.

This distilled water, as we have already observed, when properly prepared, approaches so near to that of cinnamon, that it is almost, if not altogether, impossible to distinguish the difference between the two. And though the London college has given it no place in their pharmacopœa, yet we may venture to assert, that it is no stranger in the shops of the apothecaries. Nay, so great is the difference of price, and the sensible qualities so nearly alike, that what is sold under the name of cinnamon-water is almost entirely prepared from cassia alone; and not even prepared from the cassia bark, as directed by the Edinburgh college, but from the cassia buds, which may be had at a still cheaper rate, and which yield precisely the same essential oil, although in less quantity. When cassia-water is prepared precisely according to the directions of the Edinburgh college, from containing a larger proportion of the subject, it has in general a stronger impregnation than their genuine cinnamon-water, and is probably in no degree inferior in its virtues.

Fennel-water. L.

- 325 Take of sweet fennel seeds, bruised, one pound; water, sufficient to prevent an empyreuma. Draw off one gallon.

The water of fennel seeds is not unpleasent. A water has also been distilled from the leaves. When these are enflorated, they should be taken before the plant has run into flower; for after this time they are much weaker and less agreeable. Some have observed, that the upper leaves and tops, before the flowers appear, yield a more elegant water, and a remarkably finer essential oil than the lower ones; and that the oil obtained from the one swims on the water, while that of the other sinks. No part of the herb, however, is equal in flavour to the seeds.

Peppermint-water.

- 326 Take of herb of peppermint, dried, one pound and an half; water, sufficient to prevent an empyreuma. Draw off one gallon. L.

From three pounds of the leaves of peppermint, ten pounds of water are to be drawn off. E.

This is a very elegant and useful water. It has a warm pungent taste, exactly resembling that of the peppermint itself. A spoonful or two taken at a time warm the stomach, and give great relief in cold flatulent colics. Some have substituted a plain infusion of

the dried leaves of the plant, which is not greatly different in virtue from the distilled water.

In the distillation of this water, a considerable quantity of essential oil generally comes over in its pure state. And it is not uncommon to employ this for impregnating other water, with which it may be readily mixed by the aid of a little sugar.

Spearmint-water. L.

- Take of spearmint, dried, one pound and an half; water sufficient to prevent an empyreuma. Draw off one gallon. 327

The Edinburgh college directs this water to be made in the same proportion as the preceding. But probably three pounds of the fresh herb will not give a stronger impregnation than a pound and a half of the dried: so that the water of the London college may be considered to be as strongly impregnated as that of the Edinburgh college.

This water smells and tastes very strongly of the mint; and proves in many cases an useful stomachic. Boerhaave commends it (colobated) as a pleasant and incomparable remedy for strengthening a weak stomach, and curing vomiting proceeding from cold viscid phlegm, and also in henterics.

All-spice-water. L. E.

- Take of all-spice, bruised, half a pound; water, sufficient to prevent an empyreuma. Macerate for 24 hours, and draw off one gallon. 328

From half a pound of the pimento the Edinburgh college directs ten pounds of water to be drawn off; so that the impregnation is there somewhat weaker than the above.

This distilled water is a very elegant one, and has of late come pretty much into use; the hospitals employ it as a succedaneum to the more costly spice-waters. It is, however, inferior in gratefulness to the spirituous water of the same spice hereafter directed.

Pennyroyal-water. L. E.

- Take of dried herb pennyroyal, one pound and an half; water, sufficient to prevent an empyreuma. Draw off one gallon. 329

The pennyroyal-water is directed to be prepared by the Edinburgh college in the same proportions as the mint and peppermint. Whether prepared from the recent or dried plant it possesses in a considerable degree the smell, taste, and, virtues of the pennyroyal. It is not unfrequently employed in hysterical cases, and sometimes with a good effect.

Rose-water. L. E.

- Take of fresh petals of the damask rose, the white heels being cut off, six pounds; water sufficient to prevent an empyreuma. Draw off one gallon. 330

From the same quantity the Edinburgh college directs ten pounds to be drawn off.

This water is principally valued on account of its fine flavour, which approaches to that generally admired in the rose itself. The purgative virtue of the roses remains entire in the liquor left in the still, which has therefore been generally employed for making the fountain honey and syrup, instead of a decoction or infusion of fresh roses prepared on purpose; and this

piece

piece of frugality the college have now admitted. A distilled water of red roses has been sometimes called for in the shops, and supplied by that of damask roses diluted with common water. This is a very venial substitution; for the water drawn from the red rose has no quality which that of the damask does not possess in a far superior degree; neither the purgative virtue of the one nor the astringency of the other arising in distillation.

Lemon-peel-water. E.

- 331 From two pounds of recent lemon-peel ten pounds of water are to be drawn off by distillation.

Orange-peel-water. E.

- 332 From two pounds of orange-peel ten pounds of water are directed to be drawn off.

Neither of these distilled waters are now to be met with in the London pharmacopœia; and it is probable that no great loss arises from the want of them, for both the one and the other contain only a very weak impregnation. They are chiefly employed as diluents in fevers and other disorders where the stomach and palate are very apt to be disgusted. And perhaps the only circumstance for which they are valuable is the lightness of the impregnation; for in such affections, any flavour, however agreeable at other times, often becomes highly disgusting to patients.

The distilled waters above noticed are the whole that have now a place in the pharmacopœias of the London and Edinburgh colleges; and perhaps this selection is sufficiently large for answering every useful purpose. But besides these, a considerable number of others are still even retained in the modern foreign pharmacopœias; some of which at least it may not be improper to mention.

Alexiterial water. Brun.

- 333 Take of elder flowers, moderately dried, three pounds; angelica leaves, fresh gathered, two pounds; spring water, forty pounds. Draw off, by distillation, thirty pounds.

This water is sufficiently elegant with regard to taste and smell; though few expect from it such virtues, as its title seems to imply. It is used occasionally for vehicles of alexipharmac medicines, or in juleps to be drank after them, as coinciding in the intention; but in general is not supposed to be itself of any considerable efficacy.

Camphor-water. Brun.

- 334 Take of camphor, an ounce and an half. Let it be dissolved in half an ounce of the spirit of rosemary, then pour on it two pounds of spring-water, and draw off by distillation a pound and an half.

This distilled water, which has no place in our pharmacopœias, is introduced into some of the foreign ones. And since camphor may be considered as a concrete essential oil, it naturally occurs as a form under which that medicine may be introduced with advantage in a diluted state.

Castor-water. Brun.

- 335 Take of Russia castor, one ounce; water, as much as will prevent burning. Draw off two pints.

Castor yields almost all its flavour in distillation to water, but treated in the same manner with spirit of wine gives over nothing. The spirit of castor formerly kept in the shops had none of the smell or virtues of the drug; while the water here directed proves, when fresh drawn, very strong of it.

It is remarkable, that the virtues of this animal-substance reside in a volatile oil, analogous to the essential oils of vegetables. Some are reported to have obtained, in distilling large quantities of this drug, a small portion of oil, which smelt extremely strong of the castor, and diffused its ungrateful scent to a great distance.

This water is used in hysteric cases, and some nervous complaints, though it has not been found to answer what many people expect from it. It loses greatly of its flavour in keeping.

And it is probably from this circumstance that it has no place either in our pharmacopœias or in the modern foreign ones; but at the same time, as possessing in a high degree the sensible qualities of the castor, it may be considered as justly deserving future attention.

Chervil-water. Gen.

Take of fresh leaves of chervil, one pound; spring-water as much as is sufficient for allowing eight pounds to be drawn off by distillation, at the same time avoiding empyreuma.

Although the chervil be but little employed in Britain, yet among some of the foreigners it is held in high esteem; and the distilled water is perhaps one of the most elegant forms under which its active parts can be introduced. But there is reason to believe that those diuretic powers, for which it has been chiefly celebrated, will be most certainly obtained from exhibiting it in substance, or under the form of the expressed juice of the recent plant.

Black-cherry-water. Suec.

Take of ripe black cherries bruised with the kernels, 20 pounds; pure water, as much as is sufficient for avoiding empyreuma. Draw off 20 pounds by distillation.

This water, although now banished from our pharmacopœias, has long maintained a place in the foreign ones, and even in Britain it is not unfrequently to be met with in the shops. It has often been employed by physicians as a vehicle, in preference to the other distilled waters; and among nurses who have the care of young children has been the first remedy against the convulsive disorders to which infants are so often subject.

This water has nevertheless of late been brought into disrepute, and has been esteemed poisonous. They observe, that it receives its flavour principally from the cherry stones; and that these kernels like many others, bear a resemblance in taste to the leaves of the lauro-cerasus, which have been discovered to yield, by infusion or distillation, the most sudden poison known. Some physicians in England have lately found, by trial purposely made, that a distilled water very strongly impregnated with the flavour of the cherry kernels (no more than two pints being distilled from fourteen pounds of the cherry stones) proved in like manner poisonous.

Prepara-
tions and
Composi-
tions.

poisonous to brutes. The London college repeated the same experiment, and found the effects agreeable to those gentlemen's report.

It by no means follows from these trials, nor after such long experience can it be imagined, that black-cherry water, when no stronger than the shops have been accustomed to prepare it, is unsafe. These kernels plainly resemble opium, and some other things, which poison only when taken in too great a quantity. The water from the very laurel leaves is harmless when duly diluted; and even spirit of wine proves a poison of its kind not greatly different, if drunk to a certain degree of excess. Nor can it be concluded, from the trials with the strong black-cherry water on dogs, &c. that even this will have the same effects in the human body; the kernels of many sorts of fruits being in substance poisonous to brutes, though innocent to man.

It is possible, however, that this water in any degree of strength may not be altogether safe to the tender age of infants, where the principles of life are but just beginning as it were to move. It is possible that it may there have had pernicious effects without being suspected; the symptoms it will produce, if it should prove hurtful, being such as children are often thrown into from the disease which it is imagined to relieve. On these considerations, both the London and Edinburgh colleges have chosen to lay it aside; more especially as it has been too often counterfeited with a water distilled from bitter almonds, which are known to communicate a poisonous quality. It is, however, one of those active articles which may perhaps be considered as deserving farther attention.

Camomil-flower water. Dan.

338 Take of camomile flowers, dried in the shade, eight pounds; water, 72 pounds. Draw off by gentle distillation 48 pounds.

Camomile flowers were formerly ordered to be fermented previously to the distillation, a treatment which they do not need; for they give over, without any fermentation, as much as that process is capable of enabling them to do. In either case the small and peculiar flavour of the flowers arise without any of the bitterness, this remaining behind in the decoction; which, if duly deperated and inspissated, yields an extract similar to that prepared from the flowers in the common manner. The distilled water has been used in flatulent colics and the like, but is at present held in no great esteem.

Strawberry water. Suc.

339 From 20 pounds of strawberries 20 pounds of distilled water are drawn off, according to the same directions given for the preparation of the black-cherry water.

Water thus impregnated with the essential oil of the strawberries some people will think of a very agreeable flavour, but any considerable medical power is not to be expected from it.

Hyssop-water. Suc.

340 From four pounds of the fresh leaves of hyssop six pounds of water are drawn off.

Hyssop-water has been held by some in considerable esteem as an uterine and pectoral medicine. It was

directed in a former edition of the Edinburgh pharmacopœia for making up the black-pectoral troches, but is now exchanged for common water. Few at present expect any singular virtues from it, nor is it often to be met with in our shops, being now expunged from our pharmacopœias. It holds a place, however, in most of the foreign ones, and among ourselves there are still some practitioners who frequently employ it. But there can be no doubt that those medical properties which the hyssop contains may be more readily and effectually extracted by simple infusion.

White lily water. Brun.

Lily-of-the-valley-water. Brun.

To any quantity of these flowers four times their weight of water is to be added, and water drawn off by distillation in the proportion of two pounds to each pound of the flowers.

These waters must obtain some impregnation of that elegant essential oil on which the odour of flowers in their growing state depends. But they do not possess any remarkable medical properties.

Balm-water. Brun.

The green leaves of the balm are to be macerated with double their weight of water; and from each pound of the plant a pound and an half of water is to be drawn off.

This water contains a considerable impregnation from the balm, which yields its essential oil pretty freely on distillation. Though now banished from our pharmacopœias, it has still a place in most of the foreign ones. In the old editions of the Edinburgh pharmacopœia, this water was ordered to be cohobated or redistilled from fresh quantities of the herb. This management seems to have been taken from Boerhaave, who has a very high opinion of the water thus prepared: he says, he has experienced in himself extraordinary effects from it taken on an empty stomach: that it has scarce its equal in hypochondriacal and hysterical cases, the chlorosis, and palpitation of the heart, as often as these diseases proceed from a disorder of the spirits rather than from any collection of morbid matter.

But whatever virtues are lodged in balm, they may be much more perfectly and advantageously extracted by cold infusion in aqueous or spirituous menstrua: in this last process, the liquor suffers no injury from being returned on fresh parcels of the herb: a few repetitions will load it with the virtues of the substance, and render it very rich. The impregnation here is almost unlimited; but in distilled waters it is far otherwise.

Rue water. Reif.

From each pound of rue, with a sufficient quantity of spring-water to prevent empyreuma, two pounds of distilled water are to be drawn.

Rue gives over in this process the whole of its smell, and great part of its pungency. The distilled water stands recommended in epileptic cases, the hysteric passion, for promoting perspiration, and other natural secretions. But though it is a good deal employed abroad, it is with us falling into disrepute.

Preparations and Compositions.

Savin-water.

This is distilled from the fresh leaves of *savin*, after the same manner as the other already mentioned.

This water is by some held in considerable esteem for the same purposes as the distilled oil of *savin*. Boerhaave relates, that he has found it (when prepared by cohobation) to give an almost incredible motion to the whole nervous system: and that, when properly used, it proves eminently serviceable for promoting the menses and the hemorrhoidal flux.

It has now, however, fallen so much into disrepute as to have no place either in our pharmacopœias or in the best modern foreign ones: But at the same time, when we reflect how readily *savin* yields a large proportion of active essential oil on distillation, it may perhaps be considered as better entitled to attention than some other distilled waters which are still retained.

Elder-flower-water. Brun.

345 This is distilled from fresh elder flowers, after the same manner as the white-lily water.

This water smells considerably of the flowers; but is rarely used among us.

Sage-water. Brun.

346 This is directed to be prepared from the green leaves of the *sage* in the same manner as the *balm-water*.

Sage leaves contain a considerable proportion of essential oil, which they yield pretty freely on distillation. But their whole medical properties may with still greater ease and advantage be extracted by single infusion.

To the simple distilled waters the London college have annexed the following remarks.

We have ordered the waters to be distilled from the dried herbs, because fresh are not ready at all times of the year. Whenever the fresh are used, the weights are to be increased. But whether the fresh or dried herbs be employed, the operator may vary the weight according to the season in which they have been produced and collected.

Herbs and feeds kept beyond the space of a year are less proper for the distillation of waters.

To every gallon of these waters add five ounces, by measure, of proof-spirit.

CHAP. XVIII. *Distilled Spirits.*

347 The flavours and virtues of distilled waters are owing, as was observed in the preceding chapter, to their being impregnated with a portion of the essential oil of the subject from which they are drawn. Spirit of wine, considered as a vehicle for these oils, has this advantage above water, that it is their proper menstruum, and keeps all the oil that rises with it perfectly dissolved into an uniform limpid liquor.

Nevertheless, many substances, which, on being distilled with water, impart to it their virtues in great perfection; if treated in the same manner with spirit of wine, scarcely give it any smell or taste. This difference proceeds from hence, that spirit is not susceptible of so great a degree of heat as water. Liquids

in general when made to boil, have received as great a heat as they are capable of sustaining; now, if the extent of heat between freezing and boiling water, as measured by thermometers, be taken for a standard, spirit of wine will be found to boil with less than four-fifths of that heat, or above one-fifth less than the heat of boiling water. It is obvious, therefore that substances may be volatile enough to rise with the heat of boiling water, but not with that of boiling spirit.

Thus, if cinnamon, for instance, be committed to be distilled with a mixture of spirit of wine and water, or with a pure proof-spirit, which is no other than a mixture of about equal parts of the two; the spirit will rise first, clear, colourless, and transparent, and almost without any taste of the spice; but as soon as the more ponderous watery fluid begins to rise, the oil comes over freely with it, so as to render the liquor highly odorous, sapid, and of a milky hue.

The proof-spirits usually met with in the shops are accompanied with a degree of ill flavour; which, though concealed by means of certain additions, plainly discovers itself in distillation. This nauseous relish does not begin to rise till after the purer spirituous part has come over; which is the very time that the virtues of the ingredients begin also most plentifully to distil: and hence the liquor receives an ungrateful taint. To this cause principally is owing the general complaint, that the cordials of the apothecary are less agreeable than those of the same kind prepared by the distiller: the latter being extremely curious in rectifying or purifying the spirits (when designed for what he calls fine goods) from all ill flavour.

Ardent Spirit. L.

Take of rectified spirit of wine, one gallon; kali, made hot, one pound and an half; pure kali, one ounce. Mix the spirit of wine with the pure kali, and afterwards add one pound of the hot kali, and shake them, and digest for twenty-four hours. Pour off the spirit, to which add the rest of the kali, and distil in a water bath. It is to be kept in a vessel well stopped. The specific gravity of the alcohol is to that of distilled water as 815 to 1000.

We have already offered some observations on spirit of wine both in the state of what is called *rectified* and *proof-spirit*. But in the present formula we have ardent spirit still more freed from an admixture of water than even the former of these. And in this state it is unquestionably best fitted for answering some purposes. It may therefore be justly considered as an omission in the present edition of the Edinburgh pharmacopœia, that they have no analogous form. In former editions of this work, alcohol was directed to be prepared from French brandy. But this is rather too dear an article in this country for distillation; nor is the spirit obtained from it anywise preferable to one procurable from cheaper liquors. The coarser inflammable spirits may be rendered perfectly pure, and fit for the nicest purposes, by the following method.

If the spirit be exceedingly foul, mix it with about an equal quantity of water, and distil with a slow fire; discontinuing the operation as soon as the liquor begins to run milky, and discovers by its nauseous taste that the impure and phlegmatic part is rising. By this

Preparations and Compositions.

Preparations and Compositions.

treatment, the spirit leaves a considerable portion of its foul oily matter behind it in the water, which now appears milky and turbid, and proves highly disagreeable to the taste. If the spirit be not very foul at first, this ablution is not necessary; if extremely so, it will be needful to repeat it once, twice, or oftener.

As vinous spirits arise with a less degree of fire than watery liquors, we are hence directed to employ, in the distillation of them, a heat less than that in which water boils; and if due regard be had to this circumstance, very weak spirits may, by one or two wary distillations, be tolerably well freed from their aqueous phlegm; especially if the distilling vessels are of such a height, that the spirit, by the heat of a water-bath, may but just pass over them: in this case, the phlegmatic vapours which rise for a little way along with the spirit, will condense and fall back again before they can come to the head. Very pompous instruments have been contrived for this purpose, and carried in a spiral or serpentine form to an extraordinary height. The spirit ascending through these, was to leave all the watery parts it contained in its passage, and come over perfectly pure and free from phlegm. But these instruments are built upon erroneous principles, their extravagant height defeating the end it was designed to answer; if the liquor be made to boil, a considerable quantity of mere phlegm will come over along with the spirit; and if the heat be not raised to this pitch, neither phlegm nor spirit will distil. The most convenient instrument is the common still; between the body of which and its head an adppter or copper tube may be fixed.

The spirit being washed, as above directed, from its foul oil, and freed from the greatest part of the phlegm by gentle distillation in a water-bath, add to every gallon of it a pound or two of pure dry fixed alkaline salt. Upon digesting these together for a little time, the alkali, from its known property of attracting water and oils, will imbibe the remaining phlegm, and such part of the disagreeable unctuous matter as may still be left in the spirit, and will sink with them to the bottom of the vessel. If the spirit be now again gently drawn over, it will rise entirely free from its phlegm and nauseous flavour; but some particles of the alkaline salt are apt to be carried up with it, and give what the workmen call an *urinous relish*: this may be prevented by adding, previous to the last distillation, a small proportion of calcined vitriol, alum or bitter earthy salt; the acids of these salts will unite with and neutralize the alkali, and effectually prevent it from rising: while no more of the acid of the salt is extricated than what the alkali absorbs.

The spirit obtained by this means is extremely pure, limpid, perfectly flavourless, and fit for the finest purposes. It may be reduced to the strength commonly understood by proof, by mixing twenty ounces of it with seventeen ounces of water. The distilled cordials made with these spirits prove much more elegant and agreeable, than when the common rectified or proof-spirits of the shops are used.

If the rectified spirit be distilled afresh from dry alkaline salt with a quick fire, it brings over a considerable quantity of the salt; and in this state it is supposed to be a more powerful menstruum for certain

substances than the pure spirit. This alkulized spirit is called *tartarized spirit of wine*.

The process here described, which was long since recommended by Dr Lewis, will sufficiently explain the intention of the London college, in the directions they have now given for the preparation of alcohol. And there can be no doubt, that by their process a very pure alcohol may be obtained. Of this we have a sufficient test in the specific gravity of the fluid which comes over, which is to that of distilled water only as 815 to 1000, while the specific gravity of proper rectified spirit is as 835 to 1000.

Spirit of vitriolic aether. L.

Take of rectified spirit of wine, vitriolic acid, each one pound. Pour by a little at a time the acid on the spirit, and mix them by shaking; then from a retort through a tubulated receiver, to which an ather recipient is fitted, distil the spirit of vitriolic aether till sulphureous vapours begin to rise.

Vinous vitriolic acid, commonly called dulcified spirit of vitriol. E.

Take of vitriolic ethereal liquor, one part; rectified spirit of wine, two parts. Mix them.

The last of these processes is a very ready and convenient method of preparing the dulcified spirit of vitriol, which only differs from ather by the acid being more predominant, and less intimately combined.

In the first process, a good deal of caution is requisite in mixing the two liquors. Some direct the spirit of wine to be put first into the retort, and the oil of vitriol to be poured upon it all at once; a method of procedure by no means advisable, as a violent heat and ebullition always ensue, which not only dissipate a part of the mixture, but hazard also the breaking of the vessel, to the great danger of the operator. Others put the oil of vitriol into the retort first: then by means of a funnel, with a long pipe that may reach down just to the surface of the acid, pour in the spirit of wine: if this be done with sufficient caution, the vinous spirit spreads itself on the surface of the oil of vitriol, and the two liquors appear distinct. On standing for a week or two, the vinous spirit is gradually imbibed, without any commotion, and the vessel may then be safely shaken to complete the mixture; but if the spirit be poured in too hastily at first, or if the vessel be moved before the two liquors have in some degree incorporated, the same effect ensues as in the foregoing case. The only secure way is, to add the oil of vitriol to the spirit of wine by a little quantity at a time, waiting till the first addition be incorporated before another quantity is put in; by this management the heat that ensues is inconsiderable, and the mixture is effected without any inconvenience.

The distillation should be performed with an equable and very gentle heat, and not continued so long as till a black froth begins to appear: for before this time a liquor will arise of a very different nature from the spirits here intended. The several products are most commodiously kept apart by using a tubulated receiver, so placed that its pipe may convey the matter which shall come over into a vial set underneath. The juncture of the retort and recipient is to be luted with a

Preparations and Compositions.

paste made of lintseed meal, and further secured by a piece of wet bladder; the lower juncture may be closed only with some soft wax, that the vial may be occasionally removed with ease.

The true dulcified spirit arises in thin subtile vapours which condense on the sides of the recipient in straight striæ. It is colourless as water, very volatile, inflammable, of an extremely fragrant smell, in taste somewhat aromatic.

After the fire has been kept up for some time, white fumes arise: which either form irregular striæ, or are collected into large round drops like oil: On the first appearance of these, the vial, or the receiver, if a common one is used, must be taken away. If another be substituted and the distillation continued, an acid liquor comes over, of an exceeding pungent smell like the fumes of burning brimstone. At length a black froth begins lately to arise, and prevents carrying the process further.

On the surface of the sulphurous spirit is found swimming a small quantity of oil, of a light yellow colour, a strong, penetrating, and very agreeable smell. This oil seems to be nearly of the same nature with the essential oils of vegetables. It readily and totally dissolves in rectified spirit of wine, and communicates to a large quantity of that menstruum the taste and smell of the aromatic or dulcified spirit.

The matter remaining after the distillation is of a dark blackish colour, and still highly acid. Treated with fresh spirit of wine, in the same manner as before, it yields the same production: till at length all the acid that remains unvolatilised being saturated with the inflammable oily matter of the spirit, the compound proves a bituminous sulphureous mass; which, exposed to the fire in open vessels, readily burns, leaving a considerable quantity of fixed ashes; but in close ones it explodes with violence; with fixed alkaline salts it forms a compound nearly similar to one composed of alkalis and sulphur.

The new names adopted by the London and Edinburgh colleges for this fluid, are expressive of its composition; the one employed the term of *spiritus ætheris vitriolici*, the other of *acidum vitriolicum vinosum*; the old term of *spiritus vitrioli dulcis* is less properly fitted to distinguish it from other fluids, and to convey a just idea of its nature.

Dulcified spirit of vitriol has been for some time greatly esteemed, both as a menstruum and a medicine. It dissolves some resinous and bituminous substances more readily than spirit of wine alone, and extracts elegant tinctures from sundry vegetables. As a medicine, it promotes perspiration and the urinary secretion, expels flatulencies, and in many cases abates spasmodic stricures, eases pains, and procures sleep. The dose is from ten to eighty or ninety drops in any convenient vehicle. It is not essentially different from the celebrated anodyne liquor of Hoffman; to which it is, by the author himself, not unfrequently directed as a succedaneum.

Of this fluid however, or at least of an article still more nearly resembling it, we shall afterwards have occasion to speak, when we treat of the vinous spirit of vitriolic æther.

Vitriolic æther. L.

Take of the spirit of vitriolic ether, two pounds; wa-

ter of pure kali one ounce. Shake them together, and distil, with a gentle heat, fourteen ounces by measure.

Preparations and Compositions.

Vitriolic ethereal liquor. E.

Take of rectified spirit of wine, vitriolic acid, each thirty-two ounces. Pour the spirit into a glass retort fit for sustaining a sudden heat, and add to it the acid in an uniform stream. Mix them by degrees frequently shaking them moderately; this done, instantly distil from sand previously heated for that purpose, into a receiver kept cool with water or snow. But the heat is to be managed, that the liquor shall boil at first, and continue to boil till 16 ounces are drawn off; then let the retort be raised out of the sand.

To the distilled liquor add two drams of the common Lixiv. caustic; then distil again in a very high retort with a very gentle heat, into a cool receiver, until ten ounces have been drawn off.

If sixteen ounces of rectified spirit of wine be poured upon the acid remaining in the retort after the first distillation, an ethereal liquor may be obtained by repeating the distillation. This may be done pretty often.

The preparation of this singular fluid, now received into public pharmacopœias, was formerly confined to a few hands; for though several processes have been published for obtaining it, the success of most of them is precarious and some of them are accompanied also with danger to the operator. The principal difficulty consists in the first part of the distillation.

It has been usual to direct the heat to be kept up till a black froth begins to appear: but if it is managed in the manner here directed, the quantity of æther which the liquor can afford will be formed and drawn off before this sulphureous froth appears. The use of the caustic alkali is to engage any uncombined vitriolic acid which may be present in the first distilled liquor. If a mild alkali were employed for this purpose, the separation of its air by the acid might endanger the bursting of the vessel. The last is indeed an inconvenience which attends the whole of this process. It might in a great measure be obviated by employing a range of receivers such as the adopter described in the first part of this work.

The æther, or ethereal spirit, is the lightest, most volatile and inflammable of all known liquids. It is lighter than the most highly rectified spirit of wine, in the proportion of about 7 to 8; a drop, let fall on the hand, evaporates almost in an instant, scarcely rendering the part moist. It does not mix, or only in a small quantity, with water, spirit of wine, alkaline lixivium, volatile alkaline spirits, or acids; but is a powerful dissolvent for oils, balsams, resins, and other analogous substances; it is the only known substance capable of dissolving the elastic gum: it has a fragrant odour, which in consequence of the volatility of the fluid, is diffused through a large space. It has often been found to give ease in violent headaches, by being applied externally to the part; and to relieve the toothach, by being laid on the afflicted jaw. It has been given also internally, with benefit, in hooping coughs, hysterical cases, in asthma, and indeed in almost every spasmodic affection, from a few drops to the

Prepara-
tions and
Composi-
tions.

the quantity of half an ounce, in a glass of wine or water; which should be swallowed as quickly as possible, as the æther so speedily exhales.

Spirit of nitrous æther. L.

351 Take of rectified spirit of wine, two pints; nitrous acid, half a pound. Mix them, by pouring in the acid on the spirit, and distil with a gentle heat one pound ten ounces.

Vinous acid of nitre, commonly called dulcified spirit of nitre. E.

Take of rectified spirit of wine, three pounds; nitrous acid one pound. Pour the spirit into a capacious phial, placed in a vessel full of cold water, and add the acid by degrees, constantly agitating them. Let the phial be slightly covered, and laid by for seven days in a cool place; then distil the liquor with the heat of boiling water, into a receiver kept cool with water or snow, till no more spirit comes over.

By allowing the acid and rectified spirit to stand for some time, the union of the two is not only more complete, but the danger also of the vessels giving way to the ebullition and heat consequent on their being mixed, is in a great measure prevented. By fixing the degree of heat to the boiling point, the superabundant acid matter is left in the retort, being too ponderous to be raised by that degree of heat.

Here the operator must take care not to invert the order of mixing the two liquors, by pouring the vinous spirit into the acid; for if he should, a violent effervescence and heat would ensue, and the matter be dispersed in highly noxious red fumes. The most convenient and safe method of performing the mixture seems to be to put the inflammable spirit into a large glass bottle with a narrow mouth, placed under a chimney, and to pour into it the acid, by means of a glass funnel, in very small quantities at a time; shaking the vessel as soon as the effervescence ensuing upon each addition ceases, before a fresh quantity is put in: by this means the glass will be heated equally, and be prevented from breaking. During the action of the two spirits upon each other, the vessel should be slightly covered: if close stopped, it will burst; and if left entirely open, some of the more valuable parts will exhale. Lemery directs the mixture to be made in an open vessel; by which unscientific procedure, he usually lost, as he himself observes, half his liquor; and we may presume, that the remainder was not the medicine here intended.

Several methods have been contrived for obviating the inconveniences arising from the elastic fluid and violent explosions produced on the mixture of the nitrous acid and rectified spirit of wine: for preparing the nitrous æther they are absolutely necessary, and might perhaps be conveniently used for making the dulcified spirit. The method we judge to be the best, is that employed by Dr Black. On two ounces of the strong acid put into a phial, the distor pours, slowly and gradually, about an equal quantity of water; which, by being made to trickle down the sides of the phial, floats on the surface of the acid without mixing with it: he then adds, in the same cautious

manner, three ounces of highly rectified spirit of wine, which in its turn floats on the surface of the water. By this means the three fluids are kept separate on account of their different specific gravities, and a stratum of water is interposed between the acid and spirit. The phial is now set in a cool place: the acid gradually ascends and the spirit descends through the water, this last acting as a boundary to restrain their violent action on each other. By this method a quantity of nitrous æther is formed, without the danger of producing elastic vapours or explosion.

For the preparation of the dulcified spirit, the liquors, when mixed together, should be suffered to rest for some time as above directed, that the fumes may entirely subside, and the union be in some measure completed. The distillation should be performed with a very slow and well regulated fire; otherwise the vapour will expand with so much force as to burst the vessels. Wilson seems to have experienced the justness of this observation, and hence directs the juncture of the retort and receiver not to be luted, or but slightly: if a tubulated recipient, with a sufficiently long pipe, be used, and the distillation performed with the heat of a water-bath, the vessels may be luted without any danger: this method has likewise another advantage, as it ascertains the time when the operation is finished: examining the distilled spirit every now and then with alkaline salt, as directed above, is sufficiently troublesome; while in a water-bath we may safely draw over all that will rise; for this heat will elevate no more of the acid than what is dulcified by the vinous spirit.

Dulcified spirit of nitre has been long held, and not undeservedly, in great esteem. It quenches thirst, promotes the natural secretions, expels flatulencies, and moderately strengthens the stomach: it may be given from 20 drops, to a dram, in any convenient vehicle. Mixed with a small quantity of spirit of hartshorn, the volatile aromatic spirit, or any other alkaline spirit, it proves a mild, yet efficacious, diaphoretic, and often remarkably diuretic; especially in some febrile cases, where such a salutary evacuation is wanted. A small proportion of this spirit added to malt spirits, gives them a flavour approaching to that of French brandy.

Spirit of ammonia. L.

Take of proof spirit, three pints; sal ammoniac, four ounces; potash, six ounces. Mix and distil with a slow fire one pint and an half.

Vinous Spirit of sal ammoniac. E.

Take of quicklime, 16 ounces: sal ammoniac, eight ounces; rectified spirit of wine, 32 ounces. Having slightly bruised and mixed the quicklime and ammoniacal salt, put them into a glass retort; then add the spirit, and distil in the manner directed for the volatile caustic alkali, till all the spirit has passed over.

This spirit has lately come much into esteem, both as a medicine and a menstruum. It is a solution of volatile salt in rectified spirit of wine; for though proof spirit be used, its phlegmatic part does not rise in the distillation, and serves only to facilitate the action of the pure spirit upon the ammoniacal salt.

Rectified

Prepara-
tions and
Composi-
tions.

Preparations and Compositions.

Rectified spirit of wine does not dissolve volatile alkaline salts by simple mixture: on the contrary, it precipitates them, as has been already observed, when they are previously dissolved in water: but by the present process, a considerable proportion of the volatile alkali is combined with the spirit. It might perhaps, for some purposes, be more advisable to use with this intention the volatile spirit made with quicklime; for this may be mixed at once with rectified spirit of wine, in any proportion, without the least danger of any separation of the volatile alkali.

The name here employed by the London college, particularly when put in contradistinction to the water of ammonia, conveys a clear idea of the article, and is, we think preferable to that employed by the Edinburgh college.

As a menstruum, the spirit of ammonia is employed to dissolve essential oils, thus forming the volatile aromatic spirit, or *compound spirit of ammonia*, as it is now called by the London college, which again is employed in making the tinctures of guaiac, valerian, &c.

The chief medical virtues which the spirit of ammonia possesses, when exhibited by itself, are those of the volatile alkali.

Fetid spirit of ammonia.

353 Take of proof-spirit, six pints; sal ammoniac, one pound; asafetida, four ounces; pot-ash, one pound and a half. Mix them and draw off by distillation five pints, with a slow fire. *L.*

Take of vinous spirit of sal ammoniac, eight ounces; asafetida, half an ounce. Digest in a close vessel 12 hours; then distil off with the heat of boiling water eight ounces. *E.*

This spirit, the last formula of which is in our opinion the best, as being most easily prepared without any risk of being injured in the preparation, is designed as an antihysteria, and is undoubtedly a very elegant one. Volatile spirits impregnated for these purposes with different fetids, have been usually kept in the shops; the ingredient here made choice of, is the best calculated of any for general use, and equivalent in virtue to them all. The spirit is pale when newly distilled, but acquires a considerable tinge in keeping.

Compound spirit of aniseed. L.

354 Take aniseed, angelica-feed, of each bruised, half a pound; proof spirit, one gallon; water, sufficient to prevent an empyreuma. Draw off one gallon by distillation.

This compound spirit is now directed to be prepared by the London college in the same manner as in their former edition. It has no place in the Edinburgh pharmacopœia: but it may justly be considered as a very elegant aniseed water. The angelica seeds greatly improve the flavour of the anise. It is often employed with advantage, particularly in cases of flatulent cholera; but it has been alleged to be sometimes too frequently used with this intention as a domestic medicine, especially by old ladies; for unless it be prudently and cautiously employed, it may soon be attended with all the pernicious consequences of dram-drinking.

Spirit of caraway. L.

Take of caraway seeds, bruised, half a pound; proof-spirit, one gallon; water, sufficient to prevent an empyreuma. Draw off one gallon.

Spirituos caraway-water. E.

Take of caraway-seeds, half a pound; proof-spirits nine pounds. Macerate two days in a close vessel; then pour on as much water as will prevent an empyreuma, and draw off by distillation nine pounds.

By this process the spirit obtains in great perfection the flavour of the caraway-seeds; and with some it is a cordial not uncommonly in use.

Spirit of cinnamon. L.

Take of bruised cinnamon one pound; proof-spirits one gallon; water, sufficient to prevent an empyreuma. Draw off one gallon.

Spirituos cinnamon-water. E.

From one pound of cinnamon, nine pounds of spirit are to be drawn off, in the same manner as in the caraway-spirit.

This is a very agreeable and useful cordial, but not so strong of the cinnamon as might be expected; for very little of the virtues of the spice arises till after the pure spirituos part has distilled. Hence, in the former editions of the London pharmacopœia, the distillation was ordered to be protracted till two pints more than here directed were come over. By this means, the whole virtue of the cinnamon was more frugally than judiciously obtained: for the disagreeable flavour of the feints of proof spirits, and the acidulous liquor arising from cinnamon as well as other vegetables when their distillation is long continued, give an ill relish to the whole; at the same time that the oil which was extracted from the spice was by this acid thrown down.

In the Pharmacopœia, Reformata, it is proposed to make this spirit by mixing the simple cinnamon water with somewhat less than an equal quantity of rectified spirit: on shaking them together, the liquor loses its milky hue, soon becomes clear, and more elegant than the water distilled as above: it is equally strong of the cinnamon, and free from the nauseous taint with which the common proof-spirits are impregnated.

Compound spirit of juniper. L.

Take of juniper berries, bruised, one pound; caraway seeds, bruised, sweet-fennel seeds, of each one ounce and a half; proof-spirit, one gallon; water sufficient to prevent an empyreuma. Draw off one gallon.

Compound juniper water. E.

Take of juniper-berries, well bruised, one pound; seeds of caraway, sweet-fennel, each one ounce and a half; proof-spirit, nine pounds; macerate two days; and having added as much water as will prevent an empyreuma, draw off by distillation nine pounds.

This water, mixed with about an equal quantity of the rob of juniper-berries, proves an useful medicine

Preparations and Compositions.

355

356

357

cine

Prepara-
tions and
Composi-
tions.

cine in catarrhs, debility of the stomach and intestines, and scarcity of urine. The water by itself is a good cordial and carminative: the service which this and other spirituous waters do with these intentions is commonly known; though the ill consequences that follow from their constant use are too little regarded.

Spirit of Lavender. L.

358 Take of fresh flowers of lavender, one pound and an half; proof-spirit, one gallon. Draw off by distillation in a water-bath, five pints.

Simple Spirit of Lavender. E.

Take of flowering spikes of lavender, fresh gathered, two pounds; rectified spirit of wine, eight pounds. Draw off by the heat of boiling water seven pounds.

This spirit, when made in perfection, is very grateful and fragrant. It is frequently rubbed on the temples, &c. under the notion of refreshing and comforting the nerves; and it probably operates as a powerful stimulus to their sensible extremities: it is likewise taken internally, to the quantity of a teaspoonful, as a warm cordial.

Spirit of peppermint. L.

359 Take of the herb peppermint, dried, one pound and an half: proof-spirit, one gallon, water, sufficient to prevent an empyreuma. Draw off one gallon.

Spirituous peppermint water. E.

From a pound and a half of these leaves nine pounds of spirit are drawn off, as from the caraway-seeds.

This spirit receives a strong impregnation from the peppermint. It is employed in flatulent colics and similar disorders; and in these it sometimes gives immediate relief: but where it is indicated, there are few cases in which the peppermint-water is not preferable.

Spirit of Spearmint. L.

360 Take of spearmint, dried, one pound and an half; proof-spirit, one gallon; water, sufficient to prevent an empyreuma. Draw off one gallon.

This spirit has no place in the Edinburgh pharmacopœia. It, however, turns out a very elegant one, and preferable, in weakness of the stomach, retching to vomit, and the like, to many more elaborate preparations. Where the disorder is not accompanied with heat or inflammation, half an ounce of this water may be given diluted with some agreeable aqueous liquor; but, as was already observed with regard to the preceding article, there are many cases in which the prudent practitioner will be disposed to give the preference to the simple distilled water.

Spirit of nutmeg. L.

361 Take of bruised nutmegs, two ounces; proof-spirit, one gallon; water, sufficient to prevent an empyreuma. Draw off one gallon.

Spirituous nutmeg-water. E.

By two ounces of the nutmeg, well bruised, nine pounds of spirit are impregnated.

This is an agreeable spirituous liquor, highly impregnated with the nutmeg flavour. It was formerly celebrated in nephritic disorders, and when combined with a few hawthorn flower, it had even the title of *nephritic water*. At present it is employed only as a cordial liquor, and is not even very frequently in use.

Spirit of pimento, or all spice. L.

Take of all spice, bruised, two ounces; proof-spirit one gallon; water, sufficient to prevent an empyreuma. Draw off one gallon.

Spirituous Jamaica pepper water. L.

By half a pound of pimento nine pounds of spirit are to be impregnated.

This water is far more agreeable than a simple water drawn from the same spice; and had long a place among the cordials of the distiller before it was received into any public pharmacopœia; but although now adopted both by the London and Edinburgh colleges, it is not very frequently ordered from the shops of the apothecary.

Spirit of penny-royal. L.

Take of the herb pennyroyal, dried, one pound and an half; proof-spirit one gallon; water sufficient to prevent an empyreuma. Draw off one gallon.

This spirit has no place in the Edinburgh pharmacopœia. It possesses, however, a considerable share of the flavour of the pennyroyal, and very frequently it is employed as a carminative and antihysteric.

Compound spirit of horse-radish. L.

Take of fresh horse radish root, dried outer rind of Seville oranges, each two pounds; fresh herb of garden scurvy-grass, four pounds: bruised nutmegs, one ounce; proof-spirit, two gallons; water, sufficient to prevent an empyreuma. Draw off two gallons.

This spirit has long been considered as an elegant one, and is perhaps as well adapted for the purposes of an antiscorbutic as any thing, that can be contrived in this form. It has been alleged, that the horse-radish and scurvy-grass join very well-together, giving a similar flavour, though not a little disagreeable; that the nutmeg suppresses this flavour very successfully, without superadding any of its own; and that to this, orange-peel adds a flavour very agreeable. Arum root had formerly a place in this water, but is here deservedly thrown out; for it gives nothing of its pungency over the helm, notwithstanding what is asserted by some pharmaceutical writers to the contrary. Mustard-seed, though not hitherto employed in these kinds of compositions, would seem to be an excellent ingredient; it gives over the whole of its pungency, and is likewise less perishable than most of the other substances of this class: this seed wants no addition, excepting some aromatic material to furnish an agreeable flavour.

But although this process may furnish an agreeable compound spirit, yet it is much to be doubted, whether it possess those antiscorbutic powers for which it was once celebrated. And with this intention the Edinburgh college place so little confidence in it, that they have now rejected it from their pharmacopœia.

tions and
Composi-
tions.

362

363

364

Spirit of rosemary.

Take of fresh tops of rosemary, one pound and a half; proof spirit, one gallon. Distil in a water bath, five pints. *L.*

365 Take of flowering tops of rosemary, fresh gathered, two pounds: rectified spirit of wine, eight pints. Distil in the heat of boiling water till seven pounds come over. *L.*

A spirit similar to this is generally brought to us from abroad, under the name of *Hungary water*.

This spirit is very fragrant, so as to be in common use as a perfume: that brought from abroad is superior in fragrance to such as is generally made among us. In order to prepare it in perfection, the vinous spirit should be extremely pure; the rosemary tops gathered when the flowers are full blown upon them, and committed immediately to distillation, care being taken not to bruise or press them. The best method of managing the distillation, is that which was formerly recommended for the distillation of the more volatile essential oils and simple waters, viz. first to place the spirit in the still, and then set in, above the liquor either an iron hoop, with a hair cloth stretched over it, upon which the flowers are to be lightly spread, or rather a basket, supported on three pins, reaching down to the bottom. A gentle heat being applied, just sufficient to raise the spirit, its vapour rightly percolating through the flowers, will imbibe their finer parts, without making that disagreeable alteration, which liquors applied to such tender subjects, in their grosser form, generally do. Probably the superiority of the French Hungary water, to that prepared among us, is owing to some skillful management of this kind, or to employing a perfectly pure spirit.

In the Wirtemberg pharmacopœia, fennel and ginger are added, in the proportion of half a pound of the former, and two ounces of the latter, to four pounds of the rosemary.

But the peculiar agreeable flavour of this water in all probability depends on the rosemary alone.

Carmelite water, or compound balm-water. Dan.

366 Take of fresh gathered leaves of balm, a pound and a half; the recent yellow rind of lemons, four ounces; nutmeg, cardamom, each two ounces; cloves cinnamon, each one ounce. The ingredients being sliced and bruised, pour upon them rectified spirit of wine, six pints; balm-water, three pounds. Digest for three days, then draw off six pounds by distillation.

This spirit has been a good deal celebrated, particularly among the French, under the title of *Lina de Carmes*. Mr Beaumé, in his *Elémens de Pharmacie*, proposes some improvements on the process. After the spirit added to the ingredients has been drawn off in the heat of a water bath, he orders the distilled liquor to be rectified by a second distillation, drawing off somewhat less than nine-tenths of it. He recommends, that all the aromatic spirits should be prepared in the same manner. When the common spirits of this kind are rubbed on the hands, &c. they leave after the more volatile parts have exhaled, a disagreeable empyreumatic smell; and when diluted with water, and taken medicinally, they leave, in like manner, a nauze-

ous flavour in the mouth. To remedy these imperfections, he made many experiments, which showed, that in order to obtain these liquors of the desirable qualities, the spirit must not only be perfectly pure at first, but that the liquor ought also to be rectified after it has been distilled from the subjects. In this rectification, only the more volatile, subtle, aromatic parts of the ingredients arise: there remains behind a white liquor, acrid, bitter, loaded only with the grosser oil, and deprived of all the specific flavour of the subjects. Indeed the very imperfection complained of naturally points out this second distillation as the remedy; for it shows the spirit to contain a grateful and ungrateful matter: the first of which exhales, while the other is left behind. The author says that when the *aqua melissa* is prepared as above directed, it has something in it more perfect than any of the odorous spirits, whose excellence is cried up, and which have the reputation of being the best.

Aromatic spirituous liquors have in general less smell, when newly distilled, than after they have been kept about six months. M. Beaumé suspects that the preparations of this kind which have been most in vogue, were such as have been thus improved by keeping; and found that the good effects of age might be produced in a short time by means of cold. He plunges quart bottles of the liquor into a mixture of pounded ice and sea salt: the spirit, after having suffered, for six or eight hours, the cold thence resulting, proves as grateful as that which has been kept for several years. Simple waters also, after being frozen, prove far more agreeable than they were before, though they are always less so than those which have been drawn with spirit and exposed to a like degree of cold. This melioration of distilled waters by frost was taken notice of by Geoffroy.

Spirit of Scurvy grass. Suec.

Take of fresh scurvy grass, bruised, 10 pounds; rectified spirit of wine, eight pints. With the heat of a water bath, distil off four pints. 367

This spirit is very strong of the scurvy-grass; and has been given in those cases where the use of this herb is proper, from 20 to 100 drops. The virtues of scurvy-grass reside in a very subtle, volatile oil, which arises in distillation both with water and pure spirit; and if the liquors are exposed to the air, soon exhales from both. The spirit, newly distilled, is extremely pungent; but if long kept, even in close vessels, it becomes remarkably less so; but it is not probable that with such a pungent vehicle we can use a sufficient quantity of the herb to produce any permanent or considerable effect; it has been much recommended as a diuretic in dropsies.

The makers of this spirit have frequently added to the scurvy grass a quantity of herb-radish root, and sometimes substituted for it one drawn entirely from the horse-radish: the flavour of these two simples being so much alike that their distilled spirits are scarcely distinguished from each other. Here it may be observed, that though *grum* and *dracunculus* are usually ranked in the same class with the two foregoing vegetables, and considered as similar to them; this process discovers a remarkable difference: while the former

Preparations and Compositions.

yield all their pungency in distillation both to water and spirit; the latter give over nothing to either, and yet their virtues are destroyed in the operation.

Orange-peel water. Succ.

- 268 Take of recent orange skins, one pound; proof-spirit, three pounds. Draw off two pounds by the heat of a water bath.

This spirit, which is now rejected from our pharmacopœias, had formerly a place in them under the title of *aqua corticum aurantium spirituosâ*. It is considerably stronger of the orange-peel than the simple water; and it is used as an useful cordial, stomachic, and carminative.

Aromatic spirit. Succ.

- 369 Take of the tops of rosemary, a pound and an half; tops of milfoil, thyme, each half a pound; proof spirit, 16 pounds; macerate for two days, and draw off by distillation eight pounds. If before distillation eight pounds of vinegar be added, it forms the acetated aromatic spirit.

These preparations do not differ materially from the spirit of rosemary or Hungary water; for on the essential oil of the rosemary their medicinal properties may be considered as chiefly depending. They are often employed, particularly for external purposes, and for impregnating the air with their vapours, to destroy the influence of febrile contagions.

Antiseptic spirit. Gen.

- 370 Take of spirit of turpentine, an ounce and an half; rectified spirit of wine, half a pound. Distil with a gentle heat. Let the oil swimming above in the receiver be separated from the saturated spirit, which is to be preserved for use.

It has been imagined, that this combination of oil of turpentine with ardent spirit will furnish an effectual solvent for biliary calculi. Hence the origin of the name here given it; but although it may have such an effect when copiously applied to the calculi in a glass vessel; yet this is not to be expected when it is taken into the stomach, and can only reach them in the course of circulation.

CHAP. XIX. *Decoctions and infusions.*

- 371 WATER, the direct menstruum of gums and salts, extracts readily the gummy and saline parts of vegetables. Its action, however, is not limited to these; the resinous and oily principles being, in most vegetables, so intimately blended with the gummy and saline, as to be in part taken up along with them: some of the resinous cathartics, and most of the aromatic herbs, as well as bitters and astringents, yield to water the greatest part of their smell taste, and medicinal virtue. Even of the pure essential oils, and odorous resins of vegetables, separated from the other principles, water imbibes a part of the flavour; and by the artificial admixture of gummy or saline matter, the whole substance of the oil or resin is made soluble in water.

Of pure salts, water dissolves only certain determinate quantities: by applying heat, it is generally enabled to take up more than it can do in the cold, and

VOL. XIV.

this in proportion to the degree of heat: but as the liquor cools, this additional quantity separates, and the water retains no more than it would have dissolved without heat. With gummy substance, on the other hand, it unites unlimitedly, dissolving more and more of them till it loses its fluidity. Heat expedites the action of the water, but cannot enable it to take up more than it would do by allowing it longer time in the cold. The active parts extracted from most vegetables by water, and oils and resins made soluble in water by the artificial admixture of gum, partake of this property of pure gums, being soluble without saturation.

It has been imagined, that vegetables in a fresh state, while their oily, resinous, and other active parts are already blended with a watery fluid, would yield their virtues to water more freely and more plentifully than when their native moisture has been dissipated by drying. Experience however, shows that dry vegetables in general give out more than fresh ones, water seeming to have little action upon them in their recent state. If, of two equal quantities of mint, one be infused fresh in water, and the other dried, and then infused in the like quantity of water for the same length of time, the infusion of the dry herb will be remarkably the strongest: and the case appears to be the same in all the vegetables that have been tried.

In all the preparations described in this chapter, it is to be understood that the subjects must be moderately and newly dried, unless when they are expressly ordered to be taken fresh; in which case it is to be judged that their virtues are destroyed or impaired by drying.

The native colours of many vegetables are communicated to water along with their medicinal matter; many impart a colour different from their own; and others, though of a beautiful and deep colour themselves, give scarcely any to the menstruum. Of the first kind are the yellow and red flowers; of the second the leaves of most plants: of the third some of the blue flowers, as those of cyanus and larkspur. Acid liquors change the infusions of most flowers, the yellow ones excepted, to a red; and alkalis, both fixed and volatile to a green.

From animal substances water extracts the gelatinous and nutritious parts; whence glues, jellies, broths, &c.; and along with these, it takes up principles of more activity, as the acrid matter of cantharides. It dissolves also some portion of calcined calcareous earths, both of the animal and of the mineral kingdom, but has no action on any other kind of earthy matter.

The effect of boiling differs from that of infusion in some material particulars. One of the most obvious differences is, that as the essential oils of vegetables, in which their specific odours reside, are volatile in the heat of boiling water, they exhale in the boiling along with the watery steam, and thus are lost to the remaining decoction: whereas both in cold, and sometimes in hot infusions, they are preserved; although in the latter they are by no means perfectly so. Odorous substances, and those in general whose virtues depend on their volatile parts, are therefore unfit for this treatment. The soluble parts of these may, nevertheless, be united in this form with those bodies of a more fixed nature, by boiling the latter till their virtues

Preparations and Compositions.

Prepara-
tion and
Composi-
tion.

tures be sufficiently extracted, and then infusing the former in this decoction.

The extraction of the virtue of the subject is usually promoted or accelerated by a boiling heat; but this rule is less general than it is commonly supposed to be. We have already observed, that Peruvian bark gives out its virtue more perfectly by cold infusion than by coction. In some cases, boiling occasions a premature diffusion of the principles of the subject: thus, when almonds are triturated with cold water, their oil, blended with the mucilaginous or other soluble matter of the almond, unites with the water into a milky liquor called an *emulsion*; but on boiling them in water, the oil separates and rises to the surface; and if the most perfect emulsion be made to boil, a like separation happens.

This also appears to take place, though in a less evident manner, in boiling sundry other vegetables; thus tobacco, asarum, and ipecacuanha, lose their active powers by boiling: nor does it appear that this change is effected merely by the discharge of volatile parts. From some late experiments, it has been found, that the distilled water of ipecacuanha was infinitely less emetic than the infusion from which it was distilled, and that the boiling liquor gradually assumes a black colour, indicating some kind of decomposition of parts: the same circumstances probably take place in boiling tobacco, asarum, and perhaps all vegetables whatever, though from their not producing such sensible operations on the living body, they cannot be so clearly discovered as in ipecacuanha, tobacco, or asarum. The experiments we allude to were made by Dr Irving, when a student in the college of Edinburgh; and they gained him the prize given by the Harveian Society of that place, for the best experimental inquiry concerning ipecacuanha.

It is for the above-mentioned reasons that we think many of the infusions should be made with cold water: it is, however, to be acknowledged, that this is not always absolutely necessary, and in extemporaneous practice it may be often very inconvenient; it is, however, proper to point out the advantages to be expected from this more tedious, but much more complete and elegant, method.

Vinegar extracts the virtues of several medicinal substances in tolerable perfection: but at the same time its acidity makes a remarkable alteration in them, or superadds a virtue of a different kind; and hence it is more rarely employed with this intention than purely aqueous or spirituous menstrua. Some drugs, however, for particular purposes, vinegar excellently assists, or coincides with, as squills, garlic, ammoniac, and others: and in many cases where this acid is itself principally depended on, it may be advantageously impregnated with the flavour of certain vegetables; most of the odoriferous flowers impart to it their fragrance, together with a fine purplish or red colour; violets, for instance, if fresh parcels of them are infused in vinegar in the cold for a little time, communicate to the liquor a pleasant flavour, and deep purplish red colour. Vinegar, like other acids, added to watery infusions or decoctions, generally precipitates a part of what the water had dissolved.

Decoction of marshmallows. E.

Prepara-
tion and
Composi-
tion.

Take of dried marshmallow roots, four ounces; raisins of the sun, stoned, two ounces; water, seven pounds. Boil to five pounds; place apart the strained liquor till the feces have subsided, then pour out the clear liquor.

The Edinburgh college have substituted this for the more complicated formula of the *Decoction ad Nephriticos* of their former pharmacopœia, and it fully answers the intentions of that preparation: it is intended chiefly as an emollient, to be liberally drank of in nephritic paroxysms; in which cases, by softening and relaxing the parts, it frequently relieves the pain, and procures an easy passage for the fabulous matter. This medicine is now made more simple than before, without any diminution of its virtue, by the rejection of wild carrot seed, restharrow root, figs, linseed, and liquorice. The carrot seeds were indeed unfit for this form, as they give out little of their virtue to watery liquors.

Decoction of hartshorn. L.

Take of burnt and prepared hartshorn, two ounces; gum arabic, six drams; distilled water, three pints. Boil constantly stirring, to two pints, and strain.

This decoction is used as common drink in acute diseases attended with a looseness; and where acrimonious humours abound in the prime viæ. The gum is added, in order to render the liquor lightly glutinous, and thus enable it to sustain more of the calx; which is the ingredient on which the colour, but probably not the virtue, of the medicine depends. Calcined hartshorn has no quality from which it seems capable either of constringing and strengthening the vessels, giving a greater degree of consistency to thin fluids, or obtunding acrimonious humours. It blunts and absorbs acid juices; but acrimony and acidity are very different: there are few (perhaps none of the acute) disorders of adults attended with the latter; and few of infants are unaccompanied therewith. Some have proposed starch as an ingredient in these kinds of decoctions; a small quantity of this soft, gelatinous, farinaceous substance would seem to be greatly preferable to the earthy calx. It may be observed, that the water is not enabled by the boiling to dissolve any part of the calx; and that in the decoction, the earth is only diffused in substance through the water, as it would be by agitation.

For these reasons, this formula is now rejected by the Edinburgh college, notwithstanding the reputation in which it was held by Dr Sydenham, and other names of the first eminence. But as an absorbent of a similar nature, the Edinburgh college have introduced the following formula.

Chalk julap. E.

Take of prepared chalk, one ounce; purest refined sugar, half an ounce; mucilage of gum arabic, two ounces; rub them together; and add by degrees, water, two pounds and a half; spirituous cinnamon water, two ounces. Mix them.

In the former edition of the Edinburgh pharmacopœia,

Prepara-
tions and
Composi-
tions.

poëia, a preparation of this kind had the title of *d'coctum cretaceum*, and the chalk was directed to be boiled with the water and gum. In the present formula, the chalk is much more completely suspended by the mucilage and sugar, which last gives also to the mixture an agreeable taste; it is proper to employ the finest sugar, as the redundant acid in the coarser kinds might form with the chalk a kind of salt. It would perhaps have been more proper to have added an aromatic, by suspending the entire powder of cinnamon, or its oil, by means of the mucilage and sugar; the method here directed is, however, less exceptionable in this than in many other preparations, as the precipitated matter of the spirituous water will probably be inviscated in the saccharine and mucilaginous matter. This is a very elegant form of exhibiting chalk, and is an useful remedy in diseases arising from, or accompanied with, acidity in the primæ viæ. It has been most frequently employed in fluxes proceeding from that cause. At the same time that the mucilage serves to keep the chalk uniformly diffused, it also considerably improves its virtues by sheathing the internal surface of the intestines so often abraded in these affections. It is indeed probable, that chalk, as being somewhat astringent, is in some of these complaints preferable to magnesia; both, however, are improper in dysentery, or other fluxes attended with putrescent matter in the primæ viæ, or a general tendency to a putrefaction of the fluids.

Decoction of Peruvian bark. L.

- 375 Take of Peruvian bark, powdered, one ounce; distilled water, one pint and three ounces. Boil, for ten minutes, in a covered vessel, and strain the liquor while hot.

Although a cold watery infusion of bark is in general preferable to any decoction, yet this form has at least the advantage of being more quickly prepared. And the decoction here directed, which is boiled only for a short time, and strained while hot, is preferable to any other.

This decoction should be passed only through a coarse strainer, and drank while turbid: if suffered to stand till clear, the more efficacious parts of the bark will subside. We have formerly observed, that the virtues of this drug consist chiefly in its resinous substance, which, though it may be totally melted out by the heat of boiling water, remains only partially suspended in that menstruum.

Decoction for a clyster. L.

- 376 Take of the dried leaves of mallow, one ounce; dried camomile-flowers, half an ounce; water, one pint. Boil and strain.

The title of this decoction sufficiently expresses its use, as the basis of glysters. The ingredients should be very lightly boiled, or at least the camomile flowers should not be put in till towards the end, a part of their virtue being soon lost by boiling.

Decoction for fomentation. L.

- 377 Take of the dried leaves of fotherwood, the dried tops of sea-wormwood, dried camomile flowers, each one ounce; dried bay-leaves, half an ounce; distilled water six pints. Boil them a little, and strain.

Common decoction. L.

Take of camomile flowers, one ounce; carvy seed, half an ounce; water, five pounds. Boil for a quarter of an hour, and strain.

This decoction is intended to answer the purposes of both the foregoing. It is less loaded with ingredients than either, but not perhaps for that reason the less useful.

It is indeed to be acknowledged, that these impregnations are for the most part unnecessary for the purpose of glysters; and in ordinary cases the weight of the water usually solicits a discharge before these medicines can produce any effect.

As to fomentations, their virtues in our opinion are totally to be ascribed to the influence of the warm water. And when the herbs themselves are applied, they act only as retaining heat and moisture for a longer time.

Decoction of hellebore. L.

Take of the root of white hellebore, powdered, one ounce; distilled water, two pints; rectified spirit of wine, two ounces. Boil the water with the root to one pint; and, the liquor being cold and strained, add to it the spirit.

White hellebore, as we formerly observed, is now very rarely employed internally; and the present formula is entirely intended for external use. Recourse is sometimes had to it with advantage in cutaneous eruptions, particularly in tinea capitis. But where the incrustations are entirely removed, leaving a very tender skin, it is necessary that the decoction should be diluted previous to its employment.

Decoction of barley. L.

Take of pearl barley, two ounces; distilled water, four pints. The barley being first washed with cold water from the adhering impurities, pour upon it about half a pint of water, and boil the barley a little time. This water being thrown away, add the distilled water, boiling, to the barley; boil it to two pints, and strain.

Compound decoction of barley. L.

Take of the decoction of barley, two pints; raisins, stoned, figs, sliced, each two ounces; liquorice-root, sliced and bruised, half an ounce; distilled water one pint. Boil to two pints, and strain.

Barley-water. E.

Take of pearl-barley, two ounces; water, five pints. First wash the barley from the mealy matter that adheres to it with some cold water; then boil it a little with about half a pint of fresh water, which will acquire a considerable tinge from it. Throw away this tinged water; put the barley into the five pints of boiling water prescribed; and continue the boiling till half the water be wasted.

These liquors are to be drank freely as a diluter, in fevers and other disorders; hence it is of consequence that they should be prepared so as to be as elegant and agreeable as possible; for this reason they are inserted in the pharmacopœia, and the several circumstances which contribute to their elegance set down; if any one of them be omitted, the beverage will be less grate-

Preparations and Compositions.

ful. However trivial medicines of this class may appear to be, they are of greater importance in the cure of acute diseases than many more elaborate preparations.

Barley-water, however, is much more frequently prepared by nurses than apothecaries, particularly in its simple state. The compound decoction contains a large proportion of saccharine and mucilaginous matter, and may be employed for the same purposes as the decoction of marshmallows of the Edinburgh pharmacopœia.

Decoction of the woods. E.

- 383 Take of guaiacum saw-dust, three ounces; raisins of the sun, stoned, two ounces; saffras wood, shaved, liquorice sliced, each one ounce: water, ten pounds. Boil the guaiacum and raisins with the water, over a gentle fire, to the consumption of one half; adding, towards the end, the saffras and liquorice. Strain out the liquor; and having suffered it to rest for some time, pour off the clear from the feces without expression.

This decoction is very well contrived; and if its use be duly continued, it will do great service in some cutaneous diseases, in what has been called foulness of the blood and juices, and in some disorders of the breast; particularly in phlegmatic habits. It may be taken by itself to the quantity of a quarter of a pint two or three times a-day, or used as an assistant in a course of mercurial or antimonial alteratives; the patient in either case keeping warm, in order to promote the operation of the medicine. The saw-dust exposes a larger surface to the action of the water than the shavings, directed in the former edition of the pharmacopœia.

Decoction of sarsaparilla. L.

- 384 Take of the root of sarsaparilla, sliced, six ounces; distilled water, eight pints. Macerate for two hours, with an heat of about 195°; then take out the root, and bruise it; return the bruised root to the liquor, and again macerate it for two hours. Then, the liquor being boiled to four pints, press it out, and strain.

This decoction is an article in very common use, particularly in venereal affections. And there can be little doubt, that by this process the medical powers of the sarsaparilla are fully extracted. But it has of late been much questioned, whether this article be in any degree intitled to the high character which was once given of it. Some, as we have already observed, are even disposed to deny its possessing any medical property whatever: but the general opinion is, that it has somewhat of a diaphoretic effect; and this effect is more readily obtained when it is exhibited under the form of decoction than under any other.

Compound decoction of sarsaparilla. L.

- 385 Take of the root of sarsaparilla, sliced and bruised, six ounces; bark of the root of saffras, raspings of guaiacum-wood, liquorice root, bruised, of each one ounce; bark of the root of mezercon, three drams; distilled water, ten pints. Macerate, with a gentle heat, for six hours; then boil it down to five pints, adding, towards the end, the bark of the root of mezercon, and strain the liquor.

This compound decoction is an elegant mode of preparing an article once highly celebrated under the title of the *Lisbon diet drink*. That formula, for a long time after its first introduction into Britain, was kept a secret; but an account of the method of preparation was at length published in the Physical and Literary Essays of Edinburgh, by Dr Donald Monro. And of the formula there given, which is in many respects an unchemical one, the present may justly be considered as an improvement. Even in its original form, but still more in the present state, there can be no doubt, that it furnishes us with a very useful medicine, particularly in those obstinate ulcers originating from venereal infection, which resist the power of mercury. And it is highly probable, that its good effects principally depend on the impregnation it receives from the mezercon. Perhaps, however, even thus improved, it is more complicated and expensive than is necessary: at least we are inclined to think, that every advantage derived from it may with equal ease and certainty be obtained from impregnating with the mezercon, in the manner here directed, a simple decoction of the guaiacum, bardana, or althæa, without having recourse to several articles, or employing one so expensive as the sarsaparilla.

Decoction of feneka. E.

- Take of feneka, or rattlesnake root, one ounce; water, two pounds. Boil to sixteen ounces, and strain. 386

The virtues of this decoction will be easily understood from those of the root from which it is prepared. The dose, in hydropic cases, and rheumatic, or arthritic complaints, is two ounces, to be repeated three or four times a-day, according to its effect.

Decoction of elm. L.

- Take of the fresh inner bark of elm, bruised, four ounces; distilled water, four pints. Boil to two pints, and strain. 387

It has been chiefly, if not entirely, under this form of decoction, that the elm-bark has been employed for combating those cutaneous eruptions against which it has of late been so highly celebrated. Any experience which we have had of it, however, in actual practice, by no means confirms the very favourable account which some have given of its use.

Mucilage of starch. L.

- Take of starch, three drams; distilled water, one pint. Rub the starch, by degrees adding the distilled water; then boil it a little time. 388

The mucilage thus formed of starch is very useful for answering these purposes where a glutinous substance is required, and in particular it is often successfully employed under the form of glyster.

Mucilage of gum arabic.

- Take of gum arabic, powdered, four ounces; boiling distilled water, eight ounces. Rub the gum with the water till it be dissolved. L. 389

Take of gum arabic, beat into powder, and warm water, each equal weights. Digest, and frequently stir them till the gum be dissolved, then press the solution through linen. E.

Preparations and Compositions.

It is very necessary to pass the mucilage through linen, in order to free it from pieces of wood and other impurities, which always adhere to the gum; the linen may be placed in a funnel.

Mucilage of gum arabic is very useful in many operations in pharmacy: it is also much used for properties peculiar to those substances of its own class, and of all the gums it seems to be the purest.

Mucilage of gum tragacanth. E.

- 390 Take of gum tragacanth, powdered, one ounce; hot water, eight ounces. Macerate twenty-four hours; then mix them, by rubbing briskly, that the gum may be dissolved; and press the mucilage through linen cloth.

This gum is more difficultly soluble in water than gum arabic, and seems to be considerably more adhesive; it is therefore fitter for forming troches, and such like purposes. It has been thought to be more peculiarly what has been called a *pectorals*, than the other gums: but this does not seem to be certainly founded. This mucilage is perhaps preferable to the foregoing in those operations in pharmacy where much tenacity is required; as in the suspension of mercury, or other ponderous bodies.

Mucilage of quince-seed. L.

- 391 Take of seeds of the quince, one dram; distilled water, eight ounces, by measure. Boil with a slow fire until the water thickens; then pass it through linen.

This is a pleasant soft mucilage, of a somewhat sweetish taste, and a light agreeable smell: in these respects, and in its easy solubility in water, it differs from the mucilage of gum tragacanth, to which some have supposed it similar: it has another difference, to its disadvantage, being apt to grow mouldy in keeping.

Compound infusion of gentian. L.

- 392 Take of the root of gentian, one dram: fresh outer-rind of lemons, half an ounce; dried outer rind of Seville oranges, one dram and an half. Boiling water, 12 ounces, by measure. Macerate for an hour, and strain.

Bitter infusion. E.

Take of gentian root, half an ounce; dried peel of Seville oranges, one dram; coriander seeds, half a dram; proof-spirit, four ounces; water, one pound. First pour on the spirit, and three hours thereafter add the water; then macerate without heat for a night, and strain.

These formulæ do not materially differ. That of the London college is the most expeditious mode of preparation; but that of the Edinburgh college possesses other advantages, which are in our opinion more than sufficient to outweigh that circumstance.

In the former edition of the Edinburgh pharmacopœia the water was directed to be boiling: this was at least unnecessary, and was probably liable to the objections observed against decoctions. The proof-spirit is also an useful addition to the bitter infusion, as it now stands in the Edinburgh pharmacopœia: besides that it assists in extracting the resinous parts, and pre-

paring the infusion for fermentation, it communicates an agreeable pungency to the liquor. To answer in some measure these intentions, it was formerly directed to add to the filtrated liquor a quantity of aromatic water. This was certainly a piece of very bad pharmacy; for, besides that the spirit in this preparation, when diluted with the water of the infusion, was now no longer able to retain the suspended matter, it would also dispose the infusion to part with its proper extractive matter; and in this way the resinous matter of the aromatic water, and the gummy parts of the bitter infusion, would both in some degree separate to the bottom of the vessel. By the formula now laid down, the infusion contains the different principles of the ingredients in a manner more nearly approaching to their natural and entire state.

Simple infusion of fenna. L.

Take of fenna one ounce and a half; ginger, powdered, one dram; boiling distilled water, one pint. Macerate them for an hour in a covered vessel; and the liquor being cold, strain it.

This, although a simple, is a very elegant infusion of fenna, the ginger acting as an useful corrigent. But if the fenna were employed to the quantity of a dram and an half or two drams only, with the same menstruum, in place of the quantity here ordered, it would be a no less useful medicine, and might be employed for one dose, as it is best when fresh. Of the present infusion, an ounce or two is a sufficient dose.

Tartarized infusion of fenna. L.

Take of fenna, one ounce and a half; coriander seeds, bruised, half an ounce; crystals of tartar, two drams; distilled water, one pint. Dissolve the crystals of tartar by boiling in the water; then pour the water, as yet boiling, on the fenna and seeds. Macerate for an hour in a covered vessel, and strain when cold.

In the last edition of the London pharmacopœia this had the name of *infusum fennæ commune*.

Formerly an alkaline salt was used in the infusion of fenna instead of the acid one here directed. The first was supposed to promote the operation of the medicine, by superadding a degree of purgative virtue of its own, and by enabling the water to extract somewhat more from the capital ingredient than it would be capable of doing by itself; while acids were alleged to have rather a contrary effect. Experience however has sufficiently shown, that alkaline salts increase the offensiveness of the fenna, while crystals of tartar considerably improve the colour of the infusion, and likewise render the taste to some persons less disagreeable. Soluble tartar should seem a good ingredient to these kinds of compositions, as it not only improves the taste, but promotes the purgative virtue of the medicine: this addition also renders the infusion less apt to gripe, or occasion flatulencies.

Infusion of tamarinds with fenna. E.

Take of tamarinds, six drams; crystals of tartar, fenna, each one dram; coriander seeds, half a dram; brown sugarcandy, half an ounce; boiling water, eight ounces. Macerate in a close earthen vessel which has not been vitrified with lead; stir the liquor now,

Preparations and Compositions.

393

394

395

and then, and after it has stood four hours strain it.

It may also be made with double, triple, &c. the quantity of fenna.

Both this and the former infusions might be made with cold water. By this means the aromatic quality of the coriander seeds would probably be extracted in a more perfect state; but the crystals of tartar are so difficultly soluble in cold water, that for extemporaneous use it is in some measure necessary to prepare them in the manner here directed. It is not indeed probable that when such soluble matters as acids and sugar are presented to water, the water shall be able to extract such a quantity of the finer volatile part of aromatics as to afford any considerable flavour to the liquor. Where an aromatic is required, we would therefore propose, that some agreeable aromatic water should be mixed with the liquor immediately before swallowing it; or that a quantity of aromatic oil should be incorporated with the cold infusion by means of gum, or a part of the sugar which might be reserved for that purpose. It is a very necessary caution not to make this infusion in vessels glazed with lead, otherwise the acid might corrode the lead, and communicate its poisonous effects to the infusion.

Both these infusions are mild and useful purges; the latter in particular is excellently suited for delicate stomachs at the same time that it is very much calculated for febrile and other acute diseases. It is observable, that sugar added to neutral salts rather increases than diminishes their nauseousness; but when used along with an acid, such as tamarinds, or a salt wherein the acid predominates, as in crystals of tartar, it is found very much to improve their taste. The acid in this infusion, or rather the combination of acid and sweet, are found to cover the taste of the fenna very effectually: the aromatic serves also the same purpose, but would perhaps be better applied in the way above proposed.

Infusion of the rose. L.

395 Take of red rose-buds, the heels being cut off, half an ounce; vitriolic acid, diluted three drams; boiling distilled water two pints and a half; double-refined sugar one ounce and a half. To the water first poured on the petals in a glass vessel, add the diluted vitriolic acid and macerate for half an hour. Strain the liquor when cold, and add the sugar.

Infusion commonly called tincture of roses. E.

Take of red roses, dried, one ounce; boiling water, five pounds; vitriolic acid, one dram; white sugar, two ounces. Macerate the roses with the boiling water in an unglazed vessel four hours; then having poured on the acid, strain the liquor, and add the sugar.

Some have directed the vitriolic acid to be dropped upon the roses before the water is put to them; but this method is certainly faulty; for such of the roses as this caustic liquor falls on undiluted will be burnt up by it, and have their texture destroyed. Others have made an infusion of the roses in water first, and then added the acid, from an apprehension, that if this acid be added to the water, it would weaken its power as a menstruum; but whatever the acid spirit will hinder the water from extracting, it must precipitate

if added afterwards; though, in this preparation, the vitriolic acid bears so small a proportion to the water, that its effects in this respect will be very little; and it appears to be of so little consequence which of the two ways be followed, only that by the above formula the vessels are exposed a shorter time to the action of the acid. The infusion should be made in a glass or stone-ware vessel, rather than a glazed earthen one; for the acid will be apt to corrode the glazing of the latter.

This infusion is of an elegant red colour, and makes a very grateful addition to juleps in hæmorrhagies, and in all cases which require coolers and subastringents. It is sometimes taken with boluses or electuaries of the bark, and likewise makes a good gargle. But although in our pharmacopœias it has its name from the roses, yet its virtues are to be ascribed chiefly, or perhaps solely to the vitriolic acid.

Infusion of rhubarb. E.

Take of rhubarb half an ounce; boiling water, eight ounces; spirituous cinnamon water, one ounce. Macerate the rhubarb in a glass vessel with the boiling water for a night, then having added the cinnamon water, strain the liquor.

397

In this infusion cold water might perhaps be employed with advantage; we also object to the spirituous cinnamon-water on the same grounds as we did before to the aromatic water in the bitter infusion of the former Edition of the Edinburgh pharmacopœia. This, however, appears to be one of the best preparations of rhubarb when designed as a purgative; water extracting its virtue more effectually than either vinous or spirituous menstrua. In this respect rhubarb differs from most of the other vegetable cathartics; and we think the London college might have given it a place in their pharmacopœia as well as wine or tincture of rhubarb.

Lime water.

Take of quicklime, half a pound: boiling distilled water, twelve pints. Mix, and set it aside in a covered vessel for an hour; then pour off the liquor, which keep in a close vessel. L.

398

Take half a pound of fresh burnt quicklime, put it into an earthen vessel, and gradually sprinkle on it four ounces of water, keeping the vessel shut while the lime grows hot and falls into powder; then pour on it twelve pounds of water, and mix the lime thoroughly with the water by stirring. After the lime has subsided renew the stirring; and let this be done about ten times, always keeping the vessel shut (during the ebullition), that the access of the air may be the more effectually prevented. Lastly, let the water be filtered through paper placed in a funnel close shut at its top; and it must be kept in very close vessels. E.

The reason of adding the water by degrees to the lime is, that when poured on at once it reduces the external part to a kind of muddy substance, or soft paste, which in some measure defends the internal part from being acted on by the water. It does not appear that the different proportions of water in the two above prescriptions occasion any sensible difference in the strength of the product: the quicklime is far from yielding all its soluble parts to either proportion; the remainder

Prepara-
tions and
Composi-
tions.

remainder giving a strong impregnation to many fresh quantities of water, though not so strong as to the first. The caution of keeping the water in close-stopped vessels ought to be strictly attended to; for in open ones the calcareous matter dissolved in the liquor soon begins to separate, and forms a white crust on the surface. This crust is not of a saline nature, as some have imagined; but an insipid earth, no longer miscible with watery liquors. The theory of the production of this earth will be easily understood from what we have said on the article *FIXED AIR*. The separation first takes place at the surface, as being the part immediately applied to the common air. As long as the crust remains entire, the closeness of its texture so excludes the air, that the rest of the matter still remains impregnated with lime; but when this pellicle is broken by any means, it soon sinks to the bottom, and exposes a new surface for the separation of the lime. In this way a succession of crusts and precipitations are formed, till the whole of the once caustic and soluble quicklime is now found at the bottom of the vessel in the state of a mild insoluble earth, leaving the water perfectly insipid.

The formation of these crusts, and their successive precipitations, are owing to the absorption of fixed air, or aerial acid, from the atmosphere; and the mild insoluble state of these precipitations is also owing to the same cause.

The distilled water recommended by the London college is certainly preferable to common fountain water; the purity of which can rarely be depended on.

Lime-water has been thought of great service in serofulous complaints; but perhaps on no very good foundation. It has also been used both internally and externally for various affections of the skin. It seems to be very considerably astringent, and has been useful in some kinds of alvine fluxes, in diabetes, leucorrhœa, and in sundry other disorders proceeding from a laxity or debility of the solids.

Its more common use is in affections of the stomach accompanied with acidity and flatulence. For which last complaint, the mild or aerated earths are less proper, on account of the separation of air on their meeting with an acid in the stomach. Lime-water is also capable of dissolving mucus; and may therefore be used where a redundancy of the intestinal mucus affords a nidus for worms, or gives rise to other complaints. It has also been found, that lime-water injected into the anus immediately kills ascarides. The lithontriptic powers of lime-water seem at present to be much doubted. Lime-water is given in doses proportioned to the nature of the complaints: in some cases, as in diabetes, it may be given in divided portions to the extent of two quarts a-day. It is used externally for washing what are called *soul* or *ill-conditioned ulcers*; it is also injected into the vagina and other parts affected with preternatural discharges from laxity.

The use of lime-water in scurvy is very doubtful.

Vinegar of squills.

399 Take of squills, dried, one pound; vinegar six pints; proof-spirit, half a pint. Macerate the squills in the vinegar with a gentle heat, in a glass vessel, for four-and-twenty hours; then press out the li-

quor, and set it by that the feces may subside; lastly, pour off the liquor, and add to it the spirit. *L.* Take of dried, root of squills, two ounces, distilled vinegar, two pounds and a half; rectified spirit of wine, three ounces. Macerate the squills with the vinegar eight days; then press out the vinegar, to which add the spirit; and when the feces have subsided, pour off the clear liquor. *E.*

Vinegar of squills is a medicine of great antiquity; we find in a treatise attributed to Galen, an account of its preparation, and of many particular virtues ascribed to it. It is a very powerful stimulant, aperient, and what is called an attenuant of tenacious juices; and hence it is frequently used, with great success, in disorders of the breast occasioned by a load of thick phlegm, and for promoting urine in hydropic cases. The dose of this medicine is from a dram to half a pint: where crudities abound in the first passages, it may be given at first in a larger dose, to evacuate them by vomiting. It is most conveniently exhibited along with cinnamon, or other agreeable aromatic waters, which prevent the nausea it would otherwise, even in small doses, be apt to occasion,

Aromatic vinegar. Succ.

Take of tops of rosemary, leaves of sage, each four ounces; flowers of lavender, two ounces; cloves two drams; vinegar; eight pounds. Macerate for four days, express the liquor, and strain it.

400

This may be considered as an elegant improvement of what had formerly a place in the foreign pharmacopœias, under the title of *acetum prophylacticum*, which contained not only the present articles, but also a confused farrago of others, as wormwood, rue, garlic, cinnamon, &c.

It is said, that during the plague at Marseilles, four persons, by the use of the *acetum prophylacticum* as a preservative, attended, unhurt, multitudes of those who were infected: that under colour of those services, they robbed both the sick and the dead; and that one of them being afterwards apprehended, saved himself from the gallows by discovering the remedy. The preparation was hence called *Vinaigre des quatre voleurs*; "The vinegar, of the four thieves." It is not to be doubted that vinegar impregnated with antiseptic vegetables, will contribute greatly to prevent the effects of contagious air. And in the present aromatic vinegar we have a stronger and better impregnation, than from the numerous articles which were before employed. We are far, however, from imagining that it will be able to counteract the contagion of the plague; but it may on different occasions be more powerful than vinegar in its simple state, for impregnating with antiseptic vapours the chambers of the sick.

Vinegar of roses. Succ.

Take of the flowers of red roses dried, any quantity; add to them twelve times their weight of vinegar. Macerate for four days, and strain through paper.

401

This has been chiefly used for embrocating the head and temples in some kinds of headach, &c. in which it has now and then been of service. It has also been used for certain cases of ophthalmia. But before it

can be applied to the eyes, it will in general require to be diluted with water.

Vinegar of lead. Succ.

402

Take of litharge, triturated, half a pound; vinegar, two pounds. Digest them together, frequently stirring the mixture with a wooden rod, till the colour of blue paper be not changed by the vinegar; preserve for use the clear liquor which is above the sediment.

This liquor is of the same nature with solutions of sugar of lead, or acetated ceruse, as it is now called. It is only externally against cutaneous eruptions, redness, inflammations, &c. But even in these cases some think it is not void of danger: and it is alleged, that there are examples of its continued use having occasionedundry ill consequences. Of this, however, we are very doubtful. By means of the acetated ceruse every purpose to be answered by this may be accomplished. This liquor differs only in the proportions from the water of acetated litharge of the London pharmacopœia.

Vinegar of colchicum. Ros.

403

Take of the recent root of colchicum cut into slices, one ounce; vinegar, one pound. Macerate with a gentle heat for two days: then strain after slight expression.

Although in our pharmacopœias a place be given to the oxymel and syrup of colchicum, both of which are formed from the vinegar, yet the vinegar itself is not directed to be kept in its separate state; under this form, however, it may often be employed with advantage.

Infusion of Peruvian bark. Succ.

404

Take of Peruvian bark, bruised, an ounce and a half; river water, boiling, a pound and a half. Digest for two hours, shaking the vessel frequently; then strain the liquor with expression.

The Peruvian bark, as we have already had occasion to observe, gives out its medical properties to water not less readily in the way of infusion than of decoction. And in the former, the extractive matter is even more in a state of solution. An infusion, however not only more elegant, but stronger than the present, might be obtained, from employing cold instead of boiling water, and from continuing the maceration for a greater length of time. But in whatever manner it be formed, an infusion will often sit on the stomach, when the bark either in substance or decoction cannot be retained.

Tar-water. Succ.

405

Take of tar two pounds; water, one gallon. Stir them strongly together with a wooden rod; and after standing to settle for twelve hours, pour off the water for use.

Tar-water has lately been recommended to the world as a certain and safe medicine in almost all diseases; a slow yet effectual alterative in cachexies, scurvy, chlorotic, hysterical, hypochondriacal and other chronic complaints; and a sudden remedy in acute distempers which demand immediate relief, as pleuritis,

peripneumonies, the small-pox, and all kinds of fevers in general. The medicine, though certainly far inferior to the character that has been given of it, is doubtless in many cases of considerable utility: it sensibly rouses the pulse; and occasions some considerable evacuation, generally by perspiration or urine, though sometimes by stool or vomit. Hence it is supposed to act by increasing the vis vitæ, and enabling nature to expel the morbid humours.

We shall here insert, from the first public recommender of this liquor (Bishop Berkeley), some observations on the manner of using it. "Tar-water, when right, is not paler than French, nor deeper coloured than Spanish, white wine, and full as clear; if there be not a spirit very sensibly perceived, in drinking, you may conclude the tar-water is not good. It may be drank either cold or warm. In colics, I take it to be best warm. As to the quantity, in common chronical indispositions, a pint a-day may suffice, taken on an empty stomach, at two or four times, viz. night and morning, and about two hours after dinner and breakfast; more may be taken by stonger stomachs. But those who labour under great and inveterate maladies, must drink a greater quantity, at least a quart every twenty-four hours. All of this class must have much patience and perseverance in the use of this, as well as of all other medicines, which, though sure, must yet in the nature of things be slow in the cure of inveterate chronical disorders. In acute cases, fevers of all kinds, it must be drank in bed warm, and in great quantity (the fever still enabling the patient to drink), perhaps a pint every hour, which I have known to work surprising cures. But it works so quick, and gives such spirits, that the patients often think themselves cured before the fever has quit left them."

Notwithstanding these encomiums, tar-water seems to be fast losing its reputation. It is not probable that water can take up any of the more active principles of the tar; and it would perhaps be more convenient to separate its acid by distillation, and mix it with water occasionally: for it is pretty certain, that the water can only take up the acid of the tar, perhaps charged with a very small quantity of oily matter in the state of an acid soap.

Decoction of catechu. Gen.

406

Take of catechu, three drams: spring water, two pounds: boil it to one pound; and add to the strained liquor, of syrup of quinces, three ounces.

This decoction may be considered as nearly similar to the decoctum japonicum, and decoctum terræ japonicæ of the former editions of our pharmacopœia: and like these it will be found a very agreeable and useful medicine in fluxes that are not critical or symptomatic, and in a weak lax state of the intestines. A spoonful or two may be taken every hour, or oftener: thus managed it produces much better effects than if larger doses are given at once. But for extracting the powers of the catechu, boiling is not requisite. By simple infusion in warm water, all its active parts are readily and completely dissolved. It may in this manner also be readily united with cinnamon or other aromatics. And an infusum japonicum is, we think, a formula justly intitled to a place in our pharmacopœias.

407

THE original intention of medicated wines was, that medicines, which were to be continued for a length of time, might be taken in the most familiar and agreeable form: by this means a course of remedies was complied with, notwithstanding the repugnance and aversion which the sick often manifest to those directly furnished from the shops; and hence the inferior sort of people had their medicated ales. Nevertheless, as vinous liquors excellently extract the virtues of several simples, and are not ill fitted for keeping, they have been employed as officinal menstrua also; and substances of the greatest efficacy are trusted in this form. As compounds of water and inflammable spirit, they take up such parts of vegetables and animals as are soluble in those liquors; though most of them abound at the same time with a mucilaginous or viscous substance, which renders them less effectual menstrua than purer mixtures of water and spirit. They contain likewise a subtil acid, which somewhat further obstructs their action on certain vegetable and animal matters; but enables them in proportion to its quality, to dissolve some bodies of the metallic kind, and thus impregnate themselves with the corroborating virtues of steel, the alterative and emetic powers of antimony, and the noxious qualities of lead.

To all the medicated wines, after they have been strained, you may add about one twentieth their quantity of proof spirit, to preserve them from fermentation. They may be conveniently kept in the same kind of glass bottles that wines generally are for common uses, which should likewise be corked with the same care.

Wine of aloes. L.

408

Take of focotorine aloes, eight ounces; white canella, commonly called *winter's bark*, two ounces; Spanish white wine, six pints; proof spirit, two pints. Powder the aloes and white canella separately; when mixed, pour on them the wine and spirit: afterwards digest for fourteen days, now and then shaking them; lastly, strain. It will not be amiss to mix white sand, cleansed from impurities, with the powder, in order to prevent the moistened aloes from getting into lumps.

Aloetic wine, or sacred tincture. E.

Take of focotorine aloes, one ounce; lesser cardamom seeds, ginger, each one dram; Spanish white wine, two pounds. Digest for seven days, stirring now and then, and afterwards strain.

This medicine has long been in great esteem, not only as a cathartic, but likewise as a stimulus; the wine dissolving all that part of the aloes in which these qualities reside, a portion only of the less active resinous matter being left. The aromatic ingredients are added to warm the medicine, and somewhat alleviate the ill flavour of the aloes: white canella, or cloves, are fluid, among numerous materials that have been tried, to answer this end the most successively; hence the introduction of the former of these into the formula of the London college.

VOL. XIV.

The sacred tincture appears from long experience to be a medicine of excellent service in languid, phlegmatic habits, not only for cleansing the primæ viæ, but likewise for stimulating the solids, warming the habit, promoting or exciting the uterine purgations, and the hæmorrhoidal flux. The dose, as a purgative, is from one to two ounces or more. It may be introduced into the habit, so as to be productive of excellent effects, as an alterant, by giving it in small doses, at proper intervals: thus managed, it does not for a considerable time operate remarkably by stool; but at length proves purgative, and occasions a lax habit of much longer continuance than that produced by the other common cathartics.

Bitter wine. E.

Take of root of gentian, half an ounce; Peruvian bark one ounce; Seville orange-peel, dried, two drams; white canella one dram; proof spirit four ounces; Spanish white-wine, two pounds and a half. First pour on the spirit, after twenty-four hours add the wine; then macerate for three days, and strain.

This wine is intended to supply the place of the stomachic tincture, as it was formerly called. The wine is a menstruum fully capable of extracting the active powers of the different ingredients; and it supplies us with a very useful and elegant stomachic medicine, answering the purposes intended much better than the celebrated elixir of Van Helmont, and other unchemical and uncertain preparations, which had formerly a place in our pharmacopœias.

Wine of antimony. L.

Take of vitrified antimony powdered, one ounce; Spanish white wine, a pint and an half. Digest for twelve days, frequently shaking the vessel, and filter the wine through paper.

Antimonial wine. E.

Take of glass of antimony, finely powdered, one ounce; Spanish white wine, fifteen ounces. Macerate for three days, stirring them now and then, and afterwards strain the liquor through paper.

However carefully the settling and decantation are performed, the filtration of the wine through paper appears to be necessary, lest some of the finer parts of the glass should chance to remain suspended in substance. It is not here, as in most other wines and tinctures, where the matter left undissolved by the menstruum is of little consequence; the antimonial glass, after the action of the wine, continues as virulent as ever, and capable of impregnating fresh parcels of the liquor as strongly as the first, and this in appearance, inexhaustibly. After thirty repeated infusions, it has been found scarce sensibly diminished in weight.

The antimonial wine possesses the whole virtues of that mineral, and may be so dosed and managed as to perform all that can be effected by any antimonial preparation; with this advantage, that as the active part of the antimony is here already dissolved and rendered miscible with the animal fluids, its operation is more certain. Given from ten to fifty or sixty drops, it generally acts as an alterative and diaphoretic, in larger doses as a diuretic and cathartic; while three or four drams prove for the most part violently emetic.

3 D

It

It has been chiefly used with this last intention, in some maniacal and apoplectic cases; and hence it gained the name of *emetic wine*.

The quantity of the reguline part must however, vary according to the proportions of the acid matter in different wines, and the operation of the medicine must be thereby less certain in degree; the vitrum is preferable to the erocus for making this preparation. See the different preparations of *Antimony*.

Wine of tartarized antimony. L.

- 411 Take of tartarized antimony, two scruples; boiling distilled water, two ounces; Spanish white wine, eight ounces; dissolve the tartarized antimony in the boiling distilled water, and add the wine.

Wine of antimonial tartar. E.

Take of antimonial tartar, commonly called *emetic tartar*, twenty-four grains; and dissolve it in a pound of Spanish white wine.

Watery solutions of emetic tartar, on standing, precipitate a part which is less completely in a saline state; by this means, and especially if the solution be not shaken before using it, the dose of that medicine is somewhat ambiguous: in the above formula, the acid matter of the wine increases the saline state of the antimony, and therefore its solubility, whereby the operation of the medicine is more certain, and in many cases more powerful. From the certainty of its effects, this preparation might be very convenient in large hospitals or armies, where great numbers of the sick, and inaccurate nursing frequently occasion an uncertain or dangerous practice.

In the formula employed by the Edinburgh college, each ounce of the wine contains two grains of the tartarized antimony; but in that of the London college, each ounce of the menstruum contains four grains: hence, while an ounce of the one may be employed for exciting full vomiting, the same quantity of the other would be too strong a dose. It is much to be regretted, that in articles of this active nature, the proportions employed by the two colleges should differ so considerably: that it would perhaps have been better, had the London college adopted the proportions employed by that of Edinburgh, as they have followed them in adopting this formula.

Wine of iron. L.

- 412 Take of filings of iron, four ounces; Spanish white wine, four pints. Digest for a month, often shaking the vessel and then strain.

This formula of the London pharmacopœia is now not only simplified, but improved, when compared with their former *vinum chalybatum*: for the cinnamon and other articles which were then conjoined with the iron, were certainly rather prejudicial than otherwise; but at the same time, rhenish wine, formerly employed, is perhaps to be considered as a better menstruum than the Spanish wine now directed. It may still, however, be justly considered as a good chalybeate; and we think the Edinburgh college have done wrong in rejecting the formula from their pharmacopœia.

By the London college it was formerly prepared by maceration, without heat; now, however, they direct digestion for the space of a month. Some have ob-

jected to the use of heat, that it impregnated the wine more strongly with the metal, and thus rendered it more unpleasant to the taste: but if this was the only inconvenience the remedy would be easy, diluting it with more wine. Heat has another effect, much less desirable, and which art cannot remedy: making a disagreeable alteration in the quality of the wine itself: hence it is necessary that it should be very moderate.

Steel wine is a very useful preparation of this metal, and frequently exhibited in chlorotic and other indispositions where chalybeates are proper. Boerhaave recommends it as one of the noblest medicines he was acquainted with for promoting that power in the body by which blood is made, when weakened by a bare debility of the over relaxed solids, and an indolent, cold, aqueous indisposition of the juices: for in this case, says he, no virtue of any vegetable or animal substance, no diet, nor regimen, can effect that which is effected by iron: but it proves hurtful where the vital powers are already too strong, whether this proceeds from the fluids or the solids. The dose is from a dram to half an ounce; which may be repeated two or three times a-day.

Some direct solutions of iron, made in wine or other vegetable acids, to be evaporated to the consistence of an extract, under the title of *extractum martis*. These preparations have no advantage, in point of virtue, above the common chalybeates: though in some forms, that of pills in particular, they may be rather more commodiously exhibited than most of the officinal chalybeates of equal efficacy. They may be made into pills by themselves, and are tenacious enough to reduce other substances into that form.

Wine of ipecacuanha. L.

- Take of the root of ipecacuanha, bruised, two ounces; Spanish white wine, two pints. Digest for ten days, and strain. 413

Wine, or tincture, of ipecacuanha. E.

Take of ipecacuanha, in powder, one ounce; Spanish white wine, fifteen ounces. After three days maceration, let the tincture be filtrated for use.

Both these wines are very mild and safe emetics, and equally serviceable in dysenteries also with the ipecacuanha in substance; this root yielding nearly all its virtues to the Spanish white wine here ordered, as it does a good share of them even to aqueous liquors. The common dose is an ounce, more or less, according to the age and strength of the patient. The college of Edinburgh added formerly a scruple of cochineal, which imparts a fine red colour to the liquor; this article is now omitted, on a complaint that the red colour of the matters evacuated sometimes alarmed the patient, as if it proceeded from a discharge of blood.

Wine of millepeds. E.

- Take of live millepeds, bruised, one ounce; Rhenish wine, eight ounces. Infuse them together for twelve hours, and afterwards press the liquor through a strainer. 414

This wine has been commended as an admirable cleanser of all the viscera, yielding to nothing in the jaundice and obstructions of the kidneys or urinary passages,

Preparations and Compositions.

passages, of excellent service in almost all chronic distempers, even in serofulous and stromous swellings, and in defluxions of rheum upon the eyes. But those who expected these extraordinary virtues from it have often been deceived; and at present there are few who have any great dependence on it; and hence it is omitted by the London college, probably without any loss. It is directed to be given from half an ounce to two ounces.

Wine of rhubarb. L.

- 415 Take of sliced rhubarb, two ounces and an half; lesser cardamom seeds, bruised and husked, half an ounce; saffron two drams; Spanish white wine, two pints; proof-spirit, eight ounces. Digest for ten days, and strain.

Rhubarb wine. E.

Take of rhubarb, two ounces: white canella, one dram; proof spirit, two ounces; Spanish white wine, fifteen ounces. Macerate for seven days, and strain.

By assisting the solvent power of the menstruum, the proof-spirit in the above formulæ is a very useful addition. This is a warm, cordial, laxative medicine. It is used chiefly in weakness of the stomach and bowels, and some kinds of loosenesses for evacuating the offending matter, and strengthening the tone of the viscera. It may be given from half a spoonful to three or four spoonfuls or more, according to the circumstances of the disorder, and the purposes it is intended to answer.

Tobacco-wine.

- 416 Take of the dried leaves of the best Virginian tobacco, one ounce; Spanish white wine, one pound. Macerate for four days, and then strain the liquor.

We have already, under the article NICOTIANA, offered some observations on its late introduction into practice by Dr Fowler, as a very useful remedy in the cure of dropsies and dysurics. From his treatise on that subject the present formula is taken; and we may observe, that while in practice we have frequently experienced from the tobacco those good effects for which Dr Fowler recommends it, we are inclined to give the present formula the preference to every other which he has proposed. It seems to extract more fully the active principles of the tobacco than either water or spirit taken separately. For further observations on the medical virtues of tobacco, see the article NICOTIANA.

Squill-wine. Succ.

- 417 Take of dried squills sliced, one ounce; ginger, one dram; French white wine, two pounds. Macerate for three days, and then strain.

By the wine employed as a menstruum, the active properties of the squills may be readily extracted; and in some cases at least the present formula may justly be considered as intitled to a preference over either the vinegar or oxymel of squills, which have a place in our pharmacopœias. The ginger here added to the squills operates as an useful corrigent; and on this account the present formula is preferable to the squill-wine of some other pharmacopœias, where the squills alone are used: For it is chiefly used in those cases where it is

intended that the squills should exert their effects, not on the alimentary canal, but on the kidneys or other excretories,

Zedoary wine. Dan.

Take of the root of zedoary, gently bruised, two pounds; spirit of wine, eight pounds. Let them be macerated for a month; then add spring water, eight pounds. Distil from thence twelve pounds.

Though this formula has the name of a wine, yet it is in reality a distilled spirit, nothing from the zedoary but a portion of its essential oil being united with the ardent spirit; and we are inclined to think, that the active powers of this article, both as depending on aroma and bitterness might be better obtained by a simple infusion in Spanish white wine.

CHAP. XXI. *Tinctures.*

RECTIFIED spirit of wine is the direct menstruum of the resins and essential oils of vegetables, and totally extracts these active principles from sundry vegetable matters, which yield them to water either not at all, or only in part. It dissolves likewise the sweet saccharine matter of vegetables; and generally those parts of animal-bodies in which their peculiar smell and taste reside.

The virtues of many vegetables are extracted almost equally by water and rectified spirit; but in the watery and spirituous tinctures of them there is this difference, that the active parts in the watery extraction, are blended with a large proportion of inert gummy matter, on which their solubility in this menstruum in a great measure depends, while rectified spirit extracts them almost pure from gum. Hence, when the spirituous tinctures are mixed with watery liquors, a part of what the spirit had taken up from the subject generally separates and subsides, on account of its having been freed from that matter which, being blended with it in the original vegetable, made it soluble in water. This, however, is not universal; for the active parts of some vegetables, when extracted by rectified spirit, are not precipitated by water, being almost equally soluble in both menstrua.

Rectified spirit may be tinged by vegetables of all colours except blue; the leaves of plants in general, which give out but little of their natural colour to watery liquors, communicate to spirit the whole of their green tincture, which for the most part proves elegant, though not very durable.

Fixed alkaline salts deepen the colour of spirituous tinctures; and hence they have been supposed to promote the dissolving power of the menstruum, though this does not appear from experience: in the trials that have been made to determine this affair, no more was found to be taken up in the deeper coloured tinctures than in the paler ones, and often not so much; if the alkali be added after the extraction of the tincture, it will heighten the colour as much as when mixed with the ingredients at first. Nor does the addition of these salts make tinctures useless only, but likewise prejudicial, as they in general injure the flavour of aromatics, and superadd a quality, sometimes contrary to the intention of the medicine. Volatile alkaline salts, in many cases, promote the action of the spirits. A-

cids generally weaken it; unless when the acid has been previously combined with the vinous spirit into a compound or new qualities, called *dulcified spirit*.

Tincture of wormwood. E.

- 420 Take of the flowering tops of wormwood, properly dried, four ounces; rectified spirit of wine, two pounds. Macerate for two days; then press out the spirit, and pour it on two ounces of wormwood. Macerate again for four days; then press the tincture through a cloth, and afterwards strain it through paper.

The aromatic parts of wormwood are more especially found in the flowering tops, and its bitterness in the leaves: but as the latter are replete with a mucilaginous matter, which might impede the action of the menstruum on the aromatic parts in this very elegant formula, the flowering tops are infused first, and their tincture made to extract the bitter parts of the leaves and stalks. This preparation may therefore be considered as containing the whole virtues of the plant.

In the tincture of wormwood we have one of the strongest of the vegetable bitters. It is sometimes used as an anthelmintic, and still more frequently in stomach ailments: But to most people it is a very disagreeable medicine.

Tincture of aloes. L.

- 421 Take of socotorine aloes, powdered, half an ounce; extract of liquorice, an ounce and an half; distilled water, proof-spirit, of each eight ounces. Digest in a sand bath, now and then shaking the vessel, until the extract be dissolved, and then strain.

In this simple tincture all the active parts of the aloes, whether of a gummy or resinous nature, are suspended in the menstruum. The extract of liquorice serves both to promote the suspension and to cover the taste of the aloes; and in these cases where we wish for the operation of the aloes alone, without the aid either of an adjuvans or corrigens, this is perhaps one of the best formulæ under which aloes can be exhibited in a fluid state.

Compound tincture of aloes. L.

- 422 Take of tincture of myrrh, two pints; saffron, socotorine aloes, of each three ounces. Digest for eight days, and strain.

Elixir of aloes, commonly called Elixir proprietatis, E.

Take of myrrh in powder, two ounces; socotorine aloes, an ounce and a half; English saffron, one ounce; rectified spirit of wine, proof-spirit, of each one pound. Digest the myrrh with the spirit for the space of four days; then add the aloes in powder, and the saffron; continue the digestion for two days longer, suffer the feces to subside, and pour off the clear elixir.

These two formulæ, though the mode of preparation be somewhat varied, do not materially differ from each other; and both may be considered as being the *elixir proprietatis* of Paracelsus, improved with regard to the manner of preparations. The myrrh, saffron, and aloes, have been usually directed to be digested in the spirit together: by this method, the menstruum soon

loads itself with the latter, so as scarcely to take up any of the myrrh; while a tincture, extracted first from the myrrh, readily dissolves a large quantity of the others. The alkaline salt, commonly ordered in these preparations with a view to promote the dissolution of the myrrh, we have already observed to be useless; and accordingly it is now omitted. Instead of employing the rectified spirit alone, the Edinburgh college have used an equal portion of proof-spirit, which is not only a more complete menstruum, but also renders the medicine less heating.

This medicine is highly recommended, and not undeservedly, as a warm stimulant and aperient. It strengthens the stomach and other viscera, cleanses the first passages from tenacious phlegm, and promotes the natural secretions in general. Its continued use has frequently done much service in cachectic and icteric cases, uterine obstructions, and other similar disorders; particularly in cold pale phlegmatic habits. Where the patient is of a hot bilious constitution and florid complexion, this warm stimulating medicine is less proper, and sometimes prejudicial. The dose may be from twenty drops to a tea spoonful or more, two or three times a-day, according to the purposes which it is intended to answer.

Vitriolic elixir of aloes or proprietatis. E.

- 423 Take of myrrh, socotorine aloes, each an ounce and a half; English saffron, one ounce; dulcified spirit of vitriol, one pound. Digest the myrrh with the spirit for four days in a close vessel; then add the saffron and aloes. Digest again four days; and when the feces have subsided, pour off the elixir.

The Edinburgh college have reformed this preparation considerably; and especially by directing the myrrh to be digested first, for the same reasons as were observed on the preceding article. Here the dulcified spirit of vitriol is very judiciously substituted for the spirit of sulphur, ordered in other books of pharmacy to be added to the foregoing preparation; for that strong acid precipitates from the liquor great part of what it had before taken up from the other ingredients; whereas, when the acid is previously combined with the vinous spirit, and thereby dulcified, as it is called, it does not impede its dissolving power. This elixir possesses the general virtues of the preceding, and is, in virtue of the menstruum, preferred to it in hot constitutions and weaknesses of the stomach.

Aromatic tincture. E.

- 424 Take of cinnamon, six drams; lesser cardamom seeds, one ounce; garden-angelica root, three drams; long pepper, two drams; proof-spirit, two pounds and an half. Macerate for seven days, and filter the tincture.

This preparation is improved from the preceding editions by the omission of some articles, either superfluous or foreign to the intention; galangal, gentian, zedoary, bay-berries, and calamus aromaticus. As now reformed, it is a sufficiently elegant warm aromatic.

This very warm aromatic is too hot to be given without dilution. A tea-spoonful or two may be taken in wine or any other convenient vehicle, in languors, weak-

Preparations and Compositions.

weakness of the stomach, flatulencies, and other similar complaints; and in these cases it is often employed with advantage.

Tincture of asafœtida. L.

- 425 Take of asafœtida, four ounces; rectified spirit of wine, two pints. Digest with a gentle heat for six days, and strain.

Fetid tincture. E.

Take of asafœtida, two ounces; vinous spirit of sal ammoniac one pound. Macerate for six days in a close shut vessel, and strain.

Of these two formulæ, the last is perhaps most generally useful: The vinous spirit of sal ammoniac is not only a more powerful menstruum than the rectified spirit of wine, but also coincides with the general virtues of the remedy.

This tincture possesses the virtues of the asafœtida itself; and may be given from ten drops to fifty or sixty. It was first proposed to be made with proof-spirit; this dissolves more of the asafœtida than a rectified one; but the tincture proves turbid; and therefore rectified spirit, which extracts a transparent one, is very justly preferred where ardent spirit is to be employed: and with this menstruum we can at least exhibit the asafœtida in a liquid form to a greater extent.

Tincture of balsam of Peru. L.

- 426 Take of balsam of Peru, four ounces; rectified spirit of wine, one pint. Digest until the balsam be dissolved.

The whole of the Peruvian balsam is dissolved by spirit of wine; this therefore may be considered as a good method of freeing it from its impurities; while at the same time it is thus reduced to a state under which it may be readily exhibited: but at present it is very little employed, unless in composition, either under this or any other form.

Tincture of balsam of Tolu.

- 427 Take of balsam of Tolu, one ounce and an half; rectified spirit of wine, one pint. Digest until the balsam be dissolved and strain. L.

Take of balsam of Tolu, an ounce and an half; rectified spirit of wine, one pound. Digest until the balsam be dissolved, and then strain the tincture. E.

This solution of balsam of Tolu possesses all the virtues of the balsam itself. It may be taken internally, with the several intentions for which that valuable balsam is proper, to the quantity of a tea-spoonful or two, in any convenient vehicle. Mixed with the plain syrup of sugar, it forms an elegant balsamic syrup.

Compound tincture of benzoin. L.

- 428 Take of benzoin, three ounces; storax strained, two ounces; balsam of Tolu one ounce; socotorine aloes, half an ounce; rectified spirit of wine, two pints. Digest with a gentle heat for three days, and strain.

Traumatic balsam. E.

Take of benzoin, three ounces; balsam of Peru, two ounces; hepatic aloes, half an ounce; rectified spi-

rit of wine, two pounds. Digest them in a sand heat for the space of ten days, and then strain the balsam.

Preparations and Compositions

Although the London college have changed the name of this composition, yet they have made very little alteration on the formula which, in their last edition, had the name of *Traumatic balsam*; a name which it still retains in the Edinburgh pharmacopœia; and both may be considered as elegant contractions of some very complicated compositions, which were celebrated under different names; such as Baume de Commandeur, Wade's balsam, Friar's balsam, Jesuit's drops, &c. These, in general, consisted of a confused farrago of discordant substances. They, however, derived considerable activity from the benzoin and aloes; and every thing to be expected from them may readily be obtained from the present formulæ.

The compound tincture of benzoin, or traumatic balsam, stands highly recommended, externally, for cleansing and healing wounds and ulcers, for discussing cold tumours, allaying gouty, rheumatic, and other old pains and aches; and likewise internally, for warming and strengthening the stomach and intestines, expelling flatulencies, and relieving colic complaints. Outwardly, it is applied cold on the part with a feather; inwardly, a few drops are taken at a time, in wine or any other convenient vehicle.

There is, however, reason to think that its virtues have been considerably over-rated; and at present it is much less employed than formerly, recourse being chiefly had to it in cases of recent wounds, with the view of stopping hæmorrhagies, and of promoting healing by the first intention, as it is called.

Tincture of the Spanish fly.

Take of bruised cantharides, two drams; cochineal, powdered, half a dram; proof-spirit one pint and an half. Digest for eight days and strain. L.

429

Take of cantharides, one dram; proof-spirit, one pound. Digest for four days, and strain through paper. E.

These tinctures possess the whole virtues of the fly, and are the only preparations of it designed for internal use: tinctures being by far the most commodious and safe form for the exhibition of this active drug. The two tinctures are scarcely different in virtue from each other. The cochineal is used only as a colouring ingredient: the gum-guaiacum, camphor, and essential oil of juniper-berries, which were formerly added, however well adapted to the intentions of cure, could be of little consequence in a medicine limited to so small a dose. If any additional substances should be thought requisite for promoting the effect of the cantharides, whether as a diuretic, as a detergent in ulcerations of the urinary passages, or as a specific refringent of seminal gleet and the fluor albus, they are more advantageously joined extemporaneously to the tincture, or interposed by themselves at proper intervals. The usual dose of these tinctures is from ten to twenty drops; which may be taken in a glass of water, or any other more agreeable liquor, twice a day; and increased by two or three drops at a time according to the effect.

The tincture of cantharides has of late been highly celebrated as a successful remedy in diabetic cases; and

Prepara-
tions and
Composi-
tions.

and in some instances of this kind, its use has been pushed to a very considerable extent, without giving rise to any stragurious affections: But we have not found it productive of a change for the better in any of those cases of diabetes in which we have tried it.

Tincture of cardamom.

- 430 Take of lesser cardamom seeds, husked and bruised, three ounces; proof spirit, two pints. Digest for eight days, and strain. *L.*

Take of lesser cardamom-seeds, six ounces proof-spirit, two pounds and a half. Macerate for eight days, and strain through paper. *E.*

Tincture of cardamom has been in use for a considerable time. It is a pleasant, warm cordial; and may be taken, along with any proper vehicle, from a dram to a spoonful or two.

Compound tincture of cardamom. *L.*

- 431 Take of lesser cardamom seeds, husked, carraway-seeds, cochineal, each, powdered, two drams; cinnamon, bruised, half an ounce; raisins, stoned, four ounces; proof-spirit, two pints. Digest for fourteen days, and strain.

This tincture contains so small a proportion of cardamoms as to be hardly intitled to derive its name from that article; and from the large proportion of raisins which it contains, the influence of the aromatics must be almost entirely prevented, while, at the same time, from these it cannot be supposed to obtain any active impregnation.

Tincture of cascarilla. *L.*

- 432 Take of the bark of cascarilla, powdered, four ounces; proof-spirit two pints. Digest with a gentle heat for eight days, and strain.

Proof spirit readily extracts the active powers of the cascarilla: and the tincture may be employed to answer most of these purposes for which the bark itself is recommended: But in the cure of intermittents, it in general requires to be exhibited in substance.

Tincture of castor.

- 433 Take of Russia castor, powdered, two ounces; proof-spirit, two pints. Digest for ten days, and strain. *L.*

Take of Russia castor, an ounce and a half; rectified spirit of wine, one pound; digest them with a gentle heat for six days, and afterwards strain off the liquor. *E.*

An alkaline salt was formerly added in this last prescription which is here judiciously rejected, as being at least an useless, if not a prejudicial, ingredient. It has been disputed whether a weak or rectified spirit, and whether cold or warm digestion, are preferable for making this tincture. To determine this point, the following experiment has been mentioned. "Some fine Siberia castor having been infused in good French brandy without heat, for twenty days, the tincture proved very weak: On the same individual castor (the magma or residuum of the former tincture) the same quantity of rectified spirit was poured as before of brandy; and after a few hours warm digestion, a tincture was extracted much stronger than the other." But this experiment is not satisfactory: the effects of

the two menstrua, and of heat, having been respectively compared in very different circumstances.

From other trials, it appears that castor, macerated without heat, gives out its finer and most grateful parts to either spirit, but most perfectly to the rectified. That heat enables both menstrua to extract greatest part of its grosser, and more nauseous matter; and proof-spirit extracts this last more readily than rectified.

The tincture of castor is recommended in most kinds of nervous complaints and hysterical disorders: In the latter it sometimes does service, though many have complained of its proving ineffectual. The dose is from twenty drops to forty, fifty, or more.

Compound tincture of castor. *E.*

- 434 Take of Russia castor one ounce; asafetida, half an ounce; vinous spirit of sal ammoniac one pound. Digest for six days in a close stopped phial, frequently shaking the vessel; and then strain the tincture.

This composition is a medicine of real efficacy, particularly in hysterical disorders, and the several symptoms which accompany them. The spirit here used is an excellent menstruum, both for the castor and the asafetida, and greatly adds to their virtues.

Tincture of catechu. *L.*

- 435 Take of catechu, three ounces; cinnamon, bruised, two ounces; proof-spirit, two pints. Digest for three days, and strain.

Japonic tincture. *E.*

- 436 Take of Japan earth, three ounces; cinnamon, two ounces; proof-spirit, two pounds and a half. After digestion for eight days, let the tincture be passed through a strainer.

A tincture of this kind, with the addition of Peruvian bark, ambergris, and musk, to the ingredients above directed, was formerly kept in the shops. The tincture here received is preferable for general use: where any other ingredients are required, tinctures of them may be occasionally mixed with this in extemporaneous prescription. The cinnamon is a very useful addition to the catechu, not only as it warms the stomach, &c. but likewise as it improves the roughness and astringency of the other.

The tincture is of service in all kinds of defluxions, catarrhs, loosenesses, uterine fluors, and other disorders, where mild astringent medicines are indicated. Two or three tea-spoonfuls may be taken every now and then in red wine or in any other proper vehicle.

Tincture of cinnamon.

- 437 Take of cinnamon, bruised one ounce and an half; proof-spirit, one pint. Digest for ten days, and strain. *L.*

- 438 Take of cinnamon, three ounces; proof-spirit, two pounds and a half. Macerate for eight days, and strain. *E.*

The tincture of cinnamon possesses the restringent virtues of the cinnamon, as well as all its aromatic cordial ones; and in this respect it differs from the distilled waters of that spice.

Compound

Prepara-
tions and
Composi-
tions.

Preparations and Compositions.

Compound tincture of Cinnamon. L.

437

Take of cinnamon, bruised, six drams; lesser cardamom-seeds, hufked, three drams; long pepper, ginger, of each, in powder, two drams; proof spirit, two pints. Digest for eight days and strain.

From the different articles which this tincture contains it must necessarily be of a more hot and fiery nature than the former, though much less strongly impregnated with the cinnamon.

Tincture of colomba. L.

438

Take of colomba-root, powdered two ounces and an half: proof spirit, two pints. Digest for eight days and strain.

The colomba readily yields its active qualities to the menstruum here employed: and accordingly, under this form, it may be advantageously employed against bilious vomitings, and those different stomach ailments, in which the colomba has been found useful; but where there does not occur some objection to its use in substance, that form is in general preferable to the tincture, which is now for the first time introduced into the London pharmacopœia.

Tincture of orange peel. L.

439

Take of the fresh exterior peel of Seville oranges, three ounces; proof spirit, two pints. Digest for three days, and strain.

By this menstruum, both the bitter quality of the orange skins, and likewise their peculiar essential oil, are extracted: hence it may be employed for any purpose in medicine which these are capable of answering. It is, however, but rarely used; and, as well as the former, has now only for the first time a place in the London pharmacopœia.

Tincture of Peruvian-bark.

440

Take of Peruvian bark, powdered four ounces; proof spirit, two pints. Digest with a gentle heat for eight days, and strain. L.

Take of Peruvian bark, four ounces; proof spirit, two pounds and a half. Digest for ten days, and strain. E.

A medicine of this kind has been for a long time pretty much in esteem, and usually kept in the shops, though but lately received into the pharmacopœias. Some have employed highly-rectified spirit of wine as a menstruum; which they have taken care fully to saturate, by digestion on a large quantity of the bark. Others have thought of assisting the action of the spirit by the addition of a little fixed alkaline salt, which does not however appear to be of any advantage; and others have given the preference to the vitriolic acid, which was supposed by giving a greater consistence to the spirit, to enable it to sustain more than it would be capable of doing by itself; at the same time that the acid improves the medicine by increasing the roughness of the bark. This last tincture, and that made with rectified spirit, have their advantages; though, for general use, that above directed is the most convenient of any, the proof spirit extracting nearly all the virtues of the bark. It may be given from a tea-spoonful to half an ounce, or an

ounce, according to the different purposes it is intended to answer.

Compound tincture of Peruvian bark. L.

Take of Peruvian bark, powdered, two ounces; exterior peel of Seville oranges, dried, one ounce and an half; Virginian snake-root, bruised, three drams; saffron, one dram; cochineal, powdered, two scruples; proof spirit, twenty ounces. Digest for fourteen days, and strain.

This has been for a considerable time celebrated under the title of *Husham's tincture of bark*.

The substances here joined to the bark, in some cases, promote its efficacy in the cure of intermittents, and not unfrequently are absolutely necessary. In some ill habits, particularly where the viscera and abdominal glands are obtruded, the bark, by itself, proves unsuccessful, if not injurious; while given in conjunction with stimulating stomachics and deobstruents, it more rarely fails of the due effect. Orange-peel and Virginian snake-root are among the best additions for this purpose; to which it is thought by some necessary to join chalybeate medicines also.

As a corroborant and stomachic, it is given in doses of two or three drams; but when employed for the cure of intermittents, it must be taken to a greater extent. For this purpose, however, it is rarely employed, unless with those who are averse to the use of the bark in substance, or whose stomachs will not retain it under that form.

Tincture of saffron. E.

Take of English saffron, one ounce; proof spirit, fifteen ounces. After digesting them for five days, let the tincture be strained through paper.

This tincture is similar in virtue to the saffron wine. A spirituous menstruum is here preferred to the wine as a tincture drawn with the former retains its elegant colour longer, and is not apt to deposit in keeping any part of what it had taken up from the saffron. The shops have been accustomed to employ treacle-water as a menstruum for saffron, with a view to the promoting its efficacy with the intention of operating as an alexipharmac; but the acid in that compound water soon destroys the colour of the tincture.

Tincture of muriatic iron. L.

Take of the rust of iron, half a pound; muriatic acid three pounds; rectified spirit of wine, three pints. Pour the muriatic acid on the rust of iron in a glass vessel; and shake the mixture now and then during three days. Set it by, that the feces may subside; then pour off the liquor; evaporate this to one pint, and, when cold, add to it the vinous spirit.

Tincture of iron. E.

Take of the scales of iron, purified and powdered, three ounces; muriatic acid, as much as is sufficient to dissolve the powder. Digest with a gentle heat; and the powder being dissolved, add of rectified spirit of wine as much as will make up of the whole liquor two pounds and a half.

Of these two formulæ, that of the Edinburgh college is, in our opinion, in several respects intitled to

Preparations and Compositions.

441

the preference. The scales are much fitter for giving a proper solution than the rust. The strength of the muriatic acid is so variable, that the quantity is left to the judgment of the operator. If the acid be superabundant, the solution is of a green colour; if it be fully saturated with the iron, it is more or less of a reddish or yellow colour; and this serves as a pretty accurate criterion. As the muriatic acid combines less intimately with rectified spirit than any of the fossil acids, so the after process of dulcification scarcely, if at all, impairs the solvent power of the acid; though, when the dulcification happens to be more than usually complete, a small quantity of ferruginous matter is sometimes precipitated on adding the rectified spirit to the solution. But as the rectified spirit increases the volatility of the acid, so if it was added at first, we should lose much more of the menstruum by the heat employed during the digestion. When this tincture is well prepared, it is of a yellowish-red colour; if the acid be superabundant, it is more or less of a greenish hue; and if the rectified spirit has been impregnated with the astringent matter of oak casks, it assumes an inky colour.

All the tinctures of iron are no other than real solutions of the metal made in acids, and combined with vinous spirits. The tinctures here directed differ from each other only in strength, the acid being the same in both. In our former pharmacopœias, there was a tincture from the matter which remains after the sublimation of the martial flowers; which, though it appears to be a good one, is now expunged as superfluous. Some have recommended dulcified spirit of nitre as a menstruum; but though this readily dissolves the metal, it does not keep it suspended. The marine is the only acid that can be employed for this purpose.

These tinctures are greatly preferable to the calces or croci of iron, as being not only more speedy, but likewise more certain in their operation. The latter, in some cases pass off through the intestinal tube with little effect; while the tinctures scarce ever fail. From ten to twenty drops of either of the tinctures may be taken two or three times a-day, in any proper vehicle; though it is seldom advisable to extend the dose of any tinctures of iron so far as the last of these quantities, especially with the tincture in spirit of salt, which is exceedingly strong of the iron.

Tincture of foot. E.

- 444 Take of shining wood-foot, one ounce; asafœtida, half an ounce; rectified spirit of wine, proof-spirit, of each half a pound. Digest for six days, and strain.

The proof-spirit is not liable to any objection here, as giving a turbid tincture; for when foot is added, whatever spirit be employed, the tincture will not prove transparent. Fuller, in his Pharmacopœia Domestica, has a medicine under the title of *hysteric tincture*, similar to this, only with a little myrrh, which is no very material addition to asafœtida and foot. These medicines are found serviceable, not only in hysterical cases, but likewise in other nervous disorders. They may be given from a tea-spoonful to a table-spoonful twice a-day.

This medicine has by some been thought serviceable

in obstructions of the menses; but its activity may be considered as depending much more on the asafœtida than on the foot.

Tincture of galbanum. L.

- Take of galbanum, cut into small pieces, two ounces; proof-spirit, two pints. Digest with a gentle heat for eight days, and strain. 445

This tincture is now for the first time introduced by the London college, and may be usefully employed for answering several purposes in medicine. Galbanum is one of the strongest of the fetid gums; and although less active, yet much less disagreeable than asafœtida: and under the form of tincture it may be successfully employed in cases of flatulence and hysteria, where its effects are immediately required, particularly with those who cannot bear asafœtida.

Compound tincture of gentian. L.

- Take of gentian root, sliced and bruised, two ounces; exterior dried peel of Seville oranges, one ounce; lesser cardamom seeds, husked and bruised, half an ounce; proof spirit, two pints. Digest for eight days, and strain. 446

Bitter tincture or stomachic elixir. E.

- Take of gentian-root, two ounces; Seville orange-peel, dried, one ounce; white canella, half an ounce; cochineal, half a dram; proof-spirit, two pounds and a half. Macerate for four days, and strain through paper.

These are very elegant spirituous bitters. As the preparations are designed for keeping, lemon-peel, an excellent ingredient in the watery bitter infusions, has, on account of the perishableness of its flavour, no place in these. The aromatics are here a very commodious ingredient, as in this spirituous menstruum they are free from the inconvenience with which they are attended in other liquors, of rendering them untransparent.

Elixir of guaiacum. E.

- Take of gum-guaiacum, one pound; balsam of Peru, three drams; rectified spirit of wine, two pounds and a half. Digest for ten days, and strain. 447

This tincture may be considered as nearly agreeing in medical virtues with the two following. It is, however, less in use; but it may be employed with advantage in those cases where an objection occurs to the menstruum used in forming the others.

Tincture of gum-guaiacum. L.

- Take of gum-guaiacum, four ounces; compound spirit of ammonia, a pint and a half. Digest for three days, and strain. 448

Volatile elixir of guaiacum. E.

- Take of gum-guaiacum, four ounces; balsam of Peru, two drams; distilled oil of saffras, half a dram; vinous spirit of sal ammoniac, a pound and an half. Macerate for six days in a close vessel, and strain.

In the last of these formulæ, the vinous spirit of sal ammoniac is less acrimonious than the menstruum directed by the London college; and the balsam of Peru, and distilled oil of saffras, are useful additions, by

Preparations and Compositions.

by increasing the permanence of its operation as a general stimulant, or more particularly as a diaphoretic.

These are very elegant and efficacious tinctures; the volatile spirit excellently dissolving the gum, and at the same time promoting its medicinal virtue. In rheumatic cases, a tea or even table spoonful, taken every morning and evening in any convenient vehicle, particularly in milk, has proved of singular service.

Tincture of black hellebore. L.

- 449 Take of black hellebore root, in coarse powder, four ounces; cochineal, powdered, two scruples; proof-spirit, two pints. Digest with a gentle heat for eight days, and strain.

Tincture of melampodium, or black hellebore. E.

Take of black hellebore root, four ounces; cochineal, half a dram; proof-spirit, two pounds and a half. Digest them together for eight days, and afterwards filter the tincture through paper.

This is perhaps the best preparation of hellebore when designed for an alterative, the menstruum here employed extracting the whole of its virtues. It has been found, from experience, particularly serviceable in uterine obstructions; in sanguine constitutions, where chalybeates are hurtful, it has been said that it seldom fails of exciting the menstrual evacuations, and removing the ill consequences of their suppression. So great, according to some, is the power of this medicine, that wherever, from an ill conformation of the parts, or other causes, the expected discharge does not succeed on the use of it, the blood, as Dr Mead has observed, is so forcibly propelled, as to make its way through other passages. A tea spoonful of the tincture may be taken twice in a day in warm water or any other convenient vehicle.

The college of Edinburgh had formerly a tincture of this root with wine. Proof spirit is undoubtedly preferable, both as a menstruum, and as being better fitted for keeping.

Tincture of jalap.

- 450 Take of powdered jalap root, eight ounces; proof-spirit, two pints. Digest with a gentle heat for eight days, and strain. *L.*

Take of jalap in coarse powder, three ounces; proof-spirit, fifteen ounces. Digest them for eight days, and strain the tincture. *E.*

Rectified spirit of wine was formerly ordered for the preparation of this tincture; but rectified spirit dissolving little more than the pure resinous parts of the jalap, rendered the use of the medicine somewhat less commodious than that of the tincture prepared with proof-spirit. Most of the tinctures made in rectified spirit, diluted with water, so as to be fit for taking, form a turbid white mixture. Many of them are safely taken in this form, without any further addition: but the cathartic ones are never to be ventured on without an admixture of syrup or mucilage to keep the resin united with the liquor; for if it separates in its pure undivided state, it never fails to produce violent gripes.

Vol. XIV.

Some have preferred to the tinctures of jalap, a Preparation dissolved in spirit of wine of a known quantity of the resin extracted from the root; and observe that this solution is more certain in strength than any tincture that can be drawn from the root directly. For, as the purgative virtue of jalap resides in its resin, and as all jalap appears from experiment not to be equally resinous some sorts yielding five, and others not three, ounces of resin from sixteen; it follows, that although the root be always taken in the same proportion to the menstruum, and the menstruum always exactly of the same strength, it may, nevertheless, according to the degree of goodness of the jalap, be impregnated with different quantities of resin, and consequently prove different in degree of efficacy. Though this objection against the tincture does not reach so far as some seem to suppose, it certainly behoves the apothecary to be careful in the choice of the root. The inferior sorts may be employed for making resin of jalap, which they yield in as great perfection, though not in so large quantity, as the best. Neumann thinks even the warm eaten jalap as good for that purpose as any other.

Tincture of gum kino. E.

- Take of gum kino, two ounces; proof spirit, a pound and an half. Digest eight days, and strain. 451

The substance called *gum-kino* seems to be really a gum resin; on which account proof-spirit is the most proper menstruum. This preparation must therefore possess the virtues of the substance; and it is perhaps one of the best forms under which it can be exhibited in obstinate diarrhoeas, and in cases of lenteria: but in hemorrhagies, it is in general proper to exhibit it either in substance or diffused; yet we cannot help thinking that the want of this tincture is an omission in the London pharmacopœia.

Compound tincture of lavender. L.

- Take of spirit of lavender, three pints; rosemary, one pint; cinnamon bruised, nutmegs bruised, of each half an ounce; red sanders, one ounce. Digest for ten days, and strain. 452

Compound spirit of lavender. E.

- Take of simple spirit of lavender three pounds; simple spirit of rosemary, one pound; cinnamon, one ounce; cloves, two drams; nutmeg, half an ounce; red sanders, three drams. Macerate seven days, and strain.

These two compositions, although varying a little from each other, both with respect to their ingredients and names, may yet be considered as precisely the same. Although the London college, in the present edition of their pharmacopœia, have made many useful alterations with respect to names, yet the propriety of the change here adopted may perhaps be doubted: For it cannot with justice be styled a tincture of lavender, when the distilled spirit of that plant is employed only as a menstruum. If, therefore, it seemed necessary to refer it to the head of tinctures, it ought to have been denominated from the cinnamon or nutmegs; but since the activity of this article very much depends on the spirit of lavender,

vender, the old name is in our opinion justly preferable to the new one.

The red Saunders is of no farther use in these compositions than as a colouring ingredient. If a yellow spirit was liked, the yellow Saunders would be an excellent article, as it not only communicates a fine colour, but likewise a considerable share of medicinal virtue. A spirit distilled from the flowers of lavender and sage, in due proportion, and digested in the cold for a little time with some cinnamon, nutmegs, and yellow Saunders, proves a very elegant and grateful one. Where essential oils are employed, particular care must be had in the choice of them; for on their goodness that of the medicine depends. The digestion of the spirit with the spices, &c. should be performed without heat, otherwise the flavour of the medicine will be injured. These spirits are grateful reviving cordials: though considerably more simple, they are not less elegant or valuable than many other more elaborate preparations. This medicine has long been held in great esteem, under the name of *Palsy drops* in all kinds of languors, weakness of the nerves, and decays of age. It may be conveniently taken on sugar, from ten to eighty or a hundred drops.

Tincture of musk. E.

453 Take of musk, two drams; rectified spirit of wine one pound. Digest for ten days, and strain.

Rectified spirit is the most complete menstruum for musk; but in this form it is often impossible to give such a quantity of musk as is necessary for our purpose; and hence this article is more frequently employed under the form of julep or bolus.

Tincture of myrrh.

454 Take of myrrh, bruised, three ounces; proof-spirit, a pint and an half; rectified spirit of wine, half a pint. Digest with a gentle heat for eight days, and strain. *L.*

Take of myrrh three ounces; proof-spirit two pounds and a half. After digestion for ten days strain off the tincture. *E.*

The pharmaceutical writers in general have been of opinion, that no good tincture can be drawn from myrrh by spirit of wine alone, without the assistance of fixed alkaline salts. But it appears from proper experiments, that these salts only heighten the colour of the tincture, without enabling the menstruum to dissolve any more than it would by itself. Rectified spirit extracts, without any addition, all that part of the myrrh in which its peculiar smell and taste reside, viz. the resin: and proof-spirit dissolves almost the whole of the drug, except its impurities; hence the combination of these two directed by the London college is perhaps preferable to either by itself.

Tinctures of myrrh is recommended internally for warming the habit, attenuating viscid juices, strengthening the solids, opening obstructions, particularly those of the uterine vessels, and resisting putrefaction. Boerhaave greatly esteems it in all languid cases proceeding from simple inactivity; in those female disorders which are occasioned by an aqueous, mucous, sluggish, indispotion of the humours, and a relaxation of the vessels; in the fluor albus, and all diseases aris-

ing from a like cause. The dose is from fifteen drops to forty or more. The medicine may doubtless be given in these cases to advantage; though with us, it is more commonly used externally for cleansing foul ulcers and promoting the exfoliation of carious bones.

Tincture of opium. L.

Take of hard purified opium, powdered, ten drams; proof-spirit, one pint. Digest for ten days, and strain.

455

Tincture of opium, commonly called liquid laudanum. E.

Take of opium, two ounces; spirituous cinnamon-water, one pound and a half. Digest four days, and strain off the tincture.

These are very elegant liquid opiates, the menstruum in the last dissolves nearly the whole substance of the opium, and effectually covers its ill flavour. It were to be wished that the shops were furnished with a liquid opiate, in which the proportion of menstruum was still much larger, so as to admit of the dose being determined by weight or measure; the method by drops seeming too precarious for a medicine of so powerful a kind. The following preparation is contrived with this view.

Take of thebaic extract, half a dram; highly rectified spirit of wine, called *alcohol*, ten ounces; simple cinnamon-water twenty ounces. Digest them together until the opium be dissolved, and then filter the solution through paper.

This preparation is apprehended to be free from all the inconveniences attending the common opiate tinctures. The menstruum dissolves the whole of the opium except the impurities, and consequently the tincture is not liable to any uncertainty in point of strength. The dose may be ascertained to the greatest exactness; one grain of opium is contained in one ounce by measure, which is equal nearly to seven drams by weight. Neither the tinctures in wine nor proof-spirit are so well adapted for keeping as could be wished: in long standing, a part of the opium is gradually thrown off from both, and consequently the tinctures become gradually weaker: the part which thus separates, amounts sometimes, it is said, to near one-fourth of the quantity of opium at first dissolved: it floats on the surface of the vinous tincture, and in the spirituous sinks to the bottom. In the preparation here recommended, it has not been observed that any separation happens.

Instead of the cinnamon water, pure water may be employed in the mixture; and where aromatic additions are wanted, either with a medicinal intention or for covering the ill smell of the opium, any proper tincture or distilled water may be extemporaneously joined. Saffron, an addition once employed by the Edinburgh college, has been considered as a corrector of opium; but the qualities it was supposed to correct are merely imaginary; nor indeed can that article be of much importance with any intention in the small quantity that enters a dose of the tincture; a grain of opium being accompanied with only half a grain of saffron.

A preparation in some respects similar to that here recommended was introduced into the Edinburgh phar-

Preparations and Compositions.

pharmacopœia published in 1774, under the title of *tinctura meconii*. Each ounce of this tincture contained four grains of opium; and it was proposed that the doses of it should be measured, not by drops, but by weight: but as modern physicians are much more bold in giving opium than their predecessors, such a scrupulous accuracy in the dose is not thought at all necessary; and it is not probable that any dangerous consequence will ever arise, merely from a difference in the size of drops. This, however, might be the case, where the thebaic tincture is by accident taken for the tincture of meconium. To such mistakes, however, it was feared that the analogy of the articles, as well as the caution necessary with respect to both, might lead; and it was on many accounts safer to have but one liquid laudanum only. It is, however, much to be regretted, that the liquid laudanum of the London and Edinburgh college, which by the former is now styled *tinctura opii*, by the latter *tinctura thebaica*, should differ so much from each other in point of strength.

Camphorated tincture of opium. L.

456 Take of hard purified opium, flowers of benzoin, each one dram; camphor, two scruples: essential oil of aniseed one dram; proof-spirit, two pints. Digest for three days.

Purgative elixir. E.

Take of flowers of benzoin, English saffron, each three drams; opium, two drams; essential oil of aniseeds, half a dram; vinous spirit of sal ammoniac, sixteen ounces. Digest for four days in a close vessel and strain.

These too, though differing not merely in name, may be considered as agreeing very nearly in their nature.

The most material differences in the last formula from the first are the substitution of the vinous spirit of sal ammoniac for the proof-spirit, and a larger proportion of opium; the vinous spirit of sal ammoniac is not only perhaps, a more powerful menstruum, but in most instances coincides with the virtues of the preparation; but as the opium is the ingredient on which we place the principal dependence, so its proportion is increased, in order that we may give it in such a dose as that the acrimony of the menstruum shall not prove hurtful to the stomach.

The London formula is taken from Le Mort, with the omission of three unnecessary ingredients, honey, liquorice, and alkaline salt. It was originally called *elixir asthmaticum*, which name it does not ill deserve. It contributes to allay the tickling which provokes frequent coughing; and at the same time is supposed to open the breast, and give greater liberty of breathing: the opium procures (as it does by itself) a temporary relief from the symptoms; while the other ingredients tend to remove the cause, and prevent their return. It is given to children against the chincough, &c. from five drops to twenty: to adults, from twenty to an hundred. In the London formula, half an ounce by measure contains about a grain of opium; but in the Edinburgh formula the proportion of opium is larger.

Tincture of rhubarb.

Take of rhubarb, sliced, two ounces; lesser cardamom seeds, hulled and bruised, half an ounce; saffron, two drams; proof-spirit, two pints. Digest for eight days and strain. L.

Take of rhubarb, three ounces; lesser cardamom seeds, half an ounce: proof-spirit two pounds and a half. Digest for seven days, and strain. E.

Compound tincture of rhubarb. L.

Take of rhubarb sliced, two ounces; ginger powdered, saffron, each two drams; liquorice root, bruised; half an ounce; distilled water, one pint; proof-spirit twelve ounces. Digest for fourteen days, and strain.

Bitter tincture of rhubarb. E.

Take of rhubarb two ounces; gentian-root, half an ounce; Virginian snake-root, one dram; proof-spirit, two pounds and a half. Digest for seven days, and then strain the tincture.

Sweet tincture of rhubarb. E.

It is made by adding to two pounds and a half of the strained tincture of rhubarb, four ounces of fig-candy.

The last of these preparations is improved from the former editions. Two ounces of liquorice and one of raisins are supplied, by an increase of the fig-candy.

All the foregoing tinctures of rhubarb are designed as stomachics and corroborants, as well as purgatives; spirituous liquors excellently extract those parts of the rhubarb in which the two first qualities reside, and the additional ingredients considerably promote their efficacy. In weakness of the stomach, indigestion, flatulency of the intestines, diarrhœas, colic, and other similar complaints, these medicines are frequently of great service: the second is also in many cases, an useful addition to the Peruvian bark, in the cure of intermittents, particularly in cachectic habits, where the viscera are obstructed; with these intentions, a spoonful or two may be taken for a dose, and occasionally repeated.

Elixir of aloes and rhubarb, commonly called *sacred elixir.* E.

Take of rhubarb, cut small, ten drams: soccorine aloes, in powder, six drams; lesser cardamom seeds, half an ounce; proof-spirit, two pounds and a half. Digest for seven days, and then strain the elixir.

This preparation is very much employed as a warming cordial purge, and for the general purposes of aloetics; with which, however, it combines the medicinal properties of rhubarb.

Compound tincture of savin. L.

Take extract of savin, one ounce; tincture of castor, one pint; myrrh, half a pint. Digest till the extract of savin be dissolved, and then strain.

This preparation had a place in the last edition of our pharmacopœia, under the title of *Elixir myrrhe compositum*.

Preparations and Compositions.

457

This preparation is improved from one described in some former dispensaries under the name of *uterine elixir*. It is a medicine of great importance in uterine obstructions, and in hypochondriacal cases; though, possibly, means might be contrived of superadding more effectually the virtues of lavin to a tincture of myrrh and castor. It may be given from five drops to twenty or thirty, or more, in pennyroyal water, or any other suitable vehicle.

Tincture of squill. L.

460 Take of squills, fresh dried, four ounces; proof-spirit, two pints. Digest for eight days, and pour off the liquor.

For extracting the virtues of squills, the menstruum which has hitherto been almost solely employed is vinegar. There are however, cases in which ardent spirit may be more proper; and by the menstruum here directed its virtues are fully extracted. Hence it is with propriety that the London college have introduced this form, as well as the vinegar and oxymel. But, in general, the purposes to be answered by squills may be better obtained by employing it in substance than in any other form.

Antiphthysical tincture. E.

461 Take of sugar of lead an ounce and a half; vitriol of iron, one ounce; rectified spirit of wine, one pound. Let a tincture be extracted without heat.

The reducing of the salts *separately* into powder, and performing the digestion *without heat*, are very necessary circumstances: for if the ingredients be attempted to be pulverized together, they will grow soft and almost liquid; and if heat be used, scarce any tincture will be obtained.

This tincture is sometimes given in doses of twenty or thirty drops for restraining immoderate secretions, particularly the colligative sweats attending hectic fevers and phthisical disorders; whence the name *antiphthysical tincture*. It is undoubtedly a medicine of great efficacy in these cases, but too dangerous to be rashly ventured on. Some have supposed that it does not contain any of the sugar of lead; but experiments made for that purpose have shown the contrary.

We must however, consider the above preparation as unscientific. Both the acetous and vitriolic acid have a greater attraction for iron than for lead: and though the vitriolic be capable of discharging the acetous acid, yet it makes not only in its entire state a less perfect union with lead than the acetous acid, but it is now also combined with iron, for which it has a greater attraction, and can therefore only act on the salt of lead in proportion as it is superabundant in the salt of copperas; but in proportion as the vitriolic disengages the acetous acid from the lead, the last, in its turn will attach itself to the iron. On the whole it is difficult to ascertain the precise nature of this preparation; it seems always, however, to contain a quantity of lead in a saline state, sufficient to expunge it from prudent practice: or, at least, if in these cases in which it has hitherto been employed, lead be thought necessary, the salt of lead may with more safety and advantage be given in its solid state, particularly when combined with opium: and it is probably on this ac-

count that the present formula has now no place in the London pharmacopœia.

Tincture of fenna. L.

462 Take of fenna, one pound; caraway-seeds, bruised, one ounce and an half; lesser cardamom-seeds, hulled and bruised, half an ounce; raisins, stoned, sixteen ounces; proof-spirit, one gallon. Digest for fourteen days, and strain.

Compound tincture of fenna, commonly called Elixir of h. alb. E.

Take of fenna leaves, two ounces; jalap root, one ounce; coriander seeds, half an ounce; proof spirit, two pounds; and a half. Digest for seven days, and to the strained liquor add four ounces of sugarcandy.

Both these tinctures are useful carminatives and cathartics, especially to those who have accustomed themselves to the use of spirituous liquors; they oftentimes relieve flatulent complaints and colics, where the common cordials have little effect; the dose is from one to two ounces. Several preparations of this kind have been offered to the public under the name of *Duffy's elixir*: the two above are equal to any, and superior to most of them. The last in particular is a very useful addition to the castor oil, in order to take off its mawkish taste: and as coinciding with the virtues of the oil, it is therefore much preferable to brandy, shrub, and such like liquors, which otherwise are often found necessary to make the oil fit on the stomach.

Tincture of snake root.

463 Take of Virginian snake-root, three ounces; proof-spirit, two pints. Digest for eight days, and strain. L. Take of Virginian snake-root, two ounces; cochineal, one dram; proof spirit, two pounds and a half. Digest in a gentle heat for four days, and then strain the tincture. E.

The tincture of snake-root was in a former pharmacopœia directed to be prepared with the tincture of salt or tartar, which being now expunged, it was proposed to the college to employ rectified spirit; but as the heat of this spirit prevents the medicine from being taken in so large a dose as it might otherwise be, a weaker spirit was chosen. The tincture made in this menstruum, which extracts the whole virtues of the root, may be taken to the quantity of a spoonful or more every five or six hours; and to this extent it often operates as an useful diaphoretic.

Tincture of valerian. L.

464 Take of the root of wild valerian, in coarse powder, four ounces; proof-spirit, two pints. Digest with a gentle heat eight days, and strain.

The valerian root ought to be reduced to a pretty fine powder, otherwise the spirit will not sufficiently extract its virtues. The tincture proves of a deep colour, and considerably strong of the valerian; though it has not been found to answer so well in the cure of epileptic disorders as the root in substance, exhibited in the form of powder, or bolus. The dose of the tincture is from half a spoonful to a spoonful or more two or three times a-day.

Prepara-
tions and
Composi-
tions*Volatile tincture of Valerian.*

Take of the root of wild valerian, four ounces; compound spirit of ammonia, two pints. Digest for eight days, and strain. *L.*

465

Take of wild valerian root two ounces; vinous spirit of sal ammoniac, one pound. Macerate for six days in a close vessel and strain. *E.*

Both the compound and vinous spirit of sal ammoniac are here excellent menstua, and at the same time considerably promote the virtues of the valerian, which in some cases wants an assistance of this kind. The dose may be a tea spoonful or two.

Tincture of veratrum, or white hellebore.

466

Take of white hellebore root, eight ounces; proof-spirit, two pounds and a half. Digest them together for ten days, and filter the tincture through paper.

This tincture is sometimes used for acuating cathartics, &c. and as an emetic in apoplectic and maniacal disorders. It may likewise be so managed as to prove a powerful alterative and deobstruent in cases where milder remedies have little effect. But a great deal of caution is requisite in its use: the dose at first ought to be only a few drops; if considerable, it proves, violently emetic or cathartic.

Acid elixir of vitriol. E.

467

Take of rectified spirit of wine, two pounds; drop into it by little and little six ounces of vitriolic acid; Digest the mixture with a very gentle heat in a close vessel for three days, and then add of cinnamon, an ounce and a half; ginger, one ounce. Digest again in a close vessel for six days, and then filter the tincture through paper placed in a glass funnel.

The intention in this process is, to obtain a tincture of aromatic vegetables, in spirit of wine, combined with a considerable proportion of vitriolic acid. When the tincture is first drawn with vinous spirit, and the acid added afterwards, the acid precipitates great part of what the spirit had before taken up: and on the other hand, when the acid is mixed with the spirit immediately before the extraction, it prevents the dissolution of all that it would have precipitated by the former way of treatment: by previously uniting the acid and the vinous spirit together by digestion, the inconvenience is somewhat lessened.

This is a valuable medicine in weakness and relaxations of the stomach and decays of constitution, particularly in those which proceed from irregularities, which are accompanied with slow febrile symptoms, or which follow the suppression of intermittents. It frequently succeeds after bitters and aromatics by themselves had availed nothing; and indeed great part of its virtues depend on the vitriolic acid; which, barely diluted with water, has, in those cases where the stomach could bear the acidity, produced happy effects.

Fuller relates (in his *Medicina Gymnastica*) that he was recovered by Mynsicht's elixir, from an extreme decay of constitution, and continual retchings to vomit. It may be given from 10 to 30 or 40 drops or more, according to the quantity of acid, twice or thrice a-day, at such times as the stomach is most

empty. It is very usefully conjoined with the Bark, both as covering its disagreeable taste and coinciding with its virtues.

Prepara-
tions and
Composi-
tions,*Sweet elixir of vitriol. E.*

This is made of the same aromatics, and in the same manner as the aromatic tincture; except that, in place of the vinous, the dulcified spirit of vitriol is employed.

468

This is designed for persons whose stomachs are too weak to bear the foregoing acid elixir; to the taste, it is gratefully aromatic, without any perceptible acidity. The dulcified spirit of vitriol, here directed, occasions little or no precipitation on adding it to the tincture.

A medicine of this kind was formerly in great esteem under the title of *Vigani's volatile elixir of vitriol*; the composition of which was first communicated to the public in the *Pharmaceutia reformata*. It is prepared by digesting some volatile spirits of vitriol upon a small quantity of mint leaves curiously dried, till the liquor has acquired a fine green colour. If the spirit, as it frequently does, partakes too much of the acid, this colour will not succeed: in such case it should be rectified from a little fixed alkaline salt.

Camphorated spirit of wine. E.

Take of camphor, one ounce; rectified spirit of wine, one pound. Mix them together, that the camphor may be dissolved. It may also be made with a double, triple, &c. proportion of camphor.

469

This solution of camphor is employed chiefly for external uses, against rheumatic pains, paralytic numbnesses, inflammations, for dissolving tumours, preventing gangrenes, or restraining their progress. It is too pungent to be exhibited internally, even when diluted, nor does the dilution succeed well; for on the admixture of aqueous liquors, the camphor gradually separates and runs together into little masses.

Hoffman, Rothen, and others, mention a camphorated spirit not subject to this inconvenience. It is prepared by grinding the camphor with somewhat more than an equal weight of fixed alkaline salt, then adding a proper quantity of proof-spirit, and drawing off one half of it by distillation. This spirit was proposed to be received into our pharmacopœias, under the title of *Spiritus camphoræ tartarizatus*. But on trial it did not answer expectation: some of the camphor rises with the spirit in distillation, though but a small quantity; whence, mixed with a large portion of water, it does not sensibly render it turbid; but in a proper quantity, it exhibits the same appearance as the more common camphorated spirit: it did not appear, that spirit distilled from camphor, with or without the alkaline salt, differed at all in this respect.

The most convenient method of uniting camphor with aqueous liquors, for internal use, seems to be by the mediation of almonds, or of mucilages; triturated with these, it readily mingles with water into the form of an emulsion, at the same time that its pungency is considerably abated. It may also be commodiously exhibited in the form of an oily draught, expressed oils totally dissolving it.

The anodyne liniment, commonly called Anodyne balsam. E.

Take of opium, an ounce; white Castile soap, four ounces;

ounces; camphor, two ounces; essential oil of rosemary, half an ounce; rectified spirit of wine, two pounds. Digest the opium and soap in the spirit for three days; then to the strained liquor add the camphor and oil, diligently shaking the vessel.

The several ingredients in this formula are exceedingly well suited for the purposes expressed in the title of this preparation; the anodyne balsam has accordingly been used with much success to allay pains in strained limbs, and such like topical affections.

Saponaceous balsam or liniment. E.

- 471 This is made in the same manner and of the same ingredients as the anodyne balsam, only omitting the opium.

It is intended as a simplification and improvement of what had formerly the name of *Opodellock*, and is employed with the same intentions as the two preceding.

Tincture of antimony. Ross.

- 472 Take of antimony, in powder, half a pound; salt of tartar, one pound; rectified spirit, three pints. Mix the antimony with the salt of tartar, and inject them by little and little into a crucible placed in a strong fire. Let the mixture melt thin, and continue in this state for half an hour; after which it is to be poured out into a hot and dry iron mortar. Powder the mass while hot, put into it a heated matras, and pour the spirit on it. Digest them together for three days, and then strain the tincture.

In this process the alkaline salt unites with the sulphur of the antimony into a hepar; which communicates to the spirit a tincture similar to the tincture of sulphur. This antimonial tincture is supposed to contain likewise some of the reguline parts of the mineral, and is said to have sometimes provoked a puke when taken on an empty stomach, even in a small dose. It stands recommended in doses from ten to sixty drops or more, as a deobstruent, promoter of urine, and purifier of the blood. But there is probably no purpose to be answered by it, which may not be more effectually obtained by other antimonial preparations, particularly the wine of tartar of antimony.

Tincture of colocynth. Succ.

- 473 Take of colocynth, cut small, and freed from the seeds, one ounce; anniseed, one dram; proof spirit, fourteen ounces. Macerate for three days, and strain through paper.

In this tincture we have the active purgative power of the colocynth. And although it be seldom used as a cathartic by itself, yet even in small quantity it may be advantageously employed to promote the operation of others.

Volatile tincture of copper. Gen.

- 474 Take of filings of copper, one dram; spirit of sal ammoniac, an ounce and a half. Mix them, and keep them in a vessel closely stopped, which is to be frequently agitated, till the liquor becomes of a beautiful violet colour.

In this formula the copper is brought to a saline state by means of the volatile alkali. It may therefore be considered as very analogous to the ammoniacal copper. And where recourse is had to it in practice, it is employed with the same intentions.

Tincture of quassa. Succ.

- Take of quassa, bruised, two ounces; proof-spirit, two pounds and an half. Digest for three days, and then strain through paper. 475

By proof-spirit the medical properties, as well as the sensible qualities of the quassa are readily extracted. And under this form it may be advantageously employed for answering different purposes in medicine.

Tincture of lac. Succ.

- Take of gum lac, powdered, one ounce; myrrh, three drams; spirit of scurvy-grass, a pint and an half. Digest in a sand heat for three days; after which, strain off the tincture for use. 476

This tincture is principally employed for strengthening the gums, and in bleedings and scorbutic exulcerations of them: it may be fitted for use with these intentions, by mixing it with honey of roses or the like. Some recommend it internally against scorbutic complaints, and as a corroborant in gleet, female weaknesses, &c. Its warmth, pungency, and manifestly astringent bitterish taste, point out its virtues in these cases to be considerable, though common practice among us has not yet received it.

Tincture of nux vomica. Ross.

- Take of nux vomica, an ounce and a half; proof-spirit, two pounds. Digest for some days, and then strain it. 477

The nux vomica, a very active vegetable, has of late as we have already had occasion to observe, been introduced into practice as taken internally, for the cure of intermittents and of contagious dysentery. In these affections it may be employed under the form of tincture as well as in substance; and in this way it most readily admits of being combined with other articles, either as adjuvantia or corrigentia.

Tincture of amber. Succ.

- Take of yellow amber, powdered, one ounce; vitriolic æther, four ounces. Digest for three days in a vessel accurately closed, frequently shaking the vessel, and after this strain through paper. 478

The tincture of amber was formerly prepared with rectified spirit of wine: but the menstruum here directed gives a more complete solution, and forms a more elegant and active tincture. It possesses the whole virtues of the concrete; and although it has no place in our pharmacopœia, yet it is perhaps to be considered as one of the most valuable preparations of amber. It has been recommended in a variety of affections, particularly those of the nervous kind, as hysterical and epileptic complaints. It may be taken from a few drops to the extent of a tea-spoonful in a glass of wine or any similar vehicle.

CHAP. XXII. *Mistures.**Camphorated mixture. L.*

- 479 TAKE of camphor, one dram; rectified spirit of wine, ten drops; double-refined sugar, half an ounce; boiling distilled water, one pint. Rub the camphor first with the spirit of wine, then with the sugar; lastly, add the water by degrees, and strain the mixture.

While camphor is often exhibited in a solid state, it is frequently also advantageous to employ it as diffused in watery fluids. And with this intention the present formula is perhaps one of the most simple, the union being effected merely by the aid of a small quantity of spirit of wine and a little sugar. But perhaps the more common form of emulsion in which the union is effected, by triturating the camphor with a few almonds, is not to be considered as inferior to this. For the unctuous quality of the almonds serves in a considerable degree to cover the pungency of the camphor without diminishing its activity. Camphor under the present form as well as that of emulsion, is very often useful in fevers, taken to the extent of a table spoonful every three or four hours.

Chalk mixture. L.

- 480 Take of prepared chalk, one ounce; double-refined sugar, six drams; gum-arabic, powdered, two ounces; distilled water, two pints. Mix them.

Chalk drink. E.

Take of prepared chalk, one ounce; purest refined sugar, half an ounce; mucilage of gum-arabic, two ounces. Rub them together, and add by degrees, water, two pounds and an half; spirituous cinnamon water, two ounces.

These two preparations agree pretty much both in their name and in their nature. But of the two formulae that of the Edinburgh college is most agreeable to the palate, from containing a proportion of cinnamon water, by which the disagreeable taste of the chalk is taken off.

In the former edition of the Edinburgh pharmacopœia, a preparation of this kind stood among the decoctions, and the chalk was directed to be boiled with the water and gum: by the present formula, the chalk is much more completely suspended by the mucilage and sugar; which last gives also to the mixture an agreeable taste. It is proper to employ the finest sugar, as the redundant acid in the coarser kinds might form with the chalk a kind of earthy salt. It would perhaps have been more proper to have added an aromatic, by suspending the entire powder of cinnamon, or its oil, by means of the mucilage and sugar: The method here directed is, however, less exceptionable in this than many other preparations, as the precipitated matter of the spirituous water will probably be inviscated in the saccharine and mucilaginous matter. This is a very elegant form of exhibiting chalk, and is an useful remedy in diseases arising from, or accompanied with, acidity in the primæ viæ. It is frequently employed in diarrhœa proceeding from that cause. The

mucilage not only serves to keep the chalk uniformly diffused, but also improves its virtues by sheathing the internal surface of the intestines. The dose of this medicine requires no nicety. It may be taken to the extent of a pound or two in the course of a day.

Preparations and Compositions.

Musk mixture. L.

- Take of musk, two scruples; gum-arabic, powdered, double refined sugar, of each one dram; rose-water, six ounces by measure. Rub the musk first with the sugar, then with the gum, and add the rose-water by degrees.

481

This had formerly the name of *julepum e moscho*, and was intended as an improvement upon the hysterical julep with musk of Bates. Orange-flower water is directed by that author; and indeed this more perfectly coincides with the musk than rose-water: but as the former is difficultly procurable in perfection, the latter is here preferred. The julep appears turbid at first: on standing a little time it deposits a brown powder, and becomes clear, but at the same time loses great part of its virtue. This inconvenience may be prevented by thoroughly grinding the musk with gum-arabic before the addition of the water; by means of the musk, the whole substance of the gum is made to remain suspended in the water. Volatile spirits are in many cases an useful addition to musk, and likewise enable water to keep somewhat more of the musk dissolved than it would otherwise retain.

Almond milk. L.

- Take of sweet almonds, one ounce and an half; double-refined sugar, half an ounce; distilled water, two pints. Beat the almonds with the sugar; then, rubbing them together, add by degrees the water, and strain the liquor.

482

Common emulsion. E.

- Take of sweet almonds, one ounce; bitter almonds, one dram; common-water, two pounds and a half. Beat the blanched almonds in a stone mortar, and gradually pour on them the common water, working the whole well together, then strain off the liquor.

Arabic emulsion. E.

- This is made in the same manner as the preceding; only adding, while beating the almonds, of mucilage of gum-arabic, two ounces.

483

All these may be considered as possessing nearly the same qualities. But of the three the last is the most powerful demulcent.

Great care should be taken, that the almonds be not become rancid by keeping; which will not only render the emulsion extremely unpleasant, a circumstance of great consequence in a medicine that requires to be taken in large quantities, but likewise give it injurious qualities little expected from preparations of this class. The addition of the bitter almonds now ordered by the Edinburgh college in preparing these emulsions, may perhaps preserve them in some degree from suffering the above changes; but is much more useful as giving the emulsion an agreeable flavour. And although the substance of bitter almonds be of a deleterious

rious

Prepara-
tions and
Composi-
tions.

rious nature, yet nothing is to be apprehended from the quantity here employed.

These liquors are principally used for diluting and obtunding acrimonious humours; particularly in heat of urine and stranguries arising either from a natural sharpness of the juices, or from the operation of cathartics and other irritating medicines: in these cases, they are to be drank frequently, to the quantity of half a pint or more at a time.

Some have ordered emulsions to be boiled, with a view to deprive them of some imaginary crudity; but by this process they quickly cease to be emulsions, the oil separating from the water, and floating distinctly on the surface. Acids and vinous spirits produce a like decomposition. On standing also for some days, without addition, the oily matter separates and rises to the top, not in a pure form, but like thick cream. These experiments prove the composition of the emulsions made from the oily seeds of kernels, and at the same time point out some cautions to be attended to in their preparation and use.

Ammoniacum milk. L.

484 Take of ammoniacum, two drams; distilled water, half a pint. Rub the gum-resin with the water, gradually poured on, until it becomes a milk. In the same manner may be made a milk of asafœtida, and of the rest of the gum-resins.

The ammoniacum milk is used for attenuating tough phlegm, and promoting expectoration, in humoral asthmas, coughs, and obstructions of the viscera. It may be given to the quantity of two spoonfuls twice a day.

The lac asafœtida is employed in spasmodical, hysterical, and other nervous affections. And it is also not unfrequently used under the form of injection. It answers the same purposes as asafœtida in substance.

Compound spirit of vitriolic æther. L.

485 Take of spirit of vitriolic æther, two pounds; oil of wine, three drams. Mix them.

This is supposed to be, if not precisely the same, at least very nearly, the celebrated mineral anodyne liquor of Hoffman; as we learn from his own writings, that the liquor which he thus denominated was formed of dulcified spirit of vitriol and the aromatic oil which arises after it, but he does not tell us in what proportions these were combined. It has been highly extolled as an anodyne and antispasmodic medicine; and with these intentions it is not unfrequently employed in practice.

Compound spirit of ammonia. L.

486 Take of spirit of ammonia, two pints; essential oil of lemon, nutmeg, of each two drams. Mix them.

This differs almost only in name from the following.

Volatile aromatic spirit, commonly called volatile oily spirit, and saline aromatic spirit. E.

Take of vinous spirit of sal ammoniac, eight ounces; distilled oil of rosemary, one dram and a half; distilled oil of lemon-peel, one dram. Mix them that the oils may be dissolved.

By the method here directed, the oils are as completely dissolved as when distillation is employed.

Volatile salts, thus united with aromatics, are not only more agreeable in flavour, but likewise more acceptable to the stomach, and less acrimonious than in their pure state. Both the foregoing compositions turn out excellent ones, provided the oils are good, and the distillation skilfully performed. The dose is from five or six drops to sixty or more.

Medicines of this kind might be prepared extemporaneously, by dropping any proper essential oil into the dulcified spirit of sal ammoniac, which will readily dissolve the oil without the assistance of distillation. But it is perhaps preferable that they should be kept in the shops ready mixed.

Succinated spirit of ammonia. L.

Take of alcohol, one ounce; water of pure ammonia, four ounces by measure; rectified oil of amber, one scruple; soap, ten grains. Digest the soap and oil of amber in the alcohol till they be dissolved; then add the water of pure ammonia, and mix them by shaking.

This composition is extremely penetrating, and has lately come into esteem, particularly for smelling to in lownesses and faintings, under the name of *eau de luce*. It has been hitherto brought from France. It is not quite limpid, for the oil of amber dissolves only imperfectly in the spirit: if the volatile spirit be not exceedingly strong, scarcely any of the oil will be imbibed.

The *eau de luce* is not only used with the view of making an impression on the nose, but is taken internally in the same cases. It has likewise of late been celebrated as a remedy for the bite of the rattlesnake, when used internally, and applied externally to the wounded part.

Camphorated spirit. L.

Take of camphor, four ounces; rectified spirit of wine, two pints. Mix them, so that the camphor may be dissolved.

Of this we have already had occasion to speak in the preceding chapter under the title given to it by the Edinburgh college.

Simple oily emulsion. Gen.

Take of almond oil, one ounce; syrup of althea, an ounce and a half; gum arabic, half an ounce; spring-water, six ounces. Mix, and make an emulsion according to art.

Volatile oily emulsion. Gen.

Take of almond oil, an ounce and a half; syrup of althea one ounce; gum arabic, half an ounce; volatile alkaline salt, one dram; spring water seven ounces. Mix them according to art.

Both these are elegant and convenient modes of exhibiting oil internally. And under these forms it is often advantageously employed in cases of cough, hoarseness, and similar affections. By means of the alkali, a more intimate union of oil with water is obtained than can be had with the intermedium either of syrup or vegetable mucilage; and in some cases, the

482

489

Preparations and Compositions.

the alkali both contributes to answer the intention in view, and prevents the oil from exciting sickness at stomach: But in other instances, the pungency which it imparts is disagreeable to the patient and unfavourable to the disease. According to these circumstances, therefore, where an oily mixture is to be employed, the practitioner will be determined in his choice to have recourse either to the one or the other formula.

Acid jul'p. Gen.

- 490 Take of weak vitriolic acid, three drams; simple syrup, three ounces; spring water, two pounds. Mix them.

In this state the vitriolic acid is sufficiently diluted to be taken with ease in considerable doses. And it may thus be advantageously employed in various affections; concerning which we have already had occasion to make a few remarks in CHEMISTRY, n^o 617. (see CHEMISTRY-Index), and which are to be answered, either by its action on the stomach, or on the system in general.

Æther jul'p. Gen.

- 491 Take of pure vitriolic æther, two scruples; spring-water, six ounces; refined sugar, half an ounce. Mix them according to art.

Although it is in general proper that æther should be diluted only when it is to be immediately used, yet it is sometimes necessary that it should be put into the hands of the patient in the state in which it is to be taken. In such instances the present formula is a very proper one; for the addition of a little mucilage tends both to cover the pungency of the æther in the mouth, and to retain it in a state of mixture with the water.

Amber jul'p. Gen.

- 492 Take of tincture of amber, two drams; refined sugar half an ounce; spring-water, six ounces. Mix them according to art.

Under this form the tincture of amber is so far diluted and sweetened, as to form an agreeable mixture; and in this manner it may often be advantageously employed for counteracting nervous affections, and answering those other purposes for which we have already mentioned that this article is had recourse to in practice.

Saline mixture, or jul'p. Succ.

- 493 Take of fixed vegetable alkali, three drams; river-water, half a pound. To this lixivium add, lemon-juice half a pound, or as much as is sufficient to saturate the alkali; syrup of black currants, one ounce.

This mixture is frequently prescribed in febrile diseases as a means of promoting a slight discharge by the surface: For where the skin is parched with great increased heat, it generally operates as a gentle diaphoretic. It often also promotes a discharge by the kidneys, and is not unfrequently employed to restrain vomiting. With these intentions it is in daily use among British practitioners, although it has no place in our pharmacopœias, from its being entirely an extemporaneous prescription.

Mineral solution of arsenic.

Preparations and Compositions.

494

Take of white arsenic, reduced to a subtile powder, fixed vegetable alkali, each sixty-four grains; distilled water, half a pint. Put them into a florentine flask, and let this be placed in a sand heat, so that the water may boil gently till the arsenic be completely dissolved; then add to the solution when cold half an ounce of spirit of lavender, and as much distilled water as to make the solution amount to a pint by measure, or fifteen ounces and an half by weight.

For the introduction of this remedy we are indebted to Dr Fowler of Stafford. We have already had occasion to mention it in our article ARSENIC, n^o 14; see also CHEMISTRY, n^o 1266, &c. In the former of these places we have observed, that if it be not precisely the same, it is at least supposed to be very analogous to a remedy which has had a very extensive sale in some parts of England under the name of the *tasteless ague drop*; and which has been employed with very great success in the cure of obstinate intermittents. But whether the present formula, in any degree approaches to the tasteless ague drop or not, there can be no doubt from the concurring testimony of many eminent practitioners, that it is equally successful in combating intermittents. For this purpose it is given according to the age and other circumstances of the patient in doses from two to twenty drops, once, twice, or oftener in the course of the day: And its use has been found to be attended with remarkable success, although with some patients even very small doses have been found to excite severe vomiting. Besides distinctly marked intermittents, this solution has also been sometimes successful in obstinate periodical headaches, and in cutaneous affections of the leprosy kind, resisting every other mode of cure. And perhaps in every case where arsenic can be employed with safety or advantage internally, this preparation is preferable to any other with which we are yet acquainted.

CHAP. XXIII. *Syrups.*

495 SYRUPS are saturated solutions of sugar, made in water, or watery or vinous infusions, or in juices. They were formerly considered as medicines of much greater importance than they are thought to be at present. Syrups and distilled waters were for some ages used as the great alteratives; inasmuch that the evacuation of any peccant humour was never attempted till by a due course of these it had first been supposed to be regularly prepared for expulsion. Hence arose the exuberant collection of both, which we meet with in pharmacopœias, and like errors have prevailed in each. As multitudes of distilled waters have been compounded from materials unfit to give any virtue over the helm; so numbers of syrups have been prepared from ingredients, which in this form cannot be taken in sufficient doses to exert their virtues: for two-thirds of a syrup consist of sugar, and greatest part of the remaining third is an aqueous fluid.

Syrups are at present chiefly regarded as convenient vehicles for medicines of greater efficacy; and used

for sweetening draughts and juleps; for reducing the lighter powders into baluses, pills, or electuaries, and other similar purposes. Some likewise may not improperly be considered as medicines themselves; as those of saffron, blackthorn berries, and some others.

To the chapter on *Syrups* the London college in their pharmacopœia have premised the following general observations.

In the making of syrups, where we have not directed either the weight of the sugar, or the manner in which it should be dissolved, this is to be the rule:

Take of double refined sugar, twenty-nine ounces; any kind of liquor, one pint. Dissolve the sugar in the liquor in a water-bath; then set it aside for twenty-four hours; take off the foam, and pour off the syrup from the feces if there be any.

The following are the general rules which have commonly been given with respect to the preparation of syrups.

I. All the rules laid down for making decoctions are likewise to be observed in the decoctions for syrups. Vegetables, both the decoctions and infusions, ought to be dry, unless they are expressly ordered otherwise.

II. In both the London and Edinburgh pharmacopœias, only the purest or double refined sugar is allowed.

In the syrups prepared by boiling, it has been customary to perform the clarification with whites of eggs after the sugar had been dissolved in this decoction of the vegetable. This method is apparently injurious to the preparation; since not only the impurities of the sugar are thus discharged, but a considerable part likewise of the medicinal matter, which the water had before taken up from the ingredients, is separated along with them. Nor indeed is the clarification and despumation of the sugar, by itself, very advisable; for its purification by this process is not so perfect as might be expected; after it has undergone this process, the refiners still separate from it a quantity of oily matter, which is disagreeable to weak stomachs. It appears, therefore, most eligible to employ fine sugar for all the syrups; even the purgative ones (which have been usually made with coarse sugar, as somewhat coinciding with their intention) not excepted; for, as purgative medicines are in general ungrateful to the stomach, it is certainly improper to employ an addition which increases their offensiveness.

III. Where the weight of the sugar is not expressed, twenty nine ounces are to be taken in every pint of liquor. The sugar is to be reduced into powder, and dissolved in the liquor by the heat of a water-bath, unless ordered otherwise.

Although in the formula of several of the syrups, a double weight of sugar to that of the liquor is directed, yet less will generally be sufficient. First, therefore, dissolve in the liquor an equal weight of sugar, then gradually add some more in powder, till a little remains undissolved at the bottom, which is to be afterwards incorporated by setting the syrup in a water bath.

The quantity of sugar should be as much as the liquor is capable of keeping dissolved in the cold: if there is more, a part of it will separate, and congregate into crystals or candy; if less, the syrup will be sub-

ject to ferment, especially in warm weather, and change into a vinous or sour liquor. If in crystallizing, only the superfluous sugar be separated, it would be of no inconvenience; but when a part of the sugar has candied the remaining syrup is found to have an under proportion, and is as subject to fermentation as if it had wanted sugar at first.

IV. Copper vessel, unless they be well tinned, should not be employed in the making of acid syrups, or such as are composed of the juices of fruits.

The confectioners, who are the most dexterous people at these kinds of preparations, to avoid the expense of frequently new tinning their vessels, rarely make use of any other than copper ones, untinned, in the preparation even of the most acid syrups, as of oranges and lemons. Nevertheless, by taking due care that their coppers be well scoured and perfectly clean, and that the syrup remain no longer in them than is absolutely necessary, they avoid giving it any ill taste or quality from the metal. This practice, however, is by no means to be recommended to the apothecary.

V. The syrup, when made, is to be set by till next day: if any saccharine crust appears upon the surface it is to be taken off.

Syrup of vinegar. E.

Take of vinegar, two pounds and an half; refined sugar, three pounds and an half. Boil them till a syrup be formed.

This is to be considered as simple syrup merely acidulated, and is by no means unpleasent. It is often employed in mucilaginous mixtures and the like; and on account of its cheapness it is often preferred to syrup of lemons.

Syrup of marshmallows.

Take of fresh root of marshmallow, bruised one pound; double-refined sugar, four pounds; distilled water, one gallon. Boil the water with the marshmallow root to one half, and press out the liquor when cold. Set it by twelve hours; and, after the feces have subsided, pour off the liquor. Add the sugar, and boil it to the weight of six pounds. L.

Take of marshmallow roots, somewhat dried, nine ounces; water ten pounds purest sugar, four pounds. Boil the water with the roots, to the consumption of one half, and strain the liquor, strongly expressing it. Suffer the strained liquor to rest till the feces have subsided; and when it is free from the dregs, add the sugar; then boil so as to make a syrup. E.

The syrup of marshmallows seems to have been a sort of favourite among dispensatory writers, who have taken great pains to alter and amend it, but have been wonderfully tender in retrenching any of its articles. In the last prescription, it is lopt of its superfluities, without any injury to its virtues. It is used chiefly in nephritic cases, for sweetening emollient decoctions, and the like: of itself it can do little service, notwithstanding the high opinion which some have entertained of it; for what can be expected from two or three spoonfuls of the syrup, when the decoction, from which two or three pounds are made, may be taken at a draught or two? It is sometimes useful in tickling coughs;

Preparations and Compositions.

coughs, by inviscating irritating matter distilling in the fueses: in this way it sometimes affords a considerable relief.

Syrup of clove July flowers.

498 Take of fresh clove July-flowers, the heels being cut off, two pounds; boiling distilled water, six pints. Macerate the flowers for twelve hours in a glass vessel; and in the strained liquor dissolve the double-refined sugar, that it may be made a syrup. *L.*

Take of clove July-flowers, fresh gathered and freed from the heels, one pound; purest sugar, seven pounds and a quarter; boiling water four pounds. Macerate the flowers in the water for a night; then to the strained liquor add the sugar previously beat, and dissolve it by a gentle heat, to make the whole into a syrup. *E.*

This syrup is of an agreeable flavour, and a fine red colour: and for these it is chiefly valued. Some have substituted for it one easily preparable at seasons when the flowers are not to be procured: an ounce of clove spice is infused for some days in twelve ounces of white wine, the liquor strained, and with the addition of twenty ounces of sugar, boiled to a proper consistence; a little cochineal renders the colour of this syrup exactly similar to that prepared from the clove July-flower; and its flavour is of the same kind, though not so pleasant. The abuse may be readily detected by adding to a little of the syrup some alkaline salt or ley; which will change the genuine syrup to a green colour; but in the counterfeit, it will make no such alteration, only varying the shade of the red.

As the beauty of the colour is a principal quality in this syrup, no force in the way of expression should be used in separating the liquor from the flowers.

Syrup of colchicum. E.

499 Take of colchicum root, fresh and succulent, cut into small pieces, one ounce; vinegar, sixteen ounces; purest sugar, twenty-six ounces. Macerate the root in the vinegar two days, now and then shaking the vessel: then strain it with a gentle pressure. To the strained liquor add the sugar, and boil a little, so as to form a syrup.

This syrup seems to be the best preparation of the colchicum; great care is required to take up this root in the proper season: and from errors of this kind we are to ascribe the uncertainty in the effects of this medicine as found in the shops.

The syrup of colchicum is often successfully employed as a diuretic, and may be taken from a dram or two to the extent of an ounce or more.

Syrup of orange peel.

500 Take of fresh outer-rind of Seville-oranges, eight ounces; boiling distilled water, five pints. Macerate for twelve hours in a close vessel; and in the strained liquor dissolve double-refined sugar to make a syrup. *L.*

Take of yellow rind of Seville orange-peel fresh, six ounces; boiling water, three pounds. Infuse them for a night in a close vessel; then strain the liquor; let it stand to settle; and having poured it off clear from the sediment, dissolve in it four pounds and a

quarter of white sugar, so as to make it into a syrup with a gentle heat. *L.*

In making this syrup, it is particularly necessary that the sugar be previously powdered, and dissolved in the infusion with as gentle a heat as possible, to prevent the exhalation of the volatile part of the peel. With these cautions, the syrup proves a very elegant and agreeable one, possessing great share of the fine flavour of the orange-peel.

Syrup of Saffron. L.

Take of saffron, one ounce; boiling distilled water, one pint. Macerate the saffron, in the water, for twelve hours, in a close vessel; and dissolve double-refined sugar in the strained liquor, that it may be made a syrup.

Saffron is very well fitted for making a syrup, as in this form a sufficient dose of it is contained in a reasonable compass. This syrup is at present frequently prescribed; it is a pleasant cordial, and gives a fine colour to juleps.

Syrup of lemon juice.

Take of lemon juice, strained, after the feces have subsided, two pints; double-refined sugar, fifty ounces.

Dissolve the sugar, that it may be made a syrup. *L.*
Take of juice of lemons, suffered to stand till the feces have subsided, and afterwards strained, two pounds and a half; double-refined sugar, fifty ounces. Dissolve the sugar in the juice, so as to make a syrup *E.*

*Syrup of mulberry-juice. L.**Syrup of raspberry-juice. L.**Syrup of black currants. L.*

These three are directed by the London college to be prepared in the same manner as syrup of lemons, which immediately precedes them.

All these four are very pleasant cooling syrups; and with this intention they are occasionally used in draughts and juleps, for quenching thirst, abating heat &c. in bilious or inflammatory distempers. They are sometimes likewise employed in gargarisms for inflammations of the mouth, and tonsils.

Syrup of the white poppy. L.

Take of the heads of white poppies, dried, and the seeds taken out, three pounds and an half; double-refined sugar, six pounds; distilled water, eight gallons. Slice and bruise the heads, then boil them in the water, to three gallons, in a water-bath saturated with sea-salt, and press out the liquor. Reduce this by boiling to about the measure of four pints, and strain it while hot, first through a sieve, then through a thin woollen cloth, and let it aside for twelve hours, that the feces may subside. Boil the liquor, poured off from the feces, to three pints, and dissolve the sugar in it that it may be made a syrup.

Syrup of white poppies, or of meconium, commonly called diacodium. E.

Take of white poppy heads, dried and freed from the seeds,

Preparations and Compositions.

feeds, two pounds; boiling water thirty pounds; purest sugar, four pounds. Macerate the bruised heads in the water for a night; next boil till only one-third part of the liquor remain; then strain it, expelling it strongly. Boil the strained liquor to the consumption of one half, and strain again; lastly, add the sugar, and boil to a syrup. It may also be made by dissolving in two pounds and a half of simple syrup, one dram of the extract of white poppies.

This syrup, impregnated with the opiate matter of the poppy heads, is given to children in doses of two or three drams; to adults from half an ounce to an ounce and upwards, for easing pain, procuring rest, and answering the other intentions of mild opiates. Particular care is requisite in its preparation, that it may be always made, as nearly as possible, of the same strength; and accordingly the colleges have been very minute in their description of the process.

Syrup of the red poppy. L.

504 Take of the fresh flowers of the wild or red poppy, four pounds; boiling distilled water, four pints and an half. Put the flowers by degrees into the boiling water in a water-bath, constantly stirring them. After this, the vessel being taken out of the bath, macerate for twelve hours; then press out the liquor, and set it apart, that the feces may subside. Lastly, make it into a syrup, with double-refined sugar.

The design of putting the flowers into boiling water in a water bath, is, that they may be a little scalded, so as to shrink enough to be all immersed in the water; without this artifice they can scarcely be all got in: but they are no longer to be continued over the fire than till this effect is produced, lest the liquor become too thick, and the syrup be rendered ropy.

This syrup has been recommended in disorders of the breast, cough, spitting of blood, pleurifies, and other diseases, both as an emollient and as an opiate. It is one of the lightest of the opiate medicines; and in this respect so weak, that some have doubted of its having any anodyne quality. We indeed presume, that it might be very safely superseded altogether; and accordingly it has now no place either in the Edinburgh pharmacopœia, or some of the best foreign ones, though still retained by the London college.

Rose-syrup. L.

305 Take of the dried leaves of the damask rose, seven ounces; double-refined sugar, six pounds; boiling distilled water, four pints. Macerate the rose leaves in water for twelve hours, and strain. Evaporate the strained liquor to two pints and an half, and add the sugar, that it may be made a syrup.

Syrup of pale roses. E.

Take of pale roses, fresh gathered, one pound; boiling water, four pounds; white sugar, three pounds. Macerate the roses in the water for a night; then to the liquor strained, and freed from the dregs, add the sugar; and boil them into a syrup.

This syrup may likewise be made from the liquor remaining after the distillation of rose water depurated from its feces.

The liquor remaining after the distillation of roses (provided the still has been perfectly clean) is as proper for making this syrup as a fresh infusion; for the distillation only collects those volatile parts which are dissipated in the air while the infusion is boiling to its consistence. This syrup is agreeable and mild purgative for children, in the dose of half a spoonful or a spoonful. It likewise proves gently laxative to adults; and with this intention may be of service in costive habits. Its principal use is in solutive glysters.

Syrup of dry roses. E.

Take of red roses, dried, seven ounces; white sugar, six pounds; boiling water, five pounds. Infuse the roses in the water for a night, then boil them a little; strain out the liquor, and adding to it the sugar, boil them to the consistence of a syrup.

This syrup is supposed to be mildly astringent; but is principally valued on account of its red colour. The London college have omitted it, having retained others at least equal to it in that respect.

Syrup of squills. E.

Take of vinegar of squills, two pounds; white sugar, three pounds and a half. Make them into a syrup with a gentle heat.

This syrup was formerly prepared with some spices, intended to alleviate the offensiveness of the squills. But while they had not this effect, they often counteracted the intention in view, and are therefore omitted. It is used chiefly in doses of a spoonful or two, for promoting expectoration, which it does very powerfully.

Simple or common syrup. E.

Take of purest sugar, fifteen parts; water, eight parts. Let the sugar be dissolved by a gentle heat.

This preparation is a plain liquid sweet, void of flavour or colour. It is convenient for sundry purposes where these qualities are not wanted, or would be exceptionable.

Syrup of buckthorn.

Take of the juice of ripe and fresh buckthorn berries, one gallon; ginger, bruised, one ounce; all-spice, powdered, one ounce and a half; double-refined sugar, seven pounds. Set by the juice for some days, that the feces may subside, and strain. Macerate the ginger and all-spice in a pint of the strained juice for four hours, and strain. Boil away the rest of the juice to three pints; then add that part of the juice in which the ginger and all-spice have been macerated; and, lastly, the sugar, that it may be made a syrup. L.

Take of the juice of the ripe buckthorn berries, depurated, seven pounds and an half; white sugar, three pounds and a half. Boil them to the consistence of a syrup. E.

Both these preparations, in doses of three or four spoonfuls, operate as brisk cathartics. The principal inconveniences attending them are, their being very unpleasant, and their occasioning a thirst and dryness of the mouth and fauces, and sometimes violent gripes. These effects may be prevented by drinking freely of

water.

Preparations and Compositions,

water gruel, or other warm liquids during the operation. The ungratefulness of the buckthorn is endeavoured to be remedied in the first of the above prescriptions by the addition of aromatics, which, however, are scarcely sufficient for that purpose. The second also had formerly an aromatic material for the same intention, a dram of the essential oil of cloves; which being found ineffectual, is now rejected.

Syrup of balsam of Tolu. L.

510 Take of the balsam of Tolu, eight ounces; distilled water, three pints. Boil for two hours. Mix with the liquor, strained after it is cold, the double refined sugar that it may be made a syrup,

Balsamic syrup. E.

Take of simple syrup, just made, and warm from the fire two pounds; tincture of balsam of Tolu, one ounce. When the syrup has grown almost cold, stir into it the tincture, by little at a time, agitating them well together till perfectly united.

This last method of making the balsamic syrup was dropt in one of the preceding editions of the Edinburgh pharmacopœia, on a complaint that the spirit spoiled the taste of the syrup: which it did in a great degree when the tincture was drawn with malt spirits, the nauseous oil which all the common malt spirits are accompanied with communicating that quality; and this was particularly the case when the spirituous part was evaporated from the syrup, as was directed in the former edition of the Edinburgh pharmacopœia. Particular care therefore should be taken that the spirit employed for making the tincture be perfectly clean, and well rectified from all ill flavour.

The intention of the contrivers of the two foregoing processes seems to have been somewhat different. In the first, the more subtle and fragrant parts of the balsam are extracted from the grosser resinous matter, and alone retained in the syrup: the other syrup contains the whole substance of the balsam in larger quantity. They are both moderately impregnated with the agreeable flavour of the balsam.

In some pharmacopœias a syrup of this kind is prepared from a tincture of balsam of Peru, with rose-water, and a proper quantity of sugar.

Syrup of violets.

511 Take of the fresh petals of the violet, two pounds; boiling distilled water, five pints. Macerate for 24 hours; afterwards strain the liquor, without pressing, through thin linen. Add refined sugar, that it may be made a syrup. *L.*

Take of fresh violets, one pound; boiling water four pounds; purest sugar, seven pounds and a half. Macerate the violets in the water for 24 hours in a glass, or at least a glazed earthen vessel, close covered; then strain without expression, and to the strained liquor add the sugar powdered, and make into a syrup. *E.*

This syrup is of a very agreeable flavour; and in the quantity of a spoonful or two proves to children gently laxative. It is apt to lose, in keeping, the elegant blue colour, for which it is chiefly valued; and

hence some having been induced to counterfeit it with materials whose colour is more permanent. This adulteration may be readily discovered, by adding to a little of the suspected syrup any acid or alkaline liquor. If the syrup be genuine, the acid will change its blue colour to a red, and the alkali will change it to a green; but if counterfeit, these changes will not happen. It is obvious, from this mutability of the colour of the violet, that the prescriber would be deceived if he should expect to give any blue tinge to acidulated or alkalinized juices or mixtures by the addition of the blue syrup.

Syrup of ginger.

Take of ginger bruised, four ounces; boiling distilled water, three pints. Macerate for four hours, and strain, then add refined sugar, that it may be made a syrup. *L.*

Take of powdered ginger, three ounces; boiling water, four pounds; purest sugar, seven pounds and a half. Macerate the ginger in the water in a close vessel for 24 hours; then to the liquor, strained and freed from the feces, add the powdered sugar, and make them into a syrup. *E.*

These are agreeable and moderately aromatic syrups, lightly impregnated with the flavour and virtues of the ginger.

Acid syrup. Gen.

Take of weak spirit of vitriol, two drams; syrup of lemons, six ounces. mix them.

Where we wish to obtain a syrup, not only strongly acidulated, but also powerfully astringent, this formula may be considered as well suited to answer the purpose.

Alkaline syrup. Gen.

Take of salt of tartar, three drams; simple syrup, six ounces. Mix them.

In this syrup we have in some degree the converse of the preceding; and it may be usefully employed either for the destruction of acid in the stomach, or for the formation of neutral or effervescent mixtures.

Syrup of garlic. Succ.

Take of the fresh root of garlic, sliced, one pound; boiling water, two pounds. Macerate them in a close vessel for an hour. Add to the strained liquor, refined sugar, two pounds.

This syrup formerly held a place in our pharmacopœias, and was recommended for promoting expectoration in cases of chronic catarrh and other affections of the breast: but, as well as the oxymel of garlic, it is now banished from them; and there can be little doubt that the same intentions may in general be answered by less disagreeable medicines. Yet where we wish to employ garlic in a watery menstruum, this formula is perhaps one of the best under which it can be exhibited.

Syrup of almonds. Succ.

Take of sweet almonds, one pound; bitter almonds, two drams. Let the almonds be blanched and beat in a stone mortar with a wooden pestle; then by degrees add barley-water, two pounds; strain the liquor,

Preparations and Complications.

It may, and form it into a Syrup, with as much double-refined sugar as may be necessary.

The agreeable Scent of the almonds in this formula communicated to a Syrup, which may be advantageously employed to sweeten mixtures, or to form a pleasurable drink when dissolved in water; and the flavour is not a little improved by the addition of the proportion of bitter almond here Directed. But even these cannot be supposed to communicate any active quality to this Syrup, as they are employed in so small a quantity: and still less is to be expected from the sweet almonds, which can communicate little more to the Syrup than their mild Oil.

Syrup of cinnamon. Ross.

- 517 Take of cinnamon, bruised, five ounces; spirituous cinnamon water, two pints. Digest them in a close glass vessel for 24 hours; then add to the strained liquor double refined sugar, three pounds. Boiled to a Syrup.

This Syrup is strongly impregnated with the cinnamon: and when we wish to sweeten any mixture, at the same time adding to it an agreeable aromatic, it is perhaps one of the best articles we can employ.

Emetic Syrup. Brun.

- 518 Take of glass of antimony, finely powdered, two drams; Rhenish wine, twelve ounces. Let them be digested for three days in a gentle heat; then strain the liquor through paper, and mix with the strained liquor 30 ounces of double-refined sugar. Let it be formed into a Syrup, and kept in a close vessel.

There can be no doubt of this Syrup being strongly impregnated with the emetic quality of the antimony; and it will at least have so far the advantage of being very agreeable to the taste, that it may be readily taken by very young people. But every good effect to be obtained from it may be had with more certainty, by adding to simple Syrup any quantity that may be thought necessary of the antimonial tartar previously dissolved in a small proportion of water.

Syrup of quicksilver. Succ.

- 519 Take of purified quicksilver, one dram; gum arabic, three drams; rose water, as much as sufficient for reducing the gum to mucus. Let them be rubbed in a mortar till the quicksilver totally disappears; then by degrees mix with it simple Syrup, four ounces.

In this we have a preparation similar to the mercurial solution of Dr Plenck formerly mentioned; and which, while it does not possess any other advantage than mere sweetness of taste, is liable to the objections formerly urged against that preparation.

CHAP. XXIV. *Medicinal Honies.*

- 520 THE more fixed parts of vegetables, dissolved in watery liquors may be thence transferred into honey by mixing the honey with the watery decoction or juice of the plant, and boiling them together till the aqueous part has exhaled, and the honey remains of its original consistence. Honey has not probably

however, any very peculiar advantage over sugar, and it is liable to many inconveniences which sugar is free from: in particular, it is much more liable to run into fermentation, and in many constitutions produces gripes, and often violent effects. The Edinburgh college have therefore rejected the whole of the oxymels from their last edition of the pharmacopœia. And the number of preparations with honey in most of the foreign pharmacopœias is now much diminished. Still, however, there are several much employed by practitioners of emiaence; and of course retained in the London pharmacopœia.

Honey of roses. L.

Take of dried red rose-buds, with the heels cut off, four ounces; boiling distilled water, three pints; clarified honey, five pounds. Macerate the rose leaves in the water for six hours; then mix the honey with the strained liquor, and boil the mixture to the thickness of a Syrup.

This preparation is not unfrequently used as a mild cooling detergent, particularly in gargarisms for ulcerations and inflammation of the mouth and tonsils. The rose buds here used should be hastily dried: the design of doing so is, that they may the better preserve their astringency.

Honey of squills. L.

Take of clarified honey, three pounds; tincture of squills, two pints. Boil them in a glass vessel to the thickness of a Syrup.

The honey will here be impregnated with all the active parts of the squills which the tincture before contained, and may be employed as an useful expectorant or diuretic.

Oxymel of verdigrise. L.

Take of prepared verdigrise, one ounce; vinegar, seven ounces; clarified honey, fourteen ounces. Dissolve the verdigrise in the vinegar, and strain it through linen; then add the honey, and boil the whole to a proper thickness.

This is an improvement of what was formerly known in our pharmacopœias under the title of *mel Ægyptiacum*; which, however, was, as then prepared, very uncertain with respect to strength. It is used only externally for cleansing foul ulcers; and keeping down fungous flesh. It is also often serviceable in venereal ulcerations of the mouth and tonsils. But there is some danger from its application to places from the situation of which it is apt to be swallowed; for even a small quantity of verdigrise passing into the stomach may be productive of distressing, if not deleterious, effects.

Oxymel of meadow saffron. L.

Take of the fresh root of meadow-saffron, cut into thin slices, one ounce; distilled vinegar, one pint; clarified honey, two pounds. Macerate the root of meadow-saffron with the vinegar, in a glass vessel, with a gentle heat, for 48 hours. Strain the liquor, pressed out strongly from the root, and add the honey. Lastly, boil the mixture, frequently stirring it with a wooden spoon, to the thickness of a Syrup.

This

Preparations and Complications.

Preparations and Compositions.

This oxymel may be considered as very analogous to the syrup of colchicum, on which we have already made some observations. Under this form it was first introduced by Dr Stoerk. And although with certain constitutions the syrup is unquestionably preferable, yet it well deserves a place in our pharmacopœias, as being an active medicine.

Oxymel of squills. L.

525 Take of clarified honey, three pounds; vinegar of squills, two pints. Boil them in a glass vessel, with a slow fire, to the thickness of a syrup.

The honey was formerly employed for this preparation unclarified, and the scum, which in such cases arises in the boiling, taken off: by this means the impurities of the honey were discharged; but some of the medicinal parts of the squills, with which the vinegar was impregnated, were also separated. For this reason the college of London have now judiciously ordered the honey for all these kinds of preparations to be previously clarified by itself.

Oxymel of squills is an useful aperient, detergent, and expectorant, and of great service in humoral asthma's, coughs, and other disorders where thick phlegm abounds. It is given in doses of two or three drams, along with some aromatic water, as that of cinnamon, to prevent the great nausea which it would otherwise be apt to excite. In large doses it proves emetic.

Simple oxymel. L.

526 Take of clarified honey, two pounds; distilled vinegar, one pint. Boil them in a glass vessel, with a slow fire, to the thickness of a syrup.

This preparation may be considered as analogous to the *syrupus aceti* of the Edinburgh pharmacopœia. It is not inferior in efficacy to many more elaborate compositions. It is an agreeable, mild, cooling medicine. It is often used in cooling detergent gargarisms, and not unfrequently as an expectorant.

Oxymel of garlic. Dan.

527 Take of garlic, cut in slices, an ounce and an half; caraway seeds, sweet fennel seeds, each two drams; clarified honey, ten ounces; vinegar, half a pint. Boil the vinegar for a little time, with the seeds bruised, in a glazed earthen vessel; then add the garlic, and cover the vessel close; when grown cold, press out the liquor, and dissolve in it the honey by the heat of a water bath.

This oxymel is recommended for attenuating viscid juices, promoting expectoration, and the fluid secretions in general. It is doubtless a medicine of considerable efficacy, though very unpleasant, the flavour of the garlic prevailing notwithstanding the addition of the aromatic seeds.

Pæloral oxymel. Brun.

528 Take of elecampane roots, one ounce; orris root, half an ounce; gum ammoniac, one ounce; vinegar, half a pint; clarified honey, one pound; water, three pints. Let the roots, cut and bruised, be boiled in the water till one third is wasted: then strain off the liquor; let it stand to settle; and having poured it off clear from the feces, add to it

the honey and the ammoniac, and gently boil them together, by gently boiling them.

The title of this composition expresses its medicinal virtues. It is designed for those disorders of the breast that proceed from a load of viscid phlegm, and obstructions of the pulmonary vessels. Two or three spoonfuls may be taken every night and morning, and continued for some time.

CHAP. XXV. *Powders.*

This form receives such materials only as are capable of being sufficiently dried to become pulverifiable without the loss of their virtue. There are many substances, however, of this kind, which cannot be conveniently taken in powder: bitter, acid, fetid drugs, are too disagreeable; emollient and mucilaginous herbs and roots are too bulky; pure gums do become tenacious in the mouth; fixed alkaline salts liquefy on exposing the composition to the air; and volatile alkalis exhale. Many of the aromatics, too, suffer a greater loss of their odorous principle when kept in powder; as in that form they no doubt expose a much larger surface to the air.

The dose of powders, in extemporaneous prescription, is generally about half a dram: it rarely exceeds a whole dram, and is not often less than a scruple. Substances which produce powerful effects in smaller doses are not trusted to this form, unless their bulk be increased by additions of less efficacy; those which require to be given in larger ones are better fitted for other forms.

The usual vehicle for taking the lighter powders is any agreeable thin liquid. The ponderous powders, particularly those prepared from metallic substances, require a more consistent vehicle, as syrups; for from thin ones they soon subside. Resinous substances, likewise are most commodiously taken in thick liquors; in thin ones they are apt to run into lumps, which are not easily again soluble.

General rules for making powders.

I. Particular care ought to be taken that nothing carious, decayed, or impure, be mixed in the composition of powders: the stalks and corrupted parts of plants are to be separated.

II. The dry aromatics ought to be sprinkled during their pulverization, with a few drops of any proper water.

III. The moister aromatics may be dried with a very gentle heat before they are committed to the mortar.

IV. Gums, and such other substances as are difficultly pulverifiable, should be pounded along with the drier ones, that they may pass the sieve together.

V. No part should be separated from the rest until the whole quantity put into the mortar has passed the sieve, and the several siftings mixed together; for those parts of the subject which are first powdered may prove different at least in degree of efficacy, from the rest.

VI. Powders of aromatics are to be prepared only in small quantities at a time, and kept in glass vessels very closely stopped.

If powders are long kept, and not carefully secured from the air, their virtue is in a great measure destroyed,

although the parts in which it consists should not in other circumstances prove volatile. Thus, though the virtues of ipecacuanha are so fixed as to remain entire even in extracts made with proper menstrua, yet if the powdered root be exposed for a long time to the air, it loses its emetic quality.

Aloetic powder. L.

- 530 Take of fecotorine aloes, one pound; white canella, three ounces. Rub them separately to powder, and then mix them.

This composition has long been known in the shops under the title of *hierri picra*. It furnishes us with an useful aloetic purgative, the canella operating as a good corrigent for the aloes. But it is more frequently employed as the basis of electuaries or pills, or of a tincture which was for a long time distinguished by the appellation of *saevæ tinctura*.

Aloetic powder with iron. L.

- 531 Take of fecotorine aloes, powdered, an ounce and an half; myrrh, powdered, two ounces; dry extract of gentian, vitriolated iron, of each, in powder, one ounce. Mix them.

In this powder we have an aloetic and chalybeate conjoined. It consists of nearly the same articles which formerly entered the composition of the *pilula cephractice chalybeata*, as they were called; and it is perhaps more frequently employed when brought to the form of pills by means of syrups than in powder: but in either way it is an useful medicine, and is particularly employed with advantage in cases of obstructed menstruation.

Aloetic powder with guaiacum. L.

- 532 Take of fecotorine aloes, one ounce and an half; gum guaiacum, one ounce; aromatic powder, half an ounce. Rub the aloes and gum guaiacum separately to powder; then mix all the ingredients together.

In the guaiacum as well as the aloes, we have a warm gummy resinous purgative: and both are corrected, as well as more minutely divided, from their combination with the aromatics. This therefore furnishes us with an useful purgative; but when taken only in small doses, its chief effect is that of promoting perspiration. It is, however, more frequently employed in the form of pills than in the state of powder; and indeed it consists of nearly the same ingredients which constituted the *pilula aromatica* of the former edition of the London pharmacopœia.

Aromatic powder. L.

- 533 Take of cinnamon, two ounces; smaller cardamom seeds, hulled, ginger, long pepper, of each one ounce. Rub them together to a powder.

Aromatic powder, or aromatic spices. E.

Take of nutmegs, lesser cardamom seeds, ginger, each two ounces. Beat them together into a powder, to be kept in a phial well shut.

Both these compositions are agreeable, hot, spicy medicines; and as such may be usefully taken in cold phlegmatic habits and decayed constitutions, for warming the stomach, promoting digestion, and strengthening

the tone of the viscera. The dose is from ten grains to a scruple and upwards. The first is considerably the warmest. This principally arises from the quantity of long pepper which it contains. But it is perhaps to be doubted whether from this article any advantage be derived; and a powder not inferior to either might, we think, be formed, by substituting cassia for the cinnamon employed by the one college, or the nutmegs by the other.

Compound powder of asarabacca. L.

- Take of the dry leaves of the asarabacca, sweet marjoram, Syrian herb mallich, dry flowers of lavender, each one ounce. Powder them together.

534

Sternutatory, or cephalic powder. E.

Take of the leaves of asarum, three parts; marjoram, one part. Beat them together into a powder.

Though the former of these powders be more compounded than the latter, yet they differ very little. They are both agreeable and efficacious errhines, and superior to most of those usually sold under the name of *herb snuff*. They are often employed with great advantage in cases of obstinate headach, and of ophthalmias resisting other modes of cure. Taken under the form of snuff to the extent of five or six grains at bed-time, they will operate the succeeding day as a powerful errhine, inducing frequent sneezing, but still more a large discharge from the nose. It is, however, necessary, during their operation, to avoid exposure to cold.

Powder of ceruse. L.

- Take of ceruse, five ounces; farcocoll, one ounce and an half; tragacanth, half an ounce. Rub them together into powder.

535

This composition is the *trochisci alli* of Rhazes brought back to its original simplicity with regard to the ingredients, and without the needless trouble of making it into troches. It is employed for external purposes, as in collyria, lotions, and injections, for repelling acrimonious humours, and in inflammations.

Compound powder of crabs claws. L.

- Take of crabs claws, prepared, one pound; chalk, red coral, each prepared, three ounces. Mix them.

536

These powders have lost several of their ingredients without any injury to their virtues; and possibly they would still bear a farther reduction, for the crabs eyes and chalk are by themselves at least as effectual as any composition of them with coral. And perhaps every purpose to be obtained from them may be accomplished by a more simple absorbent, as the chalk powder afterwards to be mentioned, or the powder of the *lappilli cancerorum*.

Compound powder of contrayerva. L.

- Take of contrayerva, powdered, five ounces; compound powder of crabs claws, one pound and an half. Mix them.

537

This powder was formerly directed to be made up into balls with water, and was then called *lapis contrayervæ*; a piece of trouble now laid aside as needless, for it was necessary to reduce the balls into powder again

Preparations and Compositions.

again before they could be used. Nor did that form contribute, as has been imagined to their preservation; for it is scarcely to be supposed that the powder will lose more by being kept for a reasonable length of time in a close-stopt glass than the balls will in the humectation with water and exsiccation in the air before they are fit for being put by to keep. The medicine has much better claim to the title of an alexipharmac and sudorific than the foregoing compositions. The contrayerva by itself proves very serviceable in low fevers, where the *vis vite* is weak, and a diaphoresis to be promoted. It is possible that the crabs claws are of no farther service than as they divide this powerful ingredient, and make it sit more easily on the stomach.

Compound powder of chalk.

- 538 Take of prepared chalk, half a pound; cinnamon four ounces; tormentil, gum-arabic, of each three ounces; long pepper, half an ounce. Powder them separately, and mix them.

Chalk powder. E.

Take of white chalk, prepared, four ounces, nutmeg, half a dram; cinnamon, one dram. Mix and make them into a powder; which may supply the place of the cardialgic troches.

The addition of the aromatics in the above formula, coincides with the general intention of the remedy which is indicated for weakness and acidity in the stomach; and in loosens from acidity.

Compound powder of chalk with opium. L.

Take of compound powder of chalk, eight ounces; hard purified opium, powdered, one dram and an half. Mix them.

From the addition of the opium this remedy becomes still more powerful than the above in restraining diarrhœa.

Compound powder of ipœacuanha. L.

- 539 Take ipœacuanha and hard purified opium, of each, powdered, one dram; vitriolated kali, powdered, one ounce. Mix them.

Sudorific, or Dover's powder. E.

Take of vitriolated tartar, three drams; opium, root of ipœacuanha powdered, of each one scruple. Mix and grind them accurately together, so as to make an uniform powder.

The vitriolated tartar, from the grittiness of its crystals, is perhaps better fitted for tearing and dividing the tenacious opium than any other salt; this seems to be its only use in the preparation. The operator ought to be careful that the opium and ipœacuanha shall be equally diffused through the whole mass of powder, otherwise different portions of the powder must have differences in degree of strength.

The hard purified opium, directed by the London college, is, from this circumstance preferable to opium in its ordinary state, employed by the Edinburgh college.

This powder is one of the most certain sudorifics

Vol. XIV.

that we know of; and as such, was recommended by Dr Dover as an effectual remedy in rheumatism. Modern practice confirms its reputation, not only in rheumatism, but also in dropy and stundy other distempers where it is often difficult by other means to produce a copious sweat. The dose is from five to ten or twelve grains, according as the patient's stomach and strength can bear it. It is convenient to avoid much distemper immediately after taking it, otherwise it is very apt to be rejected by vomiting before any other effects are produced.

Compound powder of jalap. E.

Take of jalap root, one ounce; crystals of tartar, two ounces. Mix, and diligently grind them together for some time, so as to form a very fine powder.

The use of the crystals in this preparation is to break down and divide the jalap into very minute particles, whereby its operation is thought to be moderated; and on this account the two articles are directed to be pounded together, and not separately. But whether from this circumstance any advantage arises or not, there can be no doubt that this combination furnishes us with a very useful and active purgative, in every case where it is necessary to produce both a full evacuation of the intestinal canal, and a free discharge from the system in general, under the form of catharsis.

Compound powder of myrrh. L.

Take of myrrh, dried savin, dried rue, Russian castor, of each, one ounce. Rub them together into a powder.

This is a reformation of the troches of myrrh, a composition contrived by Rhazes against uterine obstructions. It may be taken in any convenient vehicle, or made into boluses, from a scruple to a dram or more, two or three times a-day.

Opate powder. L.

Take of hard purified opium, powdered, one dram; burnt and prepared hartshorn, nine drams. Mix them.

The hartshorn is here intended merely to divide the opium, and to give it the form of powder, although it may perhaps have also some influence in rendering the opium more active from destroying acid in the stomach. But whether in this way it has any effect or not, there can be no doubt that it is a very convenient formula for the exhibition of opium in powder; which on some occasions is preferable to its being given either in a liquid form or in that of pills. As ten grains of this powder contain precisely one of the opium, the requisite dose may be easily adapted to the circumstances of the case. It is often successfully employed as a sweating powder; and has not, like Dover's powder, the effect of inducing sickness or vomiting.

Compound powder of scammony.

Take of scammony, hard extract of jalap, each two ounces; ginger, half an ounce. Powder them separately, and mix them. L.

3 G

Take

Preparations and Compositions.

Take of scammony, crystals of tartar, each two ounces; mix, and grind them diligently into a powder. *E.*

It is much to be regretted, that in the pharmacopœias published by authority in Britain, two compositions should be distinguished by the same name, differing considerably from each other in their nature and degree of activity.

The compound powder of scammony in the last edition of the London pharmacopœia differed considerably from the present: For there, the only addition was calcined hartshorn, intended merely for the division of the scammony. This purpose is still better answered by the crystals of tartar, which at the same time conpire with the operation of the scammony as a purgative. But the addition of jalap and ginger, according to the present formula of the London pharmacopœia, gives not only a purgative considerably different, but increases also the heating quality of the medicine, while the cream of tartar has an evident refrigerant power. Both may on occasions be useful, but we think that in most cases the Edinburgh formula will be found preferable.

In editions of our pharmacopœias of still older date, this powder was prepared with another very active ingredient, diaphoretic antimony. It was much celebrated as distinguished by the name of its inventor, being called from its first publisher, *Cornachini's powder*. In a former edition of the Edinburgh pharmacopœia it was thus directed to be prepared:

Take of diaphoretic antimony, cream of tartar, scammony, each equal parts. Make them into a powder.

This may be given to the quantity of a dram or more. In other prescriptions, the tartar and antimonial calx bear nearly the same proportion to the scammony as the calcined hartshorn did in the London pharmacopœia. It appears probable that neither of these ingredients are of any farther use, than as they divide the texture of the scammony; though Cornachini supposes very considerable advantage from some deobstruent quality in the tartar, whereby the vessels shall be opened, and the noxious humours prepared for expulsion: and from the preparation of antimony, though it have no sensible operation, he expects some share of the same success which sometimes attends the rougher preparations of that mineral.

Both the present formulæ may, however, be considered as possessing all the advantages of Cornachini's powder.

Powder of scammony with aloes. L.

544

Take of scammony, six drams; hard extract of jalap, socotrine aloes, of each an ounce and an half; ginger, half an ounce. Powder them separately, and mix them.

In this formula, the combination of scammony, jalap, and aloes, furnishes a very active purgative, which, with some intention at least, may be preferable to either of the preceding. Taken from five to ten grains, it will operate as a purgative even in cases of obstinate costiveness.

Powder of scammony with calomel. L.

545

Take of scammony, half an ounce; calomel, double-

refined sugar, of each two drams. Rub them separately to a powder, and then mix them.

In this formula, we have the scammony in a more simple state united with such a proportion of calomel as must very considerably aid its purgative power. And accordingly it may be employed with advantage, both in cases of obstinate costiveness and in dropsical affections, where a considerable discharge is required from the system.

Compound powder of fenna. L.

Take fenna, crystals of tartar, of each two ounces; scammony, half an ounce; ginger, two drams. Rub the scammony by itself, rub the rest together into a powder, and then mix them all.

This powder is given as a cathartic, in the dose of two scruples or a dram. The spice is added, not only to divide, but to warm the medicine, and make it fit easier on the stomach. The scammony is used as a stimulus to the fenna; the quantity of the latter necessary for a dose, when not assisted by some more powerful material, being too bulky to be conveniently taken in this form.

The composition of this medicine is now considerably simplified by the rejection both of cinnamon and cloves, as the ginger alone is found fully to answer the intention of the view.

Syptic powder. E.

Take of alum, an ounce and an half; gum-kino, three drams. Grind them together into a fine powder.

In former editions of our pharmacopœia, a powder of this kind was directed to be made with alum and dragon's blood, and was long in repute as an astringent, under the title of *Helvetius's syptic powder*. The gum-kino is judiciously substituted for the dragon's blood, as being a much more powerful and certain astringent. The chief use of this powder is in hæmorrhagies, especially of the uterus.

Compound powder of tragacanth. L.

Take of tragacanth powdered, gum-arabic, starch, each an ounce and a half; double refined sugar, three ounces. Rub them together into a powder.

This composition is somewhat simplified by the rejection of the marshmallow, and liquorice root, which formerly entered it. But this has not probably produced any diminution of its medical properties. It operates as a mild emolient; and hence becomes serviceable in hectic cases, tickling coughs, strangury, some kinds of alvine fluxes, and other disorders proceeding from a thin acrimonious state of the humours, or an abrasion of the mucus of the intestines; they soften, and give a greater degree of consistency to the former, and defend the latter from being irritated or excoriated by them. All the ingredients coincide in these general intentions. The dose is from half a dram to two or three drams, which may be frequently repeated.

Antihelminthic powder. Gen.

Take of the flowers of tanfy, worm-seeds, each three drams; sal martis, one dram. Mix them.

Both

Preparations and Compositions.

546

547

548

549

Preparations and Compositions.

Both the tanfy and worm seed poffefs a confiderable degree of anthelmintic power, which is not a little increafed by the falt of fteel. And from this combination more effect in the expulfion of worms, particularly of the lumbrici, may be expected, than from any of the articles taken by themfelves. This powder may be taken to the extent of half a dram or upwards for a dofe, proportioned to the age and circumftances of the patient.

Powder againft the bite of a mad-dog. Brun.

550 Taste of afh-coloured ground liverwort, two ounces; black pepper, one ounce. Beat them together into a powder.

The virtue for which this medicine has been celebrated, is expreffed in its title: the dofe is a dram and a half, to be taken in the morning fasting, in half a pint of cows milk warm, for four mornings together.

At one period it was held, on the recommendation of Dr Mead and other eminent practitioners, in very high efteem. Now, however, it has fallen into fuch difrepute, as to be banifhed from moft of the modern pharmacopœias.

Compound powder of arum. Succ.

551 Take of arum root, frefh dried, two drams; yellow water-flag roots, burnt faxifrage roots, each one dram; white canella, a dram; falt of wormwood, one fcruple. Beat them into a powder, which is to be kept in a clofe veflel.

In former editions of the London pharmacopœia, one of the ingredients in this compofition was called *acoris vulgi* or *vulgaris*; a name which has been applied, by different writers, both to *calamus aromaticus* and to *gladiolus luteus*, or common yellow water-flag. In this uncertainty, the compounders generally took the former. But as the medicine was firft contrived by a German phyfician (Birkmann), and as in fome of the German pharmacopœias, the *acoris vulgaris* is explained to be the water-flag, the Swedifh college have rather, in conformity to the original prefcription, than from any opinion of the virtues of the water flag (which appears, when the root is dried and powdered, to be very inconfiderable), made choice of this laft and expreffed it by the name which more clearly diftinguifhes it from the other. The caution of keeping the powder in a clofe veflel is very neceffary; for if it be expofed to the air, the alkaline falt, imbibing moiſture, would run into a liquid ſtate. Two alkaline falts have been generally directed; but, as they differ from each other only in name, one of them is here juſtly omitted, and fupplied by a proportional increafe of the other. Crabs eyes were originally an article in this compofition, but probably ferved little other purpoſe than to increafe its volume.

Agreeable to the above remark, the college of Edinburgh, in a revival of their pharmacopœia, had omitted the crabs-eyes, and continued the former practice of uſing *calamus aromaticus* for the *acoris vulgaris*. They had likewiſe exchanged the cinnamon for the white canella: and the alkaline falt for a neutral one, better ſuited to the form of a powder. Their formula was as follows:

Take of arum roots, newly dried, two ounces; calamus aromaticus, burnt faxifrage roots, each one ounce; white canella, fix drams; vitriolated tartar, two drams. Mix and make them into a powder.

Preparations and Compositions.

This article which had formerly a place alfo in the London pharmacopœia, is ſtill retained in ſome of the beſt foreign ones: But it is now altogether rejected from our pharmacopœias.

The compound powder of arum was originally intended as a ſtomachic; and in weakneſſes and relaxations of the ſtomach, accompanied with a ſurcharge of viſcid humors, it is doubtleſs a very uſeful medicine. It frequently has alſo good effects in rheumatic cafes: the doſe may be from a ſcruple to a dram, two or three times a day, in any convenient liquor. It ſhould be uſed as freſh as poſſible, for its virtue ſuffers greatly in keeping; the arum root in particular, its capital ingredient loſes the pungency in which its efficacy principally conſiſts.

Digſtive powder. Succ.

Take of bitter purging ſalts, rhubarb, each equal parts. Mix them.

552

In this compoſition, the falt will brifken the operation of the rhubarb as a cathartic, and the aſtringency of the latter will tend to increaſe the tone of the ſtomach; hence, in conſequence of evacuating, and at the ſame time ſtrengthening the alimentary canal, it may be preſumed to have conſiderable influence in promoting digeſtion.

Dyſenteric powder. Dan.

Take of rhubarb, one ounce; calcined hartſhorn, half an ounce; gum arabic, three drams; caſcarilla bark, two drams. Mix them, and reduce them to a very fine powder.

553

Here the rhubarb is combined with an other powerful tonic, the caſcarilla; and while the calcined hartſhorn ſerves to neutralize acid, the gum-arabic will operate as a demulcent. This compoſition therefore may be very uſeful in dyſenteric cafes, after the violence of the diſeaſe has been overcome, and when there remains a debilitated and abraded ſtate of the inteſtinal canal.

Fumigation powder. Roſſ.

Take of olibanum, amber, maſtich, each three parts; ſtorax, two parts: benzoin, labdanum, each one part. Mix them into a groſs powder.

554

This powder is intended for the purpoſe of fumigation: and when burnt it gives out a fragrant odour; hence it may be ſucceſsfully employed for combating diſagreeable ſmells, and counteracting putrid or other noxious vapours diffuſed in the atmoſphere.

Powder for infants. Succ.

Take of magnesia alba, one ounce, rhubarb, reduced to a very fine powder, one dram. Let them be mixed.

555

This powder is very uſeful for deſtroying acid, and at the ſame time reſtoring the diminiſhed tone of the alimentary canal: hence it is often advantageouſly employed in cafes of diarrhœa, which depend on theſe

Preparations and Compositions.

morbid conditions. And it is in general a circumstance of considerable advantage, that it does not tend to check looseness very suddenly. It is particularly useful with infants, and hence the origin of the name here affixed to it.

Nitrous powder. Succ.

- 556 Take of purified nitre, three ounces; salt of ferrel, one ounce; double-refined sugar, ten ounces. Let them be mixed.

This is a very convenient and agreeable form of exhibiting nitre: for while the sugar serves not only to divide and diffuse it, but also to correct its taste, the salt of ferrel adds to its refrigerant power.

Purging Peruvian powder. Gen.

- 557 Take of the powder of Peruvian bark, one ounce; powder of rhubarb, powder of sal ammoniac, each one dram and a half.

It has been imagined by many, that particular advantage resulted from uniting the Peruvian bark with sal ammoniac: and there can be no doubt, that in some cases inconvenience results from the bark, in consequence of its binding the belly. There are therefore circumstances in which the combination here proposed may perhaps be proper; but there is reason to believe that the benefit of the sal ammoniac is more imaginary than real; and it not unfrequently happens, that we are disappointed of the benefit which might otherwise be derived from the bark, in consequence of its proving even of itself a purgative. Hence, in perhaps a majority of cases, the exhibiting it with the additions here proposed will be rather prejudicial than otherwise.

Thebaic powder. Succ.

- 558 Take of opium, half a scruple; purified nitre, five scruples and a half; refined sugar, one ounce. Mix them together into a powder.

In this powder those inconveniences which sometimes result from opium may with certain constitutions be corrected, in consequence of the refrigerant power of nitre; and hence it may prove a very useful sedative powder. The sugar is intended merely to give form to the medicine; and in its state of combination, each dram of it contains a grain of opium; so that a practitioner has it in his power easily to regulate the dose according to circumstances.

Sponge-powder. Gen.

- 559 Take of burnt sponge, powdered, common salt, each three drams. Mix them, and divide into twelve powders.

We have formerly noticed the manner of burning sponge. (see n^o 98.) It is of very considerable service in scrofulous affections, and particularly in the cure of the bronchocele. It has of late been highly celebrated for these purposes by Mr Wilmer, under the title of the *Coventry remedy*. There it was sometimes employed merely in its pure state, combined with a sufficient quantity of honey, to form it into a bolus; sometimes it was given united with calcined cork and pumice-stone. What advantage,

however, it could have derived from these additions it is difficult to conceive; nor can we readily see how it will be improved by the addition of common salt here proposed: for this may probably lead to new combinations, materially altering the qualities of those salts which the sponge itself contains; and on which its virtues, as far as it has any, must depend. At the same time, for any experience which we ourselves have had, we are inclined to think that those virtues which have been attributed to burnt sponge are more imaginary than real.

Preparations and Compositions.

CHAP. XXVI. *Troches.*

TROCHES and lozenges are composed of powders made up with glutinous substances into little cakes, and afterwards dried. This form is principally used for the more commodious exhibition of certain medicines, by fitting them to dissolve slowly in the mouth, so as to pass by degrees into the stomach; and hence these preparations have generally a considerable proportion of sugar or other materials grateful to the palate. Some powders have likewise been reduced into troches, with a view to their preparation; though possibly for no very good reasons; for the moistening and afterwards drying them in the air, must on this account be of greater injury than any advantage accruing from this form can counterbalance.

563

General Rules for making Troches.

1. The three first rules laid down for making powders, are also to be observed in the powders for troches.
2. If the mass proves so glutinous as to stick to the fingers in making up, the hands may be anointed with any convenient sweet or aromatic oil; or else sprinkled with powder of starch, or of liquorice, or with flour.
3. In order to thoroughly dry the troches, put them on an inverted sieve, in a shady airy place, and frequently turn them.
4. Troches are to be kept in glass vessels, or in earthen ones well glazed.

Troches of Starch. L.

Take of starch, an ounce and an half; liquorice, six drams; florentine orris, half an ounce; doubt refined sugar, one pound and a half. Rub these to powder, and, by the help of tragacanth, dissolved in water, make troches. They may be made, if so chosen, without the orris.

561

White pectoral troches. E.

Take of purest sugar, one pound; gum arabic, four ounces; starch, one ounce; flowers of benzoin, half a dram. Having beat them all into a powder, make them into a proper mass with rose-water, so as to form troches.

These compositions are very agreeable pectorals, and may be used at pleasure. They are calculated for softening acrimonious humours, and allaying the tickling in the throat which provokes coughing.

Although not only the name but the composition also

Preparations and Compositions.

also in the London and Edinburgh pharmacopœias be somewhat different, yet their effects are very much the same.

Troches of liquorice. L.

- 562 Take of extract of liquorice, double-refined sugar, each ten ounces; tragacanth, powdered, three ounces. Make troches by adding water.

Black pectoral troches. F.

Take of extract of liquorice, gum arabic, each four ounces; white sugar, eight ounces. Dissolve them in warm water, and strain; then evaporate the mixture over a gentle fire till it is of a proper consistence for being formed into troches.

These compositions are designed for the same purposes as the white pectoral troches above described. In foreign pharmacopœias there are some other troches of this kind, under the titles of *Trochysci bechici favi* and *rubri*; the first are coloured with saffron, the latter with oleo aromatic. The dissolving and straining the extract of liquorice and gum arabic, as now ordered in the last of the above prescriptions, is a considerable improvement; not only as they are by that means more uniformly mixed than they can well be by beating, but likewise as they are thereby purified from the heterogeneous matters, of which both those drugs have commonly no small admixture.

Pectoral troches with opium. E.

- 563 Take of pure opium, two drams; balsam of Peru, one dram; tincture of Tolu, three drams. Grind the opium with the balsam and tincture previously mixed, till it be thoroughly dissolved; then add by degrees, of common syrup, eight ounces; extract of liquorice, softened in warm water, five ounces. While beating them diligently, gradually sprinkle upon the mixture five ounces of powdered gum arabic. Exsiccate so as to form troches, each weighing ten grains.

The directions for preparing the above troches are so full and particular, that no further explanations are necessary. Six of the troches prepared in the manner here ordered, contain about one grain of opium. These troches are medicines of approved efficacy in tickling coughs depending on an irritation of the fauces. Besides the mechanical effect of the inviscating matters and involving acrid humours, or lining and defending the tender membranes, the opium must, no doubt, have a considerable share, by more immediately diminishing the irritability of the parts themselves.

The composition of these troches, however, would perhaps be improved by the omission of the balsam of Peru: for although here directed only in small quantity, yet it gives a taste to the troches which is to many people very disagreeable; and it is at the same time probable that it adds very little, if any thing, to the efficacy of the medicine.

Troches of nitre.

- 564 Take of purified nitre, powdered, four ounces; double-refined sugar, powdered, one pound; tragacanth,

powdered, six ounces. With the addition of water, make troches. L.

Take of nitre, purified, three ounces; double-refined sugar, nine ounces. Make them into troches with mucilage of gum tragacanth. E.

This is a very agreeable form for the exhibition of nitre; though, when the salt is thus taken without any liquid (if the quantity be considerable), it is apt to occasion uneasiness about the stomach, which can only be prevented by large dilution with aqueous liquors. The troches of nitre have been said to be employed with success in some cases of difficult deglutition.

Troches of sulphur.

Take of washed flowers of sulphur, two ounces; double-refined sugar, four ounces. Rub them together; and, with the mucilage of quince-seeds, now and then added, make troches. L.

Take of flowers of sulphur, two ounces; flowers of benzoin, one scruple; white sugar, four ounces; facitious cinnabar, half a dram. Beat them together, and add mucilage of gum tragacanth as much as is sufficient. Mix and make them into troches according to art. E.

These compositions are to be considered only as agreeable forms for the exhibition of sulphur, no alteration or addition being here made to its virtues; unless that, by the flowers of benzoin in the second prescription, the medicine is supposed to be rendered more efficacious as a pectoral.

The facitious cinnabar seems chiefly intended as a colouring ingredient.

Troches of chalk. L.

Take of chalk prepared, four ounces; crabs-claws, prepared, two ounces; cinnamon, half an ounce; double-refined sugar, three ounces. These being rubbed to powder, add mucilage of gum arabic, and make troches.

Troches of magnesia. L.

Take of burnt magnesia, four ounces; double refined sugar, two ounces; ginger, powdered, one scruple. With the addition of mucilage of gum arabic, make troches.

These compositions are calculated against that uneasy sensation at the stomach, improperly called the *heartburn*; in which they often give immediate relief, by absorbing and neutralizing the acid juices that occasion this disorder. The absorbent powders here used are of the most powerful kind. The former has in general the effect of binding, the latter of opening, the belly; and from this circumstance the practitioner will be determined in his choice, according to the nature of the case which he may have occasion to treat.

Red lead troches. Dan.

Take of red lead, half an ounce; corrosive sublimate mercury, one ounce; crumb of the finest bread four ounces. Make them up with rose-water into oblong troches.

These

Preparations and Compositions.

565

566

567

Preparations and Compositions

These troches are employed only for external purposes as of aretes: they are powerfully such, and require a good deal of caution in their use.

Troches of catechu. B. P. U.

568 Take of catechu, one ounce; white sugar candy, two ounces; ambergris, musk, each ten grains; mucilage of gum tragacanth, as much as is sufficient. Make them into trochys.

This medicine has long been in esteem as a first restringent; and restringent thus gradually received into the stomach produce better effects than when an equal quantity is taken down at once. These troches would be more palatable, and perhaps not less serviceable, were the musk and ambergris omitted.

CHAP. XXVI. *Pills.*

569 To this form are peculiarly adapted those drugs which operate in a small dose, and whose nauseous and offensive taste or smell require them to be concealed from the palate.

Pills dissolve the most difficultly in the stomach, and produce the most gradual and lasting effects of all the internal forms. This is in some cases of great advantage, in others it is a quality not at all desirable; and sometimes may even be of dangerous consequence, particularly with regard to emetics; which, if they pass the stomach undissolved, and afterwards exert themselves in the intestines, operate there as violent cathartics. Hence emetics are among us scarcely ever given in pills; and hence to the resinous and difficultly soluble substances, saponaceous ones ought to be added, in order to promote their solution.

Gummy resins, and inspissated juices are sometimes soft enough to be made into pills without addition; where any moisture is requisite, spirit of wine is more proper than syrups or conserves, as it unites more readily with them, and does not sensibly increase their bulk. Light dry powders require syrup or mucilages; and the more ponderous, as the mercurial and other metallic preparations, thick honey, conserve or extracts.

Light powders require about half their weight of syrup, of honey, about three-fourths their weight, to reduce them into a due consistence for forming pills. Half a dram of the mass will make six or seven pills of a moderate size.

General rules for making pills.

1. Gums and inspissated juices are to be first softened with the liquor prescribed; then add the powders, and continue beating them all together till they be perfectly mixed.
2. The masses for pills are best kept in bladders, which should be moistened now and then with some of the same kind of liquid that the mass was made up with, or with some proper aromatic oil.

Ethiopic pills. E.

570 Take of quicksilver, six drams; golden sulphur of antimony, resin of guaiacum, honey, each half an ounce. Grind the quicksilver with the honey, in a

glass mortar, until the mercurial globules entirely disappear; then add the golden sulphur and guaiacum, with as much mucilage of gum arabic as is sufficient to make the mixture into a mass of the proper consistence for forming pills.

Preparations and Compositions

These pills are much more efficacious than those of a former edition; the ethiops mineral, there ordered, being exchanged for a more active composition. In their present form they resemble Dr Plummer's pills, described in the Edinburgh Essays, and afterwards to be mentioned. To it they are preferable in one respect, that they are less apt to run off by stool. They are an useful alterative both in cutaneous and venereal disorders. One fourth-part of the quantity above prescribed may be made into sixty pills; of which from one to four may be taken every night and morning, the patient keeping moderately warm during the whole time that this course is continued.

Pills of aloes. L.

Take of socotorine aloes, powdered, an ounce; extract of gentian, half an ounce; syrup of ginger, as much as is sufficient. Beat them together.

571

Aloetic pills. E.

Take of socotorine aloes, in powder, thick extract of gentian, each two ounces; make them into a mass with simple syrup.

These pills were formerly directed to be made with Castile soap; from a notion which Boerhaave and some others were very fond of, that soap promoted the solution of resinous and several other substances in the stomach. This, however, seems to be a mistake; and, on the contrary, it is highly probable that the alkaline part of the soap is in most instances separated from the oily by the acid in the stomach; by which decomposition the soap may possibly retard instead of promoting the solution of the aloes. These pills have been much used as warming and stomachic laxatives: they are very well suited for the costiveness so often attendant on people of sedentary lives. Like other preparations of aloes, they are also used in jaundice, and in cases of obstructed menses. They are seldom used for producing full purging; but if this be required, a scruple or half a dram of the mass may be made into pills of a moderate size for one dose.

Pills of aloes with myrrh. L.

Take of socotorine aloes, two ounces; myrrh, saffron, of each one ounce; syrup of saffron, as much as is sufficient. Rub the aloes and myrrh separately to powder; afterwards beat them all together.

572

The common pills, vulgarly called Rufus's pills. E.

Take of socotorine aloes, two ounces; myrrh, one ounce; saffron, half an ounce. Beat them into a mass with a proper quantity of syrup.

These pills have long continued in practice, without any other alteration than in the syrup with which the mass is made up, and in the proportion of saffron. In our last pharmacopœia, the syrup of wormwood was ordered, which is here judiciously exchanged by the London college for that of saffron; this preserving and

Preparations and Compositions.

and improving the brightness of colour in the medicine, which is the characteristic of its goodness. The saffron, in the composition which is attributed to Rufus, is equal in quantity to the myrrh; and in these proportions the pill was received in our first pharmacopœia. As the diminution afterwards made in the saffron was grounded on very absurd reasons, viz, "lest the former quantity should occasion a spasmus cynicus," the London college have now again increased it, and restored the pill to its original form. The virtues of this medicine may be easily understood from its ingredients. These pills, given to the quantity of half a dram or two scruples, prove considerably cathartic, but they answer much better purposes in smaller doses as laxatives or alteratives.

Colocynth pills with aloes, commonly called Coccie. E.

- 573 Take socotorine aloes, scammony, of each two ounces; sal polychrest, two drams; colocynth, one ounce; oil of cloves, two drams. Reduce the aloes and scammony into a powder with the salt; then let the colocynth beat into a very fine powder, and the oil be added; lastly, make it into a proper mass with mucilage of gum arabic.

In these pills we have a very useful and active purgative; and where the simple aloetic pill is not sufficient for obviating costiveness, this will often effectually answer the purpose. Little of their activity can depend upon the salt which enters the composition; but it may assist in dividing the active parts of the other articles, particularly the aloes and scammony. These pills often produce a copious discharge in cases of obstinate costiveness, when taken to the extent only of five or ten grains; but they may be employed in much larger doses. They are, however, seldom used with the view of producing proper catharsis. Half a dram of the mass contains about five grains of the colocynth, ten of the aloes, and ten of the scammony.

Copper pills. E.

- 574 Take of cuprum ammoniacum, sixteen grains; crumb of bread, four scruples; spirit of sal ammoniac, as much as is sufficient to form them into a mass, which is to be divided into thirty two equal pills.

These pills had formerly the name of *Pilule ceruleæ*, but they are now with greater propriety denominated from the metal which is their basis.

Each of these pills weighs about three grains, and contains somewhat more than half a grain of the cuprum ammoniacum. The above pills seem to be the best form of exhibiting this medicine. See *CUPRUM ammoniacale*, and CHEMISTRY, n° 1034.

Gum pills.

- 575 Take of galbanum, opopanax, myrrh, fagapenum, each one ounce: asafœtida, half an ounce; syrup of saffron, as much as is sufficient. Beat them together. *L.*

Take asafœtida, galbanum, myrrh, each one ounce; rectified oil of amber, one dram. Beat them into a mass with simple syrup. *E.*

The pills are designed for antihysterics and emme-

nagogues, and are very well calculated for answering these intentions; half a scruple, a scruple or more, may be taken every night or oftener. The fetid pills of our former pharmacopœia were considerably purgative; the purgative ingredients are now omitted, as the physician may easily, in extemporaneous prescription, compound these pills with cathartic medicines, in such proportions as particular cases shall require.

Quicksilver pills.

Take purified quicksilver, extract of liquorice, having the consistence of honey, of each two drams; liquorice, finely powdered one dram. Rub the quicksilver with the extract of liquorice until the globules disappear: then, adding the liquorice-powder, mix them together.

576

Mercurial pills. E.

Take of quicksilver, honey, each one ounce; crumb of bread, two ounces. Grind the quicksilver with the honey in a glass mortar till the globules disappear, adding occasionally a little simple syrup; then add the crumb of bread, and beat the whole with water into a mass, which is to be immediately divided into four hundred and eighty equal pills.

The quicksilver was formerly directed to be ground with resin of guaiacum and Castile soap. The former was supposed to coincide with the virtues of the mercury, and the latter was used chiefly to divide the globules of mercury. For this last intention Dr Saunders found that honey, the substance here ordered by the Edinburgh college, is of all he tried the most effectual; but we would suppose with this gentleman, that something farther is done in this process than the mere division of the mercurial globules, and that part of the quicksilver is as it were amalgamated with the honey, or brought to a state similar to that in Plenck's solution. The same effect will take place when the pills are prepared with extract of liquorice now directed by the London college.

The mercurial pill is one of the best preparations of mercury, and may in general supersede most other forms of this medicine. It is necessary to form the mass immediately into pills, as the crum soon becomes too hard for that purpose. Soap was undoubtedly a very improper medium for triturating the mercury; it is not only too hard for that purpose, but when the preparations entered the stomach, the alkaline part of the soap being engaged by the acid in that viscous, the mercury would in all probability be immediately separated. The honey and bread can only be changed by the natural powers of digestion, and can never oppress the stomach. The dose of the pills is from two to four or six in the day, according to the effects we wish to produce.

Jalap pills. E.

Take of extract of jalap, two ounces; aromatic powder, half an ounce. Beat them into a mass with simple syrup.

577

This is an useful and active purgative, either for evacuating the contents of the intestinal canal, or producing a discharge from the system in general.

One

Prepara-
tions and
Composi-
tions.

One of the same kind, with powdered jalap in substance instead of the extract, is used in some of our hospitals as a cheap and effectual purge.

Plummer's pill. E.

- 578 Take of sweet mercury, precipitated sulphur of antimony, each six drams; extract of gentian, white Spanish soap, each two drams. Let the mercury be triturated with the sulphur till they be thoroughly mixed, then add the extract, and form a mass with simple syrup.

These pills were recommended to the addition of the publick about forty years ago by Dr Plummer, whose name they still bear. He represented them in a paper which he published in the Edinburgh Medical Essays, as a very useful alterative; and on his authority they were at one time much employed; but they are now less extensively used than formerly. And although they still retain a place in the Edinburgh pharmacopœia, yet it is probable that every purpose to be answered by them may be more effectually obtained from the common mercurial pill, or from calomel in a more simple state.

Opium pills. L.

- 579 Take of hard purified opium, powdered, two drams; extract of liquorice, one ounce. Beat them until they are perfectly united.

Thebaic, commonly called Pacific pills. E.

Take of opium, half an ounce; extract of liquorice, two ounces; Cassia seeds, an ounce and a half; Jamaica pepper, one ounce. Soften the opium and extract separately with proof-spirit, and having beat them into a pulp, mix them; then add the soap, and the pepper beat into a powder; and lastly having beat them well together, form the whole into a mass.

These two compositions, though differing in several particulars may yet be considered as fundamentally very much the same. The first is a simple opiate, in which every five grains of the mass contains one of opium; and in the opium alone can we suppose that the activity of the medicine depends.

Although some of the articles contained in the latter composition may perhaps be supposed to operate as corrigentia, yet the former composition, which is the most simple, is in general preferable.

Pills similar to the second were contrived by a chemical erpinc, Starkey, and communicated by him to Matthews, under whose name they were some time ago greatly celebrated. The form here given differs considerably from the original, in omitting many ingredients of no great service. Nor indeed are any of the ingredients of much consequence, except the opium; their quantity being too inconsiderable to answer any useful purpose. Ten grains of the composition contain one of opium.

Squill-pills.

- 580 Take of fresh dried squills, powdered, one dram; ginger powdered, soap, of each three drams; ammoniacum, two drams; syrup of ginger, as much as is sufficient. Beat them together. L.

Take of gum ammoniac, lesser cardamom seeds, in powder, extract of liquorice, each one dram; dried root of squills, in fine powder, one scruple. Mix, and form them into a mass with simple syrup. E.

Prepara-
tions and
Composi-
tions.

These are elegant and commodious forms for the exhibition of squills, whether for promoting expectoration, or with the other intentions to which that medicine is applied. As the virtue of the compound is chiefly from the squills, the other ingredients are often varied in extemporaneous prescription; and probably no material difference takes place in the two forms here proposed excepting in the proportion of the squills, which in the former constitutes one ninth, in the latter one tenth, of the mass.

Stomachic pills. E.

- Take of rhubarb, one ounce; socotorine aloes, six drams; myrrh half an ounce; vitriolated tartar, one dram; essential oil of mint, half a dram; syrup of orange peel, a sufficient quantity. Make them into a mass.

581

This pill is intended for moderately warming and strengthening the stomach, and evacuating crude viscid humors. A scruple of the mass may be taken twice a-day.

Bacher's pills. Gen.

- Take of extract of black hellebore, purified myrrh, each one ounce; power of carduus benedictus, two scruples. Mix them into a mass according to art, to be dried in the air till it be fit for the formation of pills, each weighing one grain.

582

These pills have been strongly recommended as a most effectual remedy in dropical cases, and have been alleged to unite an evacuant and tonic power. Hence they have been considered as particularly suited to those cases where remarkable weakness and laxity occur. Under the hands of Mr Bacher the inventor, they acquired so great reputation, that, after a trial in the military hospitals at Paris, the receipt was purchased by the French king, and published by authority. But like many other nostrums since this publication, Bacher's pill has by no means supported the reputation which it had when kept a secret. The dose is varied according to circumstances, from one to thirty pills taken in the course of the day.

Pills of elaterium. Suec.

- Take of the purest gum ammoniac, two ounces; socotorine aloes, gamboge, each two drams; elaterium, half a dram. Mix them, by means of bitter tincture, into a mass, and let pills be formed, each weighing two grains.

583

This, as well as the former, is also a pill celebrated for the cure of dropical affections. And the elaterium from which it derives its name, is one of the most powerful evacuants in the way of catharsis. Here, however, it is united with such active articles, particularly the gamboge, as must make its effect somewhat doubtful. And we are inclined to think that a preferable formula for making the pills of elaterium, is to form it into a mass, with the extract of gentian. This is imagined to have some influence as correcting its effect,

in

Preparations and Compositions.

in exciting sickness. And when each pill is made to contain half a grain of the elaterium, the dose may be easily accommodated to the circumstances of the patient, one or two pills being taken every hour till they begin to operate.

The elaterium, whether under the form above-mentioned, or in the more simple state which has now been suggested, operates as a very powerful cathartic, often inducing the discharge of stagnant serum, when other remedies are found ineffectual. But it can be exhibited only in those cases where the patient still retains a considerable degree of strength.

Fetid pills. Succ.

584 Take of asafoetida, castor, each a dram and a half; salt of amber, half a dram; oil of hartthorn, half a scruple. Make them into a mass, with tincture of myrrh, to be divided into pills of two grains each.

These, like the gum-pills formerly mentioned, are chiefly used as an antihysteric and antispasmodic medicine; and they are particularly useful in counteracting spasmodic affections of the alimentary canal, especially those connected with flatulence. But the asafoetida is no less successful when exhibited in a more simple state, particularly when formed into pills with an equal quantity of soap, by the aid of simple syrup.

Gamboge pills. Dan.

585 Take of socotorine aloes, extract of black hellebore, sweet mercury, gamboge, each two drams; distilled oil of juniper, half a dram; syrup of buckthorn, as much as is sufficient for forming a mass of pills.

From the ingredients of which these pills are constituted, we need hardly remark, that they must prove a very powerful purgative. The gamboge, from which they derive their name is unquestionably a very active purge. But is not more so than the sweet mercury; and perhaps from an union of these two, as much might be expected as from the more compounded formula here adopted. Yet it is not improbable that the essential oil of juniper may in some degree operate as a corrigit.

Pills of corrosive sublimate mercury. Succ.

586 Take of corrosive sublimate, purified sal ammoniac, each one scruple; distilled water, as much as is sufficient to dissolve them; powder of the root of althea, sixteen scruples; honey, two drams. Mix them into a mass for the formation of pills, each weighing three grains.

Corrosive sublimate in substance was long considered as being so violent in its effects, that it could not with safety be taken internally; but for a considerable time it has been used with advantage under the form of solution, either in water or spirits. But to both these a considerable objection occurs from their disagreeable brassy taste. This objection is however entirely obviated, by reducing the solution, after it is formed, to a solid mass, by means of crumb of bread, or any proper powder: and by the aid of a little sal ammoniac, the solution may be made in a very small quantity of water; so that less of any solid intermedium

will be sufficient to bring it to a solid state. The formula here directed is well adapted to the purpose intended. Each of the pills contains about an eighth of a grain of the sublimate, the dose may be easily regulated according to the intention in view. And these pills are not infrequently employed with advantage, both in curable venereal and cutaneous affections, and for the expulsion of worms from the alimentary canal. With the latter of the intentions, a similar pill was particularly recommended by Dr Gardener, in a paper published in the Edinburgh Physical and Literary Essays; and although not received into our pharmacopœia, it has been frequently used at Edinburgh.

Tar pills. Dan.

Take any quantity of tar, and mix with it as much powdered cleampane root as will reduce it to a proper thickness for being formed into pills.

The powder here mixed with the tar, though of no great virtue, is nevertheless a very useful addition, not only for procuring it a due consistence, but likewise as it divides the resinous texture of the tar, and thus contributes to promote its solution by the animal juices. In the Edinburgh infirmary, half a dram of the mass, made into middle sized pills, is given every morning and evening in disorders of the breast, scurvy, &c.

Soap pills. Succ.

Take of hard white soap, two ounces; extract of birch, one ounce. Let them be formed into a mass, to be divided into pills, each containing three grains.

Although many virtues have been attributed to the birch, yet we are inclined to think, that it here serves little other purpose than to give the form of pills to the soap. And this article, even when taken in small quantity with some constitutions, operates as a gentle laxative. But besides this, it has also been supposed to be highly useful both in cases of jaundice and of calculus. There can, however, be little doubt, that the theories on which it has been inferred that it may be useful in such complaints are not well founded; and we may perhaps add, that the use of it, even to a great extent, is by no means attended with those consequences which were once alleged to arise from it.

Storax pills. Succ.

Take of strained storax, five scruples; extract of liquorice, three drams; opium, one dram. Let the opium, dissolved in wine, be added to the other ingredients, so as to form a mass of proper consistence, to be made into pills, each weighing three grains.

These pills are principally active in consequence of the opium which they contain. And they are chiefly meant with a view to a slow solution in the stomach, and consequently producing more gradual and lasting effects. One grain of opium is contained in seventeen grains of the mass.

CHAP. XVIII. *Electuaries.*

ELECTUARIES are composed chiefly of powders mixed up with syrups, &c. into such a consistence that

the powders may not separate in keeping, that a dose may be easily taken upon the point of a knife, and not prove too stiff to swallow.

Electuaries receive chiefly the milder alterative medicines, and such as are not ungrateful to the palate. The more powerful drugs, as cathartics, emetics, opiates, and the like (except in officinal electuaries to be dispensed by weight), are seldom trusted in this form, on account of the uncertainty of the dose; disgustful ones, acrids, bitters, fetids, cannot be conveniently taken in it; nor is the form of an electuary well fitted for the more ponderous substances, as mercurials, these being apt to subside in keeping, unless the composition be made very stiff.

The lighter powders require thrice their weight of honey, or syrup boiled to the thickness of honey, to make them into the consistence of an electuary; of syrups of the common consistence, twice the weight of the powder is sufficient.

Where the common syrups are employed, it is necessary to add likewise a little conserve, to prevent the compound from drying too soon; electuaries of Peruvian bark, for instance, made up with syrup alone, will often in a day or two grow too dry for taking.

Some powders, especially those of the less grateful kind, are more conveniently made up with mucilage than with syrup, honey, or conserve. The three latter stick about the mouth and fauces, and thus occasion the taste of the medicine to remain for a considerable time; while mucilages pass freely, without leaving any taste in the mouth. A little soft extract of liquorice, joined to the mucilage, renders the composition sufficiently grateful, without the inconveniences of the more adhesive sweets.

The quantity of an electuary, directed at a time, in extemporaneous prescription, varies much according to its constituent parts, but it is rarely less than the size of a nutmeg, or more than two or three ounces.

General rules for making electuaries.

- I. The rules already laid down for decoctions and powders in general, are likewise to be observed in making decoctions and powders for electuaries.
- II. Gums, inspissated juices, and such other substances as are not pulverizable, should be dissolved in the liquor prescribed: then add the powders by little and little, and keep the whole briskly stirring, so as to make an equable and uniform mixture.
- III. Astringent electuaries, and such as have pulps of fruit in their composition, should be prepared only in small quantities at a time: for astringent medicines lose much of their virtue in being kept in this form, and the pulps of fruits are apt to become sour.
- IV. The superfluous moisture of the pulps should be exhale over a gentle fire, before the other ingredients are added to them.
- V. Electuaries, if they grow dry in keeping, are to be reduced to a due consistence, with the addition of a little canary wine, and not with syrup or honey: by this means the dose will be the least uncertain; a circumstance deserving particular regard, in those especially which are made up with syrup, and contain a proportion of opium.

Electuary of cassia. L.

Take of the flesh extracted pulp of cassia, half a pound; manna, two ounces; pulp of tamarinds, one ounce; rose-syrup, half a pound. Beat the manna, and dissolve it over a slow fire in the rose-syrup; then add the pulps; and with a continued heat evaporate the whole to the proper thickness of an electuary.

Electuary of cassia, commonly called diacassia. E.

Take of pulp of cassia fistularis, six ounces; pulp of tamarinds, manna, each an ounce and a half; syrup of pale roses, six ounces. Having beat the manna in a mortar, dissolve it with a gentle heat in the syrup; then add the pulps, and evaporate them with a regularly continued heat to the consistence of an electuary.

These compositions are very convenient officinals, to serve as a basis for purgative electuaries and other similar purposes; as the pulping a small quantity of the fruits, for extemporaneous prescription, is very troublesome. The tamarinds give them a pleasant taste, and do not subject them, as might be expected, to turn sour. After standing for four months, the composition has been found no sourer than when first made. This electuary is likewise usefully taken by itself, to the quantity of two or three drams occasionally, for gently loosening the belly in costive habits.

Electuary of scammony. L.

Take of scammony, in powder, one ounce and an half; cloves, ginger, of each six drams; essential oil of caraway, half a dram; syrup of roses, as much as is sufficient. Mix the spices, powdered together, with the syrup; then add the scammony, and lastly the oil of caraway.

This electuary is a warm brisk purgative. It is a reform of the *electuarium caryocostinum* of our preceding dispensatories; a composition which was greatly complained of, as being inconvenient to take on account of the largeness of its dose. A dram and a half of this, which contains fifteen grains of scammony, is equivalent to half an ounce of the other.

Electuary of fenna. L.

Take of fenna, eight ounces; figs, one pound; pulp of tamarinds, or cassia, of prunes, each half a pound; coriander seeds, four ounces; liquorice, three ounces; double-refined sugar, two pounds and an half. Powder the fenna with the coriander seeds, and sift out ten ounces of the mixed powder. Boil the remainder with the figs and liquorice, in four pints of distilled water, to one half; then press out and strain the liquor. Evaporate this strained liquor to the weight of about a pound and an half; then add the sugar, and make a syrup; add this syrup by degrees to the pulps, and lastly mix in the powder.

Lentive electuary. E.

Take of pulp of French prunes, one pound; pulp of cassia, pulp of tamarinds, each two ounces and a half; black syrup of sugar, commonly called *mollasses*, one pound and a half; fenna leaves, in fine powder,

four ounces; coriander seeds, in fine powder, half an ounce. Having boiled the pulps with the syrup to the consistence of honey, add the powders, and beat the whole into an electuary.

This electuary, the name of which is with propriety changed by the London college, is now freed from some superfluous ingredients which were left in it at former revivals, *viz.* polypody root, French mercury leaves, fenugreek seeds, and linseed. Mollasses is preferable to either honey or sugar, as it coincides with the intention, and is not only of itself inapt to ferment, but likewise prevents such substances as are this way disposed from running into fermentation.

It is a very convenient laxative, and has long been in common use among practitioners. Taken to the quantity of a nutmeg or more, as occasion may require, it is an excellent laxative for loosening the belly in costive habits.

Japonic electuary, commonly called *Japonic confection*. E.

- 594 Take of Japan earth, four ounces; gum-kino, three ounces; cinnamon, nutmeg, each one ounce; opium dissolved in a sufficient quantity of Spanish white wine, one dram and a half; syrup of dried roses, boiled to the consistence of honey, two pounds and a quarter. Mix and form them into an electuary.

The ingredients in this electuary seem extremely well chosen, and are so proportioned to one another, that the quantity of opium is the same as in the diascordium of the former pharmacopœias of Edinburgh, *viz.* one grain in ten scruples. The gum-kino, now substituted for the tormentil root, is an excellent improvement in the formula.

Tin electuary. Brun.

- 595 Take of pure tin, quicksilver, each one ounce. Let them be formed into an amalgam; oyster shells, prepared one ounce. Reduce the whole to a powder. Take of this powder, conserve of wormwood, each one ounce, and form an electuary with syrup of mint.

Tin, as we have already had occasion to observe above (n° 312.), has long been celebrated for the expulsion of tœnia; and it is also well known, that in mercury we have one of the most powerful anthelmintics. Such a combination as the present, then, might be supposed well suited for the removal of that animal from the alimentary canal; and accordingly it has been alleged, that this electuary has sometimes succeeded after other remedies have failed. It may be taken twice a day, to the extent of two or three drams for a dose.

Electuary for the gums. Succ.

- 596 Take of powdered myrrh, three drams; cream of tartar, cochineal, each a dram and a half. Grind them together in a glass mortar; then add melted honey, four ounces; cloves, in powder, one dram.

Myrrh, particularly under the form of tincture, has long been a favourite application to the gums, when in a spongy or ulcerated state. But the spirituous menstruum there employed, although sometimes favouring the intention in view, in other instances occurs as an objection to its use. In these cases, the benefit to be

derived from the myrrh may be obtained from this electuary, which may always be applied with safety, and sometimes with advantage.

Electuary of manna. Succ.

- Take of manna, refined sugar pounded, fennel-water, each two ounces. Strain the mixture, using expression; then add fine powder of the root of the retentive orris, one dram; fresh drawn almond oil, one ounce.

In this electuary we have a gently emollient laxative, which is very useful in those cases where obstipation either arises from indurated feces, or is supported by that cause. But its cathartic powers are by no means considerable.

Nitrous electuary. Gen.

- Take of purified nitre, half an ounce; conserve of roses, four ounces. Mix them.

Under this formula nitre may be introduced to a considerable extent, without giving uneasiness at the stomach, while at the same time the refrigerant power is combined with the astringency of the roses. From these circumstances it may be advantageously employed in different cases, but particularly in instances of hæmoptysis.

Terbinthinate electuary. Succ.

- Take of spirit of turpentine, half an ounce; honey, one ounce; powder of liquorice, as much as is sufficient for the formation of an electuary.

Under this form, the oil of turpentine may be introduced with less uneasiness than perhaps under almost any other. And it may thus be employed for different purposes, but particularly with a view to its diuretic power. But it has been especially celebrated for the cure of obstinate rheumatism, and above all, for that modification of rheumatism which has the name of *ispelias*, and which is found in many instances obstinately to resist other modes of cure.

Lentil linctus. Succ.

- Take of gum-arabic, bruised, two drams; cherry-water, half an ounce. By trituration in a mortar, mix with them almond oil, fresh drawn, syrup of almonds, each seven ounces.

In this we have a very agreeable emollient linctus, highly useful in recent catarrhal affections, for lubricating the throat and fauces. It may be taken at pleasure to any extent that the stomach may easily bear.

CHAP. XXIX. *Confections*.

ALTHOUGH the London college have separated these from electuaries, yet they differ so little, that in most pharmacopœias they are ranked under the same head. And in that of Edinburgh, there are several articles which have promiscuously the name either of *confection* or *electuary*. But as no inconvenience arises from the separation, and as we have followed the order of the London pharmacopœia in other particulars, it would be improper to deviate from it in this.

Aromatic confectio. L.

Take of zedoary, in coarse powder, fassion, of each half a pound; distilled water, three pints. Macerate for twenty-four hours; then press and strain. Reduce the strained liquor, by evaporation, to a pint and a half, to which add the following, rubbed to a very fine powder; compound powder of crabs-claws, sixteen ounces; cinnamon, nutmegs, of each two ounces; cloves, one ounce; smaller cardamom-seeds, hulled, half an ounce; double-refined sugar, two pounds. Make a confectio.

This confectio is composed of the more unexceptionable ingredients of a composition formerly held in great esteem, and which was called, from its author, *confectio, Rulighana*. The original confectio was composed of no less than five and twenty particulars; each of which were examined apart, except one, moor-grass, the flower of which is too small to be gathered in sufficient quantity for the general use of the medicine, and the plant is possessed of hurtful qualities, as is experienced in cattle that feed where it grows. In this examination, many of the extracts came out so very nauseous, that it was impossible to retain them, consistent with any regard to the taste of the composition. But some few, of equal efficacy with any of the rest, being of a tolerable taste and flavour, were compounded in different proportions; and when, after many trials, a composition was approved, the quantity of each material, that would yield the proportion of extract which entered that composition, was calculated, and from thence the proportions were collected as now set down: after which the compound extract was made, and found to answer expectation. The London college, in the present edition of their pharmacopeia, have still further simplified this formula, by rejecting the rosemary, juniper, and cardamoms, which formerly entered it.

The confectio, as now reformed, is a sufficiently grateful and moderately warm cordial; and frequently given with that intention, from eight or ten grains to a scruple or upwards, in boluses or draughts. The formula might perhaps be still more simplified without any loss. The crabs claw powder does not appear to be very necessary, and is inserted rather in compliance with the original formula, than from its contributing any thing to the intention of the medicine; and the following formula of the Edinburgh pharmacopeia seems to be preferable to that of the London, even in its present improved state.

Confectio Terebinthy, commonly called *cordial confectio. E.*

Take of conserve of orange-peel, three ounces; preserved nutmegs, an ounce and a half; preserved ginger, six drams; cinnamon, in fine powder, half an ounce; syrup of orange peel, as much as will form the whole into an electuary.

In the above simple and elegant formula, a number of milder ingredients are rejected, and those substituted in their place are medicines of approved efficacy. We therefore consider this preparation as an useful remedy for the purposes expressed in its title.

Confectio of opium. L.

Take of hard purified opium, powdered, six drams;

long pepper, ginger, caraway-seeds, of each two ounces; syrup of white poppy, boiled to the consistence of honey, three times the weight of the whole. Mix the purified opium carefully with syrup gently heated; then add the rest, rubbed to powder.

Thebaic electuary. E.

Take of aromatic powder, six ounces; Virginian snake-root, in fine powder, three ounces; opium dissolved in a sufficient quantity of Spanish white wine, three drams; clarified honey, thrice the weight of the powders. Mix them, and form an electuary.

These compositions consist of very powerful ingredients, and are doubtless capable of answering every end that can be reasonably expected from the more voluminous *Thebaica* of Andromachus. The London college also had formerly their *Thebaica* composed of the less exceptionable ingredients of Andromachus's. But as these medicines have for a long time been chiefly employed for external purposes, by the way of cataplasm, the London *theriaca* is now omitted, and its place supplied by a cataplasm composed of a few well-chosen articles, under the name of *cataplasm of cummin*; of which hereafter. For internal use, none of the *theriacas* are at present so much regarded as they have been heretofore; practitioners having introduced in their room extemporaneous boluses of Virginian snake-root, camphor, contrayerva, and the like; which answer all their intentions, with this advantage, that they may be given either with or without opium; an ingredient which renders the others prejudicial in cases where they might otherwise be proper.

With regard to the quantity of opium in the foregoing compositions, one grain thereof is contained in thirty-six grains of the confectio of opium, and in five scruples of the thebaic electuary. The proportion of opium will vary a little, according to the time that they have been kept: their moisture by degrees exhaling, so as to leave the remainder stronger of the opium than an equal weight was at first. A change of this kind is taken notice of by many writers, but falsely attributed to an imaginary fermentive quality of the ingredients; by which they were supposed, from their multiplicity and contrariety, to be continually exalting and improving the virtues of each other.

A good deal of care is requisite in making these compositions, to prevent the waste which is apt to happen in the pounding, and which would render the proportion of opium to the other ingredients precarious. The intention of dissolving the opium in wine, for these and other electuaries, is, that it may be more uniformly mixed with the rest.

These compositions fully supply the place of two articles, which, though long banished from the shops, we shall here subjoin, as examples of the amazing height to which composition in medicine had at one time proceeded.

Mithridate, or the *confectio of Democrates*.

Take of cinnamon, fourteen drams; myrrh, eleven drams; agaric, Indian nard, ginger, saffron, seeds of mithridate mustard, frankincense, clove turpentine, each ten drams; camels hay, colts, or in its stead zedoary, Indian leaf, or in its stead mace, Rechas long

long pepper, hartwort seeds, hypocistis, storax strained, opopanax, galbanum strained, opobalsam, or in its stead expressed oil of nutmegs, Russian castor, each one ounce; Poley mountain, scordium, carpobalsam, or in its stead cubebs, white pepper, candy-carrot seed, bdellium strained, each seven drams; Celtic nard, gentian root, dittany of Crete, red roses, Macedonian parsley seed, lesser cardamom seeds husked, sweet fennel seed, gum arabic, opium strained, each five drams; calamus aromaticus, wild valerian root, aniseed, sagapenum strained, each three drams; meum athamanticum, St John's wort, acacia, or in its stead terra Japonica, bellies of skinks, each two drams and a half; clarified honey, thrice the weight of all the other ingredients. Warm the honey, and mix with it the opium dissolved in wine; melt the storax, galbanum, turpentine, and opobalsam (or expressed oil of nutmegs), together in another vessel, continually stirring them about, to prevent their burning; with these so melted, mix the hot honey, at first by spoonfuls, and afterwards in larger quantities at a time; when the whole is grown almost cold, add by degrees the other spices reduced into powder.

Theriaca of Andromachus, Venice treacle.

Take of troches of squills, half a pound; long pepper, opium strained, vipers dried, each three ounces; cinnamon, opobalsam, or in its stead expressed oil of nutmegs, each two ounces; agaric, Florence orris root, scordium, red roses, navew seeds, extract of liquorice, each an ounce and a half; Indian nard, saffron, anionum, myrrh, costus, or in its stead zedoary, camel's lay, each one ounce; cinquefoil root, rhubarb, ginger, Indian leaf, or in its stead mace, dittany of Crete, horehound leaves, calamint leaves, stechas, black pepper, Macedonian parsley seed, olibanum, chio turpentine, wild valerian root, each six drams; gentian root, Celtic nard, spignel, leaves of Poley mountain, of St John's wort, and of groundpine, germander tops with the seed, carpobalsam, or in its stead cubebs, aniseed, sweet fennel seed, lesser cardamom seeds, husked, seeds of bishop's weed, of hartwort, and of treacle mustard, hypocistis, acacia, or in its stead Japan earth, gum arabic, storax strained, sagapenum strained, terra Lemnia, or in its stead bole armenic, or French bole, green vitriol calcined, each half an ounce; small (or in its stead the long) birthwort root, lesser century tops, candy-carrot seed, opopanax, galbanum, strained, Russian castor, Jews pitch, or in its stead white amber prepared, calamus aromaticus, each two drams; clarified honey, thrice the weight of all the other ingredients. Let these ingredients be mixed together, after the same manner as directed in making the mithridate.

These celebrated electuaries are often mentioned by medical writers, and may serve as examples of the wild exuberance of composition which the superstition of former ages brought into vogue. The theriaca is a formation of mithridate made by Andromachus physician to Nero. The mithridate itself is said to have been found in the cabinet of Mithridates king of Pontus. The first publishers of this pompous arcanum were very extravagant in their commendations of its

virtues; the principal of which was made to consist in its being a most powerful preservative against all kinds of venom; whoever took a proper quantity in the morning was insured from being poisoned during that whole day. This was confirmed by the example of its supposed inventor, who, as Celsus informs us, was by its constant use so fortified against the commonly reputed poisons, that none of them would have any effect upon him when he wanted their assistance. But the notions of poisons which prevailed in those ruder ages, were manifestly erroneous. Before experience had furnished mankind with a competent knowledge of the powers of simples, they were under perpetual alarms from an apprehension of poisons, and busied themselves in contriving compositions which should counteract their effects, accumulating together all those substances which they imagined to be possessed of any degree of alexipharmic power. Hence proceed the voluminous antidotes which we meet with in the writings of the ancient physician; yet it does not appear that they were acquainted with any real poison except the cicuta, aconitum, and bites of venomous animals; and for these they knew of no antidote whatever. Even admitting the reality of the poisons, and the efficacy of the several antidotes separately, the compositions could no more answer the purposes expected from them, than the accumulating of all the medicinal simples into one form could make a remedy against all diseases.

Yet notwithstanding the absurdity in the original intention of these medicines, and their enormity in point of composition, as they contain several powerful materials, whose virtues, though greatly prejudiced, yet are not destroyed, by their multiplicity and contrariety; the compounds have been found, from repeated experience, to produce very considerable effects as warm opiate diaphoretics.

These compositions might without doubt be leapt of numerous superfluities without any diminution of their virtues; yet as the effects of them, in their present form, are so well known, so much regard has been paid to ancient authority as not to attempt a reformation of that kind. Although these forms were originally complex, yet subsequent additions had crept into them. Neither the description in verse of the elder Andromachus, nor the prose explanation of the younger, make any mention of the white pepper afterwards added to the theriaca; and the orris root, in the mithridate of our former pharmacopias, is also a supernumerary ingredient, not warranted by the original: these therefore are rejected. Nor is the asarum in the mithridate grounded on any good authority: the verse it is taken from is mutilated and corrupt; and the word which some, on conjecture only, suppose to have been asarum, others, also on conjecture, chouse to read differently. Till some emendation shall be better founded than merely on critical guesses, this single species may be safely passed over without any prejudice to the medicine. One of the ancient descriptions afford any other light in this particular: for they either omit this ingredient, and others also, or abound with additions.

Another innovation on both these medicines also took place. In each of these compositions were used both cinnamon and cassia lignea; and it is very evident, from

from several parts of Galen's works, that the latter was used by the ancients only on account of the great difficulty of procuring the other; so that to retain the cassia, now that cinnamon is so common, is a blind following of these writers, without any attention to their meaning: the cassia therefore is now rejected, and half the quantity of cinnamon put in its room; which is the proportion that Galen directs to be observed in substituting the one for the other. It is probable that the case is the same with regard to the Celtic and the Indian nard; that the first had a place in these compositions on account of the difficulty of procuring the Indian, for Galen expressly prefers the latter.

There is a material error in regard to the theriaca, which has passed through several editions of our pharmacopœia: this is the substituting the Roman vitriol for the ancient chalcitis, now not certainly known; and, in the catalogue of simples, describing the Roman to be a blue vitriol whereas the Italian writers are unanimous it is a green vitriol; and were it not, it would not answer to the effects of the chalcitis, which was certainly a chalybeate, and gives the medicine its black colour. What has chiefly occasioned chalcitis to be supposed a cupreous vitriol seems to be its name, derived from χαλκός, *copper*: but it is to be observed that all vitriols were formerly imagined to proceed from copper, and were named accordingly: the green or martial vitriols are still called by the Germans *kupffer wasser*, and by us *copperas*. It is probable that the ancient chalcitis was no other than a native martial vitriol, calcined by the heat of those warm climates to a degree of yellowish red or coppery colour; and therefore the common green vitriol, thus calcined by art, very properly supplies its place.

The preparation of these medicines has been somewhat facilitated by omitting the *trochisci cytherei* used in the mithridate, and the *bodichroi* and *viperini* for the theriaca; and inserting their ingredients, after Zwelfer's manner, in the compositions they are intended for. This is done in the theriaca very commodiously; the ingredients in these troches uniting with those in the theriaca itself into unbroken numbers. But to render the numbers equally simple in the mithridate, it was necessary to retrench a few odd grains from some of the articles, and make a small addition to some others. The proportions of the ingredients in the *trochisci cytherei* are adjusted from the original description in Galen, the numbers in our former pharmacopœia being very erroneous.

Both the London and Edinburgh colleges ventured at length to discard these venerable relics. The Edinburgh college at first substituted in their room an elegant and simple form, equivalent to them both in efficacy, under the title of *theriaca Edinensis*, Edinburgh theriaca. In later editions, however, they have entirely banished the name of theriaca from their book, and have put in its place the more elegant composition already mentioned, the *thibic delectary*.

CHAP. XXX. *Medicinal Waters.*

WE have already taken notice of many articles which are either dissolved in water, or communicate their virtues to it; and in one sense of the word these

may be called *medicated waters*. Sometimes this impregnation is effected by the aid of heat, sometimes without it; and thus are formed decoctions, infusions, and the like. But among those articles referred to in this chapter, there takes place more watery solution only, and they are used solely with the intention of acting topically in the way of lotion, injection, or at the utmost of gargarism.

Compound alum-water. L.

Take of alum, vitriolated zinc, each half an ounce; boiling distilled water, two pints. Pour the water on the salts in a glass vessel, and strain.

This water was long known in our shops under the title of *aqua aluminosa Botani*.

Bates directed the salts to be first powdered and melted over the fire: but this is needless trouble, since the melting only evaporates the aqueous parts, which are restored again on the addition of the water. This liquor is used for cleansing and healing ulcers and wounds; and for removing cutaneous eruptions, the part being bathed with it hot three or four times a-day. It is sometimes likewise employed as a collisium; and as an injection in the gonorrhœa and fluor albus when not accompanied with virulence.

Styptic water. E.

Take of blue vitriol, alum, each three ounces; water, two pounds. Boil them until the salts be dissolved; then filter the liquor, and add an ounce and an half of vitriolic acid.

This water, though made with the blue in place of the white vitriol, cannot be considered as differing very much from the former. It is formed on the styptic recommended by Sydenham for stopping bleeding at the nose, and other external hemorrhages; for this purpose cloths or doills are to be dipped in the liquor, and applied to the part.

Water of ammoniated copper. L.

Take of lime-water, one pint; sal ammoniac, one dram. Let them stand together, in a copper vessel, till the ammoniac be saturated.

Sapphire-coloured water. E.

Take of lime-water, newly made, eight ounces; sal ammoniac, two scruples; verdegis, powdered, four grains. Mix them, and after 24 hours strain the liquor.

This is a much more elegant and convenient method than the preceding.

This water is at present pretty much in use as a detergent of foul and obstinate ulcers, and for taking away specks or films in the eyes. The copper contributes more to its colour than to its medicinal efficacy; for the quantity of the metal dissolved is extremely small.

Compound water of acetated litharge. L.

Take of acetated water of litharge, two drams; distilled water, two pints; proof-spirit, two drams. Mix the spirit with the acetated water of litharge; then add the distilled water.

Prepara-
tions and
Composi-
tions.

This liquor is of the same nature with solutions of sugar of lead, and is analogous to the vegeto-mineral water of Mr Goulard. It is only used externally as a cosmetic against cutaneous eruptions, redness, inflammation, &c. But even here it is alleged that it is not altogether void of danger, and that there are examples of its continued employment having occasioned sundry ill consequences. But at the same time the very frequent use that is made of it with perfect impunity would lead us to conclude that in these observations there must be some mistake.

Water of vitriolated zinc with camphor. L.

- 611 Take of vitriolated zinc, half an ounce; camphorated spirit, half an ounce; boiling water, two pints. Mix, and filter through paper.

This is an improved method of forming the vitriolic camphorated water of the former editions of the London pharmacopœia. It is used externally as a lotion for some ulcers, particularly those in which it is necessary to restrain a great discharge. It is also not unfrequently employed as a collyrium in some cases of ophthalmia, where a large discharge of watery fluid takes place from the eyes, with but little inflammation. But when it is to be applied to this tender organ, it ought, at first at least, to be diluted by the addition of more water.

Vitriolic water. E.

- 612 Take of white vitriol, sixteen grains; water, eight ounces; weak vitriolic acid, sixteen drops. Dissolve the vitriol in the water, and then adding the acid, strain through paper.

Where the eyes are watery or inflamed, this solution of white vitriol is a very useful application. The slighter inflammations will frequently yield to this medicine without any other assistance; in the more violent ones, venesection and cathartics are to be premised to its use.

CHAP. XXXI. *Plasters.*

- 613 **PLASTERS** are composed chiefly of oily and unctuous substances, united with powders into such a consistence that the compound may remain firm in the cold without sticking to the fingers; that it may be soft and pliable in a low degree of heat, and that by the warmth of the human body it be so tenacious as readily to adhere both to the part on which it is applied and to the substance on which it is spread.

There is, however, a difference in the consistence of plasters, according to the purposes they are to be applied to: thus, such as are intended for the breast and stomach should be very soft and yielding, while those designed for the limbs are made firmer and more adhesive. An ounce of expressed oil, an ounce of yellow wax, and half an ounce of any proper powder, will make a plaster of the first consistence: for a hard one, an ounce more of wax, and half an ounce more of powder, may be added. Plasters may likewise be made of resins, gummy resins, &c. without wax, especially in extemporaneous prescription: for officinals these compositions are less proper, as they soon grow too soft in keeping, and fall flat in a warm air.

It has been supposed, that plasters might be impregnated with the specific virtues of different vegetables, by boiling the recent vegetable with the oil employed for the composition of the plaster. The coction was continued till the herb was almost crisp, with care to prevent the matter from contracting a black colour: after which the liquid was strained off, and set on the fire again, till all the aqueous moisture had exhales. We have already observed, that this treatment does not communicate to the oils any very valuable qualities, even relative to their use in a fluid state: much less can plasters, made with such oils, receive any considerable efficacy from the herbs.

Calces of lead, boiled with oils, unite with them into a plaster of an excellent consistence, and which makes a proper basis for several other plasters.

In the boiling of these compositions, a quantity of water must be added, to prevent the plaster from burning and growing black. Such water, as it may be necessary to add during the boiling, must be previously made hot, for cold liquor would not only prolong the process, but likewise occasion the matter to explode, and be thrown about with violence, to the great danger of the operator: this accident will equally happen on the addition of hot water, if the plaster be extremely hot.

Ammoniacum plaster with quicksilver. L.

- 614 Take of strained ammoniacum, one pound; purified quicksilver, three ounces; sulphurated oil, one dram, or what is sufficient. Rub the quicksilver with the sulphurated oil until the globules disappear; then add, by little at a time, the melted ammoniacum, and mix them.

This is a very well contrived mercurial plaster. The ammoniacum in general affords a good basis for the application of the mercury. In some cases, however, it is not sufficiently adhesive. But this inconvenience, when it does occur, may be readily remedied by the addition of a small quantity of turpentine.

Plaster of Spanish flies. L.

- 615 Take of Spanish flies, one pound; wax plaster, two pounds; prepared hog's lard, half a pound. Having melted the plaster and lard, a little before they coagulate sprinkle in the flies, reduced to a very fine powder.

Blistering plaster, or epispastic plaster. E.

- Take of hog's lard, yellow wax, white resin, cantharides, each equal weights. Beat the cantharides into a fine powder, and add them to the other ingredients, previously melted, and removed from the fire.

Both these formulæ are very well suited to answer the intention in view, that of exciting blisters; for both are of a proper consistence, and sufficient degree of tenacity, which are here the only requisites. Cantharides of good quality, duly applied to the skin, never fail of producing blisters. When, therefore, the desired effect does not take place, it is to be ascribed to the flies either being faulty at first, or having their activity afterwards destroyed by some accidental circumstance; such as too great heat in forming, in spreading the plaster, or the like. And when due attention is paid

Prepara-
tions and
Composi-
tions.

Prepara-
tions and
Composi-
tions.

to these particulars, the simple compositions now introduced answer the purpose better than those compound plasters with mustard seed, black pepper, vinegar, verdigris, and the like, which had formerly a place in our pharmacopœias. It is not however improbable, that the pain of blistering-plasters might be considerably diminished by the addition of a portion of opium, without preventing the good effects otherwise to be derived from them.

Wax-plaster.

- 616 Take of yellow wax, prepared mutton-suet, each three pounds; yellow resin, one pound. Melt them together, and strain the mixture whilst it is fluid.

L.

Take of yellow wax, three parts; mutton-suet, white resin, two parts. Melt them together into a plaster; which supplies the place of melilot plaster.

E.

This plaster had formerly the title of *drawing-plaster*, and was chiefly employed as a dressing after blisters, to support some discharge.

It is a very well contrived plaster for that purpose. It is calculated to supply the place of melilot plaster; whose great irritation, when employed for the dressing of blisters, has been continually complained of. This was owing to the large quantity of resin it contained, which is here on that account retrenched. It would seem that, when designed only for dressing blisters, the resin ought to be entirely omitted, unless where a continuance of the pain and irritation, excited by the vesicatory, is required. Indeed plasters of any kind are not very proper for this purpose: their consistence makes them sit uneasy, and their adhesiveness renders the taking them off painful. Cerates, which are softer and less adhesive, appear much more eligible; the cerate of spermaceti will serve for general use; and for some particular purposes, the cerate of yellow resin may be applied.

Cummin-plaster. L.

- 617 Take of the seeds of cummin, seeds of caraway, bay-berries, each three ounces; Burgundy pitch, three pounds; yellow wax, three ounces. Mix, with the melted pitch and wax, the rest of the ingredients, powdered, and make a plaster.

This plaster stands recommended as a moderately warm discutient; and is directed by some to be applied to the hypogastric region, for strengthening the viscera, and expelling stultencies: but it is a matter of great doubt, whether it derives any virtue either from the article from which it is named, or from the caraway or bay-berries which enter its composition.

Rub., commonly called *antilystERIC*, plaster. E.

- 618 Take of common plaster, asphaltida, strained, each two parts; yellow wax, strained galbanum, each one part. Mix, and make them into a plaster.

This plaster is applied to the umbilical region, or over the whole abdomen, in hysterical cases; and sometimes with good effect; but probably more from its giving an additional degree of heat to the part, than from any influence derived from the fetid

gums. It has indeed been alleged that from the application of this plaster to the abdomen, the taste of asphaltida can be distinctly perceived in the mouth; and it is not improbable, that some absorption of its active parts may take place by the lymphatic vessels of the surface; while, at the same time, the asphaltida thus applied must constantly, in some degree, act on the nerves of the nose. But, in both these ways, its influence can be insensurable only; and much more effect may be obtained from a very small quantity taken internally. And we are on the whole inclined to think, that the addition of the fetid gums to the common plaster is here more disagreeable than useful.

Ladanum plaster. L.

Take of ladanum, three ounces; frankincense, one ounce; cinnamon powdered, expressed oil, called *oil of mace*, of each half an ounce; essential oil of spearmint, one dram. To the melted frankincense add first the ladanum, softened by heat; then the oil of mace. Mix these afterwards with the cinnamon and oil of mint, and beat them together in a warm mortar into a plaster. Let it be kept in a close vessel.

This has been considered as a very elegant stomach plaster. It is contrived so as to be easily made occasionally (for these kinds of compositions, on account of their volatile ingredients, are not fit for keeping), and to be but moderately adhesive, so as not to offend the skin, and that it may without difficulty be frequently taken off and renewed; which these sorts of applications, in order to their producing any considerable effect, require to be. But after all, it probably acts more from the mere covering which it gives to the stomach, than from any of the articles abounding with essential oil which it contains.

Litharge-plaster. L.

Take of litharge, in very fine powder, five pounds; olive-oil, a gallon. Boil them with a slow fire, in about two pints of water, constantly stirring until the oil and litharge unite, and have the consistence of a plaster. But it will be proper to add more boiling water, if the water that was first added be nearly consumed before the end of the process.

Common plaster. E.

Take of litharge, one part; olive-oil, two parts; boil them, adding water, and constantly stirring the mixture till the oil and litharge be formed into a plaster.

The heat in these processes should be gentle, and the matter kept constantly stirring, otherwise it swells up, and is apt to run over the vessel. If the composition proves discoloured, the addition of a little white lead and oil will improve the colour.

These plasters, which have long been known under the name of *Diachylon*, are the common application in excoriations of the skin, slight flesh wounds, and the like. They keep the part soft, and somewhat warm, and defend it from the air, which is all that can be expected in these cases from any plaster. Some

of our industrious medicine-makers have thought these purposes might be answered by a cheaper composition, and accordingly have added a large quantity of common whitening and hogs lard: this, however, is by no means allowable, not only as it does not stick so well, but likewise as the lard is apt to grow rancid and acrimonious. The counterfeit is distinguishable by the eye.

Litharge plaster with gum. L.

- 621 Take of litharge plaster, three pounds; strained galbanum, eight ounces; turpentine, ten drams; frankincense three ounces. The galbanum and turpentine being melted with a slow fire, mix with them the powdered frankincense, and afterwards the litharge-plaster melted with a very slow fire, and make a plaster.

Gum-plaster. E.

Take of common plaster, eight parts; gum-ammoniacum strained, strained galbanum, yellow wax, each one part. Make them into a plaster according to art.

Both these plasters are used as digestives and suppuratives; particularly in abscesses, after a part of the matter has been matured and discharged, for suppurating or discharging the remaining hard part; but it is very doubtful whether they derive any advantage from the gums entering their composition.

Litharge-plaster with quicksilver. L.

- 622 Take of litharge-plaster, one pound; purified quicksilver, three ounces; sulphurated oil, one dram, or what is sufficient. Make the plaster in the same manner as the ammoniacum-plaster with quicksilver.

Mercurial or blue plaster. E.

Take of olive-oil, white resin, each one part; quicksilver, three parts; common plaster, six parts. Melt the oil and resin together, and when this mixture is cold, let the quicksilver be rubbed with it till the globules disappear; then add by degrees the common plaster, melted, and let the whole be accurately mixed.

These mercurial plasters are looked on as powerful resolvents and discutients, acting with much greater certainty for these intentions than any composition of vegetable substances alone; the mercury exerting itself in a considerable degree, and being sometimes introduced into the habit in such quantity as to affect the mouth. Pains in the joints and limbs from a venereal cause, nodes, tophi, and beginning indurations of the glands, are said sometimes to yield to them.

Litharge plaster with resin. L.

- 623 Take of litharge-plaster, three pounds; yellow resin, half a pound. Mix the powdered resin, with litharge plaster, melted with a very slow fire, and make a plaster.

Sticking plaster. E.

Take of common plaster, five parts; white resin, one

part. Melt them together so as to make a plaster.

These plasters are used chiefly as adhesives for keeping on other dressings, &c.

Plaster of Burgundy pitch. L.

Take of Burgundy pitch, two pounds; ladanum, one pound; yellow resin, yellow wax, of each four ounces; the expressed oil, commonly called the oil of mace, one ounce. To the pitch, resin, and wax, melted together, add first the ladanum, and then the oil of mace.

This plaster was at one time much celebrated under the title of *cephalic plaster*, the name which it formerly held in our pharmacopœias. It was applied in weakness or pains of the head, to the temples, forehead, &c. and sometimes likewise to the feet. Schulze relates, that an inveterate rheumatism in the temples, which at times extended to the teeth, and occasioned intolerable pain, was completely cured in two days by a plaster of this kind (with the addition of a little opium) applied to the part, after many other remedies had been tried in vain. He adds, that a large quantity of liquid matter exuded under the plaster in drops, which were so acrid as to corrode the cuticle: but it is probable, that this was much more the effect of the Burgundy pitch than of any other part of the composition; for when applied to a very tender skin, it often produces even vesication, and in most instances operates as rubefacient or hot plaster: and as far as it has any good effect in headach, it is probable that its influence is to be explained on this ground.

Soap-plaster. L.

Take of soap, half a pound; litharge-plaster, three pounds; mix the soap with the melted litharge plaster, and boil them to the thickness of a plaster.

Saponaceous plaster. E.

Take of common plaster, four parts; gum-plaster, two parts; Castile soap, scraped, one part. To the plasters, melted together, add the soap; then boil for a little, so as to form a plaster.

These plasters have been supposed to derive a resolvent power from the soap; and in the last, the addition of the gums is supposed to promote the resolvent virtue of the soap: but it is a matter of great doubt, whether they derive any material advantage from either addition.

Frankincense plaster. L.

Take of frankincense, half a pound; dragon's blood, three ounces; litharge plaster two pounds. To the melted litharge-plaster add the rest, powdered.

This plaster had formerly in the London pharmacopœia the title of *strengthening plaster*, and is a reformation of the complicated and injudicious composition described in the former pharmacopœias, under the title of *Emplastrum ad herniam*. Though for the most elegant and simple, it is as effectual for that purpose as any of the medicines of this kind. If constantly worn with a proper bandage, it, in children, frequently does service; though, perhaps, not so much

Preparations and Compositions.

from any strengthening quality of the ingredients, as from its being a soft, close, and adhesive covering. It has been supposed that plasters composed of stypic medicines constrict and strengthen the part to which they are applied, but on no very just foundation; for plasters in general relax rather than constrict, the unctuous ingredients necessary in their composition counteracting and destroying the effect of the others.

Defensive or strengthening plaster. E.

- 527 Take of common plaster, twenty-four parts; white resin, six parts; yellow wax, oil olive, each three parts; colcothar of vitriol, eight parts. Grind the colcothar with the oil, and then add it to the other ingredients previously melted.

This plaster is laid round the lips of wounds and ulcers over the other dressings, for defending them from inflammation and a fluxion of humours; which, however, as Mr Sharp very justly observes, on account of their confidence, tend rather to bring on than to prevent. It is also used in weaknesses of the large muscles, as of the loins; and its effects seem to proceed from the artificial mechanical support given to the part, which may also be done by any other plaster that adheres with equal firmness.

Deadly nightshade plaster. Brun.

- 628 Take of the juice of the recent herb of belladonna, linseed oil, each nine ounces; yellow-wax, six ounces; Venice turpentine, six drams; powder of the herb of belladonna, two ounces. Let them be formed into a plaster according to art.

There can be no doubt that the belladonna, externally applied, has a very powerful influence, both on the nerves and blood vessels of the part; and thus it has very considerable effect both on the circulation and state of sensibility of the part; and when applied under the form of this plaster, especially in affections of the mamma and scrotum, it has been said to have very powerful influence in alleviating pain, in dissolving tumors, and in promoting a favourable suppuration. It has however been but little employed in this country; and we can say nothing of it from our own experience.

Corn-plaster. Dan.

- 629 Take of galbanum, dissolved in vinegar, and again inspissated, one ounce; pitch, half an ounce; diachylon, or common plaster, two drams. Let them be melted together; and then mix with them verdigris powdered, sul ammoniac, each one scruple; and make them into a plaster.

Of this plaster, as well as the former, we can say nothing from our own experience. It has been celebrated for the removal of corns, and for alleviating the pain which they occasion; and it is not improbable that it may sometimes have a good effect from the corrosive articles which it contains; but in other cases, from this very circumstance, it may tend to aggravate the pain, particularly in the first instance.

Hemlock plaster. Succ.

- 430 Take of yellow wax, half a pound; oil olive, four ounces; gum ammoniacum, half an ounce; after

they are melted together, mix with them powdered herb of hemlock, half a pound.

This corresponds very nearly with the Emplastrum de cicuta cum ammoniaco, which had formerly a place in our pharmacopœias, and was supposed to be a powerful cooler and discutient, and to be particularly serviceable against swellings of the spleen and distensions of the hypochondres. For some time past, it has been among us entirely neglected; but the high resolvent power which Dr Stoerk has discovered in hemlock, and which he found it to exert in this as well as in other forms, intitle it to further trials. The plaster appears very well contrived, and the additional ingredients well chosen for assisting the efficacy of the hemlock.

Corrosive plaster. Gen.

- Take of corrosive sublimate mercury half a dram; hog's lard, half an ounce; yellow wax, two drams. Mix them together according to art.

There can be no doubt that the muriated mercury here employed is a very powerful corrosive; and there may be some cases in which it is preferable to other articles of the tribe of caustics: but this would seem to be a very uneconomical mode of applying it, as but a very small portion of what enters the plaster can act; and even that portion must have its action much restrained by the unctuous matters with which it is combined.

Plaster of fenugreek or of mucilages. Gen.

- Take of fenugreek-seed, two ounces; linseed-oil, warm, half a pound. Infuse them according to art, and strain; then take of yellow wax, two pounds and an half; gum ammoniac, strained, six ounces; turpentine two ounces. Melt the gum-ammoniac with the turpentine, and by degrees add the oil and wax, melted in another vessel, so as to form a plaster.

This plaster had formerly a place in our pharmacopœias, but was rejected; and although still held in esteem by some, it is probably of no great value; at least it would seem to derive but little either from the fenugreek seed, with which it is now made, or from the oil and mucilages which formerly entered into its composition.

Hemlane plaster. Succ.

- This is directed to be prepared in the same manner as the emplastrum e conio, or hemlock-plaster.

From the well-known sedative power of this plant, as affecting the nervous energy of the part to which it is applied, we might reasonably conclude that good effects might be obtained from it when used under the form of plaster: and accordingly it has been with advantage employed in this manner, for allaying pain, and resolving swelling, in cases of scirrhus and cancer.

Pitch plaster. Roll.

- Take of white resin, six ounces; ship-pitch, seven ounces; yellow wax, five ounces. Melt them and form them into a plaster.

Pitch, applied externally, has been supposed to act on two principles, by its warmth and by its adhesive quality,

Preparations and Compositions.

631

632

633

634

Preparations and Compositions.

quality. In the former way it may have some effect; but it has much more influence in the latter; and particularly it has thus been found to produce a cure in cases of tinea capitis. When a pitch plaster is applied to the affected part of the hairy scalp, and allowed to remain there for a few days, it becomes so attached to the parts, that it cannot be removed without bringing with it the bulbs of the hair in which the disease is seated: and by this means a radical cure is not unfrequently obtained, after every other remedy has been tried in vain. But the cure is a painful one, and not without danger: for in some instances, inflammations, even of an alarming nature, have been excited by the injury thus done to the parts. Hence this mode of cure is rarely had recourse to till others have been tried without effect; and when it is employed, if the disease be extensive, prudent practitioners direct its application only to a small portion at a time, the size of a crown piece or so: and after one part is fully cured, by application to another in succession, the affection may be soon completely overcome. With this intention it is most common to employ the pitch in its pure state: but the plaster here directed, while it is no less adhesive, is more manageable and flexible.

CHAP. XXXII. *Ointments and Liniments.*

635 OINTMENTS and liniments differ from plasters little otherwise than in consistence. Any of the officinal plasters, diluted with so much oil as will reduce it to the thickness of stiff honey, forms an ointment: by further increasing the oil, it becomes a liniment.

In making these preparations, the Edinburgh college direct, that fat and resinous substances are to be melted with a gentle heat; then to be constantly stirred, sprinkling in at the same time the dry ingredients, if any such are ordered, in the form of a very fine powder, till the mixture on diminishing the heat becomes stiff.

It is to be understood that the above general directions are meant to apply to each particular composition contained in the present edition of the Edinburgh pharmacopœia. It is also to be observed, that where any compositions are ordered, as bases or ingredients of others, the college always refer to those made according to their own formula.

Ointment of hog's lard. L.

436 Take of prepared hog's lard, two pounds; rose water, three ounces. Beat the lard with the rose-water until they be mixed; then melt the mixture with a slow fire, and set it apart that the water may subside; after which pour off the lard from the water, constantly stirring until it be cold:

In the last edition of London pharmacopœia, this was styled *Unguentum simplex*, the name given by the Edinburgh college to the following.

Simple ointment. E.

Take of olive oil, five parts; white wax, two parts.

Both these ointments may be used for softening the skin and healing chaps. The last is, however, preferable, on account of its being of one uniform, con-

sistence. For the same reason it is also to be preferred as the basis of other more compounded ointments.

Ointment of verdegris. E.

Take of basilicon ointment, fifteen parts; verdegris, one part.

This ointment is used for cleansing sores, and keeping down fungous flesh. Where ulcers continue to run from a weakness in the vessels of the part, the tonic powers of copper promise considerable advantage.

It is also frequently used with advantage in cases of ophthalmia, depending on scrofula, where the palpebræ are principally affected, but when it is to be thus applied it is in general requisite that it should be somewhat weakened by the addition of a proportion of simple ointment or hog's lard. An ointment similar to the above, and celebrated for the cure of such instances of ophthalmia, has long been sold under the name of *Smellon's eye-salve*.

Ointment of the white calx of quicksilver. L.

Take of the white calx of quicksilver, one dram; ointment of hog's lard, one ounce and a half. Mix, and make an ointment.

This is a very elegant mercurial ointment, and frequently used in the cure of obstinate and cutaneous affections. It is an improvement of the ointment of precipitated mercury of the last London pharmacopœia; the precipitated sulphur being thrown out of the composition, and the quantity of mercury increased.

Ointment of calx of zinc. E.

Take of simple liniment, six parts; calx of zinc, one part.

This ointment is chiefly used in affections of the eyes, particularly in those cases where redness arises rather from relaxation than from active inflammation.

Ointment of Spanish flies. L.

Take of Spanish flies, powdered, two ounces; distilled water eight ounces; ointment of yellow resin, eight ounces. Boil the water with the Spanish flies, to one half, and strain. To the strained liquor add the ointment of yellow resin. Evaporate this mixture in a water-bath, saturated with sea-salt, to the thickness of an ointment.

Epispastic ointment from infusion of cantharides. E.

Take of cantharides, white resin, yellow wax, each one ounce; hog's lard, Venice turpentine, each two ounces; boiling water, four ounces. Infuse the cantharides in the water, in a close vessel, for a night; then strongly press out and strain the liquor, and boil it with the lard till the water be consumed; then add the resin, wax, and turpentine, and make the whole into an ointment.

These ointments, containing the soluble parts of the cantharides uniformly blended with the other ingredients, are more commodious, in general occasion less pain, and are no less effectual in some cases, than the compositions with the fly in substance. This, however,

Preparations and Compositions.

637

638

639

640

Preparations and Compositions.

does not uniformly hold; and accordingly the Edinburgh college, with propriety, still retain an ointment containing the flies in substance.

Epispastic ointment, from powder of cantharides. E.

- 641 Take of basilicum ointment, seven parts; powdered cantharides, one part.

This ointment is employed in the dressings for blisters, intended to be made *perpetual*, as they are called, or to be kept running for a considerable time, which in many chronic, and some acute cases, is of great service. Particular care should be taken, that the cantharides employed in these compositions be reduced to a very fine powder, and that the mixture be made as equal and uniform as possible. But with these precautions, there are some particular habits in which this ointment operates with even less pain than the former, while at the same time it is generally more effectual.

Wax ointment. L.

- 642 Take of white wax, four ounces; spermaceti, three ounces; olive-oil, one pint. Stir them, after being melted with a slow fire, constantly and briskly, until cold.

This ointment had formerly the title of *unguentum cœcum* in the London pharmacopœia. It differs very little from the simple ointment of the Edinburgh pharmacopœia, and in nothing from the ointment of spermaceti of the London pharmacopœia, excepting that in this ointment the proportion of spermaceti is somewhat less. It is an useful cooling ointment for excoriations and other frettings of the skin.

Ointment of acetated ceruse. L.

- 643 Take of acetated ceruse, two drams; white wax, two ounces; olive-oil, half a pint. Rub the acetated ceruse, previously powdered, with some part of the olive oil; then add it to the wax, melted with the remaining oil. Stir the mixture until it be cold.

Saturnine ointment. E.

Take of simple ointment, twenty parts; sugar of lead, one part.

Both these ointments are useful coolers and desiccatives; much superior both in elegance and efficacy to the *nutritum* or *tripharmaçum*, at one time very much celebrated.

Ointment of ceruse, commonly called white ointment. E.

- 644 Take of simple ointment, five parts; ceruse, one part.

This is an useful, cooling emollient ointment, of great service in excoriations and other similar frettings of the skin. The ceruse has been objected to by some, on a supposition that it might produce some ill effects, when applied, as these unguents frequently are, to the tender bodies of children. Though there does not seem to be much danger in this external use of ceruse, the addition of it is the less necessary here, as we have another ointment containing a more active preparation of the same metal, the saturnine ointment just mentioned; which may be occasionally mixed with this, or employed by itself, in cases where saturnine applications are wanted.

Ointment of elemi. L.

Take of elemi, one pound; turpentine, ten ounces; mutton-suet, prepared, two pounds; olive-oil, two ounces. Melt the elemi with the suet; and having removed it from the fire, mix it immediately with the turpentine and oil, after which strain the mixture.

This ointment, perhaps best known by the name of *linimentum orci* has long been in use for digesting cleansing, and incarnating; and for these purposes is preferred by some to all the other compositions of this kind.

These however, are much more processes of nature than of art: and it is much to be doubted whether it has in reality any influence.

Ointment of white hellebore. L.

Take of the root of white hellebore, powdered, one ounce; ointment of hog's lard, four ounces; essence of lemons, half a scruple. Mix them, and make an ointment.

White hellebore externally applied has long been celebrated in the cure of cutaneous affections; and this is perhaps one of the best formulæ under which it can be applied, the hog's lard ointment serving as an excellent basis for it, while the essence of lemons communicates to it a very agreeable smell.

Stronger ointment of quicksilver. L.

Take of purified quicksilver, two pounds; hog's lard, prepared, twenty-three ounces; mutton-suet, prepared, one ounce. First rub the quicksilver with the suet and a little of the hog's lard, until the globules disappear; then add what remains of the lard, and make an ointment.

Weaker ointment of quicksilver. L.

Take of the stronger ointment of quicksilver, one part; hog's lard, prepared, two parts. Mix them.

Quicksilver or blue ointment. E.

Take of quicksilver, mutton suet, each one part; hog's lard, three parts. Rub them carefully in a mortar till the globules entirely disappear.

This ointment may also be made with double or triple the quantity of quicksilver.

These ointments are principally employed, not with a view to their topical action, but with the intention of introducing mercury in an active state into the circulating system. And this may be effected by gentle friction on the sound skin of any part, particularly on the inside of the thighs or legs. For this purpose, these simple ointments are much better suited than the more compounded ones with turpentine and the like, formerly employed. For by any acrid substance topical inflammation is apt to be excited, preventing further friction, and giving much uneasiness. To avoid this it is necessary, even with the mildest and weakest ointment, somewhat to change the place at which the friction is performed. But by these ointments properly managed, mercury may in some instances be as advantageously introduced, either for eradicating syph-
lis

Preparations and Compositions.

645

646

647

Prepara-
tions and
Composi-
tions.

lis, or combating other obstinate diseases as under any form whatever. But to obtain these effects, it is requisite that the ointment should be prepared with very great care; for upon the degree of triture which has been employed, the activity of the mercury must entirely depend. The addition of the mutton-fat, now adopted by both colleges, as an advantage to the ointment, as it prevents it from running into the state of oil, which the hog's lard alone in warm weather, or in a warm chamber, is sometimes apt to do, and which is followed by a separation of parts. We are even inclined to think, that the proportion of fuet directed by the London college is too small for this purpose, and indeed seems to be principally intended for the more effectual triture of the mercury: But it is much more to be regretted, that, in a medicine of activity, the two colleges should not have directed the same proportion of mercury to the fatty matter. For although both have directed ointments of different strength, neither the weakest nor the strongest agree in the proportion of mercury which they contain.

Ointment of nitrated quicksilver.

648 Take of purified quicksilver, one ounce; nitrous acid, two ounces; hog's lard, prepared, one pound. Dissolve the quicksilver in the nitrous acid; and, while it is yet hot, mix it with the hog's lard, previously melted, and just growing cold.

Yellow ointment. E.

Take of quicksilver, one ounce; spirit of nitre, two ounces; hog's lard, one pound. Dissolve the quicksilver in the spirit of nitre, by digestion in a sand-heat: and, while the solution is very hot, mix with it the lard, previously melted by itself, and just beginning to grow stiff. Stir them briskly together, in a marble mortar, so as to form the whole into an ointment.

These ointments differ only in name; and that employed by the London college is certainly the preferable appellation: For here the quicksilver, previous to its union with the lard, is brought to a saline state by means of the nitrous acid. And although its activity be very considerably moderated by the animal fat with which it is afterwards united, yet it still affords us a very active ointment; and as such it is frequently employed with success in cutaneous and other topical affections. In this condition, however, the mercury does not so readily enter the system as in the preceding form. Hence it may even be employed in some cases with more freedom; but in other instances it is apt to excoriate and inflame the parts. On this account a reduction of its strength is sometimes requisite; and it is often also necessary, from the hard consistence which it acquires, in consequence of the action of acid on the lard.

Tar ointment.

649 Take of tar, mutton fuet prepared, each half a pound. Melt them together and strain. L.
Take of tar, five parts; yellow wax two parts. E.
These compositions, though the one be formed into an ointment by means of fuet, the other by wax, can-

not be considered as differing essentially from each other. As far as they have any peculiar activity, this entirely depends on the tar. And this article, from the empyreumatic oil and saline matters which it contains, is undoubtedly, as well as turpentine, of fine activity. Accordingly, it has been successfully employed against some cutaneous affections, particularly those of domestic animals. At one time, as well as the black basilicon, it was a good deal employed as a dressing even for recent wounds. But although it still retains a place in our pharmacopœias, it is at present little used with any intention.

Ointment of yellow resin. L.

Take of yellow resin, yellow wax, each one pound; olive oil, one pint. Melt the resin and wax with a slow fire: then add the oil, and strain the mixture while hot.

Basilicon ointment. E.

Take of hog's lard, eight parts; white resin, five parts; yellow wax, two parts.

These are commonly employed in dressings, for digesting, cleansing, and incarnating wounds and ulcers. They differ very little, if at all, in their effects, from the *linimentum arcaei*, or ointment of elemi, as it is now more properly styled. But it is probable that no great effect is to be attributed to either: For there can be no doubt that the suppurative and adhesive inflammations are processes of nature, which will occur without the aid of any ointment.

Elder ointment. L.

Take of elder flowers, four pounds; mutton-fat, prepared, three pounds; olive-oil, one pint. Boil the flowers in the fuet and oil, first melted together, till they be almost crisp; then strain with expression.

This ointment does not seem superior to some others, which are much neater, and less expensive. It can scarcely be supposed to receive any considerable virtue from the ingredient from which it takes its name. And accordingly it is not without propriety that it is rejected from the pharmacopœia of the Edinburgh college.

Ointment of spermaceti. L.

Take of spermaceti, six drams; white wax, two drams; olive-oil, three ounces. Melt them together over a slow fire, stirring them constantly and briskly until they be cold.

This had formerly the name of *colbite liniment*, and it is perhaps only in consistence that it can be considered as differing from the simple ointment already mentioned, or the simple cerate afterwards to be noticed.

Sulphur ointment. L.

Take of ointment of hog's lard, half a pound; flowers of sulphur, four ounces. Mix them, and make an ointment.

Ointment of sulphur, or antiphlogistic ointment. E.

Take of hogs lard, four parts; sulphur, beat into a very

Prepara-
tions and
Composi-
tions.

650

651

652

653

very fine powder, one part. To each pound of this ointment add essence of lemons, or oil of lavender, half a dram.

Sulphur is a certain remedy for the itch, and safer than mercury. Sir John Pringle observes, that unless a mercurial unction was to touch every part of the skin, there can be no certainty of success: whereas from a sulphureous one, a cure may be obtained by only partial unctiō; the animalcula, which are supposed to occasion this disorder being like other insects, killed by the sulphureous steams which exhale by the heat of the body. As to the internal use of mercury, which some have accounted a specific, there are several instances of men undergoing a complete salivation for the cure of the lues venerea, without being freed from the itch; but there are also a multitude of instances of men undergoing a long course of sulphur without effect, and who were afterward readily cured by mercury.

The quantity of ointment, above directed, serves for four unctions: the patient is to be rubbed every night; but to prevent any disorder that might arise from stopping too many pores at once, a fourth part of the body is to be rubbed at one time. Though the itch may thus be cured by one pot of ointment, it will be proper to renew the application, and to touch the parts most affected for a few nights longer, till a second quantity also be exhausted: and in the worst cases, to subjoin the internal use of sulphur, not with a view to purify the blood, but to dissipate the steams more certainly through the skin: there being reason to believe, that the animalcula may sometimes lie too deep to be thoroughly destroyed by external applications.

Tutty ointment.

654 Take of prepared tutty one dram; ointment of spermaceti, what is sufficient. Mix them so as to make a soft ointment. L.

Take of simple liniment, five parts; prepared tutty, one part. E.

These ointments have long been celebrated, and are still much employed against affections of the eyes. But they cannot, we imagine, be esteemed elegant.

Both calamine and tutty act only by means of the zinc they contain, and calamine appears to contain the most of the two, and likewise to be the least variable in its contents. But the pure flowers prepared from zinc itself are doubtless preferable to either. Hence the ointment of tutty may be considered as inferior to both the ointment of calamine and to the ointment of the calx of zinc, which have also a place in our pharmacopœia.

Simple liniment. L.

655 Take of olive oil, four parts; white wax, one part.

This consists of the same articles which form the simple ointment of the Edinburgh pharmacopœia, but merely in a different proportion, so as to give a thinner consistence; and where a thin consistence is requisite, this may be considered as a very elegant and useful application.

Liniment of ammonia.

656 Take of water of ammonia, half an ounce; olive-oil,

one ounce and a half. Shake them together in a phial till they are mixed.

This has long been known in the shops under the title of *volatile liniment*, but is now more properly denominated from the principal active article, which enters its composition. It has been much employed in practice, particularly on the recommendation of Sir John Pringle in his Observations on the Diseases of the Army. He observes, that, in the inflammatory quinsey, or strangulation of the fauces, a piece of flannel, moistened with this mixture, applied to the throat, and renewed every four or five hours, is one of the most efficacious remedies. By means of this warm stimulating application, the neck, and sometimes the whole body is put into a sweat, which after bleeding either carries off or lessens the inflammation. Where the skin cannot bear the acrimony of this mixture, a larger proportion of oil may be used.

Stronger liniment of ammonia.

Take of water of pure ammonia, one ounce; olive oil, two ounces. Shake them together in a phial. 657

This article differs from the foregoing in strength only. This arises both from its being formed of a more acrid spirit, and from its containing that spirit in a larger proportion to the oil. It is used to supply the place of the *epithemia et emplastrum volatile* of our former pharmacopœias, and is a very acrid stimulating composition. When largely applied, it often excites inflammation, and even vesication, on tender skin. It is often however successfully employed against obstinate rheumatic and ischiadic pains.

Camphor liniment. L.

Take of camphor, two ounces; water of ammonia, six ounces; simple spirit of lavender, sixteen ounces. Mix the water of ammonia with the spirit, and distil from a glass retort, with a slow fire, sixteen ounces. Then dissolve the camphor in the distilled liquor. 658

This formula, which has now for the first time a place in the London pharmacopœia, approaches to the volatile essence of that celebrated empiric the late Dr Ward: But the above is a more elegant and active formula than either of the receipts published by Mr Page, from Dr Ward's book of receipts; and there is no reason to doubt that it will be equally effectual in removing some local pains, such as particular kinds of headach, in consequence of external application.

Soap liniment. L.

Take of soap, three ounces; camphor, one ounce; spirit of rosemary, one pint. Digest the soap in the spirit of rosemary until it be dissolved, and add to it the camphor. 659

This is the soap liniment of the former edition of the London pharmacopœia, without any alteration: and it differs very little from the soap-balsam of the Edinburgh college already mentioned. Though a less active and penetrating application than the preceding, it is perhaps no less useful: and it is often successfully employed for external purposes against rheumatic pains, sprains bruises, and similar complaints.

Prepara-
tions and
Composi-
tions.

660

Egyptian ointment. Gen.

Take of honey, one pound: strong vinegar half a pound; verdegris, powdered, five ounces. Let the ingredients be boiled together till the verdegris be dissolved, so that the ointment may have a due degree of thickness and a purple colour.

This preparation had formerly a place in our pharmacopœias under the title of *Egyptian honey*: and a similar preparation has now a place under the title of *oxymel of verdegris*. But in that formula, the proportion is much less than in the above. It may justly be considered as a very powerful application for cleansing and detaching foul ulcers, as well as for keeping down fungous flesh. But these purposes may in general be answered by articles less acrid, and exciting less pain. Besides this, the above preparation is also liable to considerable uncertainty with respect to strength; for a large proportion of the verdegris will in a short time subside to the bottom; thus, what is in the top of the pot is much less active than that in the bottom.

Anodyne ointment. Gen.

661 Take of olive-oil, ten drams; yellow wax, half an ounce; crude opium, one dram. Mix them according to art, so as to form an ointment.

Opium thus externally applied, will in some degree be productive of the same effect as when used under the form of the anodyne balsam. In that state it produces its effects more immediately; but under the present form its effects are more permanent. Besides this, the present ointment furnishes us with an useful dressing for sores attended with severe pain: to which opium when dissolved in spirit cannot be applied. Hence the present, or some analogous formula, is well intitled to a place in our pharmacopœias.

Ointment for an ulcerated cancer. Brun.

662 Take of the recently expressed juice of the ricinus, one pound: let it be exposed to the rays of the sun in a leaden vessel till it acquire the consistence of an oil; then to one pound of this inspissated juice add calcined lead, white precipitate mercury, each one pound. Let them be properly mixed.

This acrid application must possess a considerable degree of corrosive power. And in some cases of cancer, by the proper application of corrosives much benefit may be done: But where the disease has made any considerable progress, these will in general have the effect rather of halting its progress than of removing it; particularly if there be a large indolent tumor below the ulcer.

Digestive ointment. Ross.

663 Take of Venice turpentine, one pound; the yolks of eight eggs. Mix them together according to art.

This warm stimulating application is well fitted to promote the suppurative inflammation, and may be advantageously had recourse to, where it is necessary to encourage a large discharge of pus.

Hæmorrhoidal ointment.

664 Take of saturnine ointment, six drams; oil of hyocy-

mus, obtained by boiling, two drams; camphor, powdered, two scruples; saffron one, scruple. Mix them into an ointment.

The name affixed to this ointment expresses the purpose for which it is applied. From the articles of which it consists, it may be concluded, that it possesses a gently emollient and anodyne power; and may therefore afford considerable relief, where much pain arises from external hæmorrhoidal tumors.

Prepara-
tions and
Composi-
tions.*Laurel ointment.* Succ.

Take of prepared mutton-suet, eight ounces. After it is melted and removed from the fire, add to it oil of bays, one pound; ethereal oil of turpentine, one ounce: rectified oil of amber, half an ounce. Let them be mixed and rubbed together till they form an ointment.

This is an improved mode of forming an ointment which had formerly a place in our pharmacopœias under the title of *nervine ointment*. And it furnishes a warm stimulating nervine application, which may in some degree restore sense and motion to paralytic limbs. And while it at least serves to lead to the careful use of friction, it may somewhat increase the benefit which would result from it.

Ointment of tobacco. Dan.

Take of the leaves of tobacco, three pounds; juice of tobacco, nine ounces; hog's lard, a pound and a half; resin, three ounces. Let the cut leaves be macerated for the space of a night, and then boiled over a gentle fire. Having strained the fluid obtained by expression, add to it yellow wax, half an ounce; powder of the root of birthwort, three ounces. Mix them into an ointment.

There can be no doubt that tobacco externally applied has very powerful effects on the human body; and that not merely from its topical action, but sometimes even as affecting the system in general. From this last circumstance it requires to be used with great caution. It has, however, been found, under proper management, to afford an effectual cure in obstinate cutaneous affections. But were it to be used with this intention, we would have a more elegant formula, by merely impregnating either hog's lard, or the simple ointment, with the active qualities extracted by the aid of heat from the leaves of the prepared tobacco in the state in which it is usually brought to us from America, than by having recourse to the recent juice, and to the aristolochia and other additions here directed.

Ointment of storax. Succ.

Take of olive oil, a pound and a half; white resin, gum elemi, yellow wax, each seven ounces. After they are melted together and strained, add liquid storax, seven ounces. Mix them together, and agitate the mixture till it concretes into an uniform ointment.

An ointment supposed to derive its activity from the storax, though it have no place in our pharmacopœias, is received into most of the foreign ones. And it has been much celebrated not only as a strengthening application to weakly children, but even for the removal of affections of the bones, as in cases of rach-

Prepara-
tions and
Composi-
tions.

tis and the like. It is, however, very doubtful how far these properties depend on the storax. If it have really any good effect, it is probable that this is more the consequence of the friction merely, than of any of the articles which enter the composition of the ointment. But there is reason to believe that the virtues attributed to this ointment are more imaginary than real.

Onion ointment. Succ.

- 668 Take of yellow wax, resin, each half a pound. To these melted, add onions roasted under the ashes, honey, each two pounds and a half; black soap, half a pound. Let them be gently boiled together till all the moisture be consumed, then strain the liquor, expressing it from the materials, and afterwards agitate it with a wooden pestle that it may unite into one uniform mass.

This ointment is applied with the intention of promoting suppuration. And it has long been supposed, that the onion, especially in its roasted state, has a remarkable influence in this way: but there is reason to think, that the powers attributed to it have been greatly over rated. And there is even ground to presume that these effects totally depend entirely on heat and moisture. Hence no application is perhaps better suited for promoting suppuration than a poultice of bread and milk, applied as hot as can be borne with, and frequently repeated.

CHAP. XXXIII. *Cerates.*

- 669 CERATES are substances intended for external application, formed of nearly the same materials which constitute ointments and plasters. And they differ principally from these in being merely of an intermediate consistence between the two. Accordingly, they are seldom the subject of a separate chapter by themselves, but are classed either with the one or the other. In the Edinburgh pharmacopœia they are classed among the ointments; but as the London college have referred them to a separate head, we shall here also consider them by themselves.

Simple cerate. E.

- 670 Take of olive oil, six parts; white wax, three parts; spermaceti, one part. Unite them according to art. This differs from the simple ointment in containing a greater proportion of wax to the oil, and in the addition of the spermaceti. But by these means it obtains only a more firm consistence, without any essential change of properties.

Cerate of cantharides, or Spanish flies. L.

- 671 Take of cerate of spermaceti, softened with heat, six drams; Spanish flies, finely powdered, one dram. Mix them.
Under this form cantharides may be made to act to any extent that is requisite. It may supply the place either of the blistering plaster or ointment; and there are cases in which it is preferable to either. It is particularly more convenient than the plaster of cantharides, where the skin to which the blister is to be applied is previously much affected, as in cases of small-

pox; and in supporting a drain under the form of issue, it is less apt to spread than the softer ointment.

Prepara-
tions and
Composi-
tions.

Calamine cerate. L.

- Take of calamine prepared, yellow wax, each half a pound; olive oil, one pint. Melt the wax with the oil; and, as soon as the mixture begins to thicken, mix with it the calamine, and stir the cerate until it be cold.

672

Cerate of Calamine. E.

- Take of simple cerate, five parts; calamine prepared, one part.

These compositions are formed on the cerate which Turner strongly recommends in cutaneous ulcerations and excoriations, and which has been usually distinguished by his name. They appear from experience to be excellent epulotics, and as such are frequently used in practice.

Cerate of acetated litharge. L.

- Take of water of acetated litharge, two ounces and a half; yellow wax, four ounces; olive oil, nine ounces; camphor, half a dram. Rub the camphor with a little of the oil. Melt the wax with the remaining oil; and as soon as the mixture begins to thicken, pour in by degrees the water of acetated litharge, and stir constantly until it be cold; then mix in the camphor before rubbed with oil.

673

This application has been rendered famous by the recommendations of Mr Goulard. It is unquestionably in many cases very useful. It cannot, however, be considered as varying essentially from the fatumille ointment, or ointment of acetated ceruse, formerly mentioned. It is employed with nearly the same intentions, and differs from it chiefly in consistence.

Cerate of yellow resin. L.

- Take of ointment of yellow resin, half a pound; yellow wax, one ounce. Melt them together, and make a cerate.

674

This had formerly the name of *lemon-ointment*. It is no otherwise different from the yellow basilicum, or ointment of yellow resin, than being of a stiffer consistence, which renders it for some purposes more commodious.

Soap cerate. L.

- Take of soap eight ounces; yellow wax, ten ounces; litharge, powdered, one pound; olive oil, one pint; vinegar, one gallon; boil the vinegar with the litharge over a slow fire, constantly stirring until the mixture unites and thickens; then mix in the other articles, and make a cerate.

675

This, notwithstanding the name, may rather be considered as another fatumine application; its activity depending very little on the soap; and it may be held as varying in little else but consistence from the plaster of litharge. It can hardly be thought to differ in its properties from the cerate of acetated litharge just mentioned; for neither the small proportion of camphor which enters the composition of the one, nor the soap which gives name to the other, can be considered as having much influence.

Cerate

Cerate of spermaceti. L.

Take of spermaceti, half an ounce; white wax, two ounces; olive oil, four ounces. Melt them together, and stir until the cerate be cold.

This had formerly the name of *white cerate*, and it differs in nothing from the ointment of spermaceti, or white liniment, as it was formerly called, excepting in consistence, both the wax and the spermaceti bearing a greater proportion to the oil.

Lip salve. Ross.

677 Take of olive oil, eighteen ounces; white wax, one pound; spermaceti, an ounce and a half; oil of rhodium, half a dram. Form a cerate, tinging it with alkanet, so as to give a red colour.

The name affixed to this cerate points out the use for which it is intended. It is chiefly employed against those chaps and excoriations of the lips, which are often the consequence of cold weather; and it is very well suited for removing affections of that kind. But excepting in the colour and smell which it derives from the alkanet and rhodium, it differs in nothing from the cerate of spermaceti, and cannot be considered as more effectually answering the intention in view.

Bougies. Suec.

678 Take of yellow wax, melted one pound; spermaceti, three drams; vinegar of litharge, two drams. Mix them, and upon removal from the fire immerse into the mixture slips of linen, of which bougies are to be formed according to the rules of art. These may also be made with double, triple, or quadruple, the quantity of the vinegar.

It is perhaps rather surprising, that no formula for the preparation of bougies has a place in our pharmacopœias: for there can be no doubt, that although the preparation of them has hitherto been principally trusted to empirics; yet in the hand of the skilful practitioner they are of great service in combating obstinate affections. Although it has been pretended by some that their influence is to be ascribed to certain impregnations; yet it is on better grounds contended, that they act entirely on mechanical principles. The great object is therefore to obtain the union of a proper degree of firmness and flexibility. These qualities the above composition possesses; and it does not probably derive any material benefit from being prepared with an additional proportion of the vinegar of litharge.

CHAP. XXXIV. *Epithems.*

679 By epithems or cataplasms are in general understood those external applications which are brought to a due consistence or form for being properly applied, not by means of oily or fatty matters, but by water or watery fluids. Of these not a few are had recourse to in actual practice; but they are seldom prepared in the shops of the apothecaries; and in some of the best modern pharmacopœias no formulæ of this kind are introduced. The London college, however, although they have abridged the number of epithems, still retain a few. And it is not without some advantage that there are fixed forms for the preparation of them.

Vol. XIV.

Cataplasm of cummin. L.

Take of cummin-seed, one pound; bay-berries, dry leaves of water-germander, or scordium, Virginian snake-root, of each three ounces; cloves, one ounce.

Rub them all together; and, with the addition of three times the weight of honey, make a cataplasm.

This is adopted into the present edition of the London pharmacopœia with a very little alteration from the last. It was then intended as a reformation of the *iberiaca Londinensis*, which for some time past has been scarcely otherwise used than as a warm cataplasm. In place of the numerous articles which formerly entered that composition, only such of its ingredients are retained as contribute most to this intention: but even the article from which it now derives its name, as well as several others which still enter it, probably contribute very little to any medical properties it may possess.

Mustard-cataplasm. L.

Take of mustard seed, powdered, crumb of bread, each half a pound; vinegar, as much as is sufficient. Mix, and make a cataplasm.

Epithems of this kind are commonly known by the name of *sinapisms*. They were formerly not unfrequently prepared in a more complicated state, containing garlic, black-soap, and other similar articles; but the above simple form will answer every purpose which they are capable of accomplishing. They are employed only as stimulants: they often inflame the part and raise blisters, but not so perfectly as cantharides. They are frequently applied to the soles of the feet in the low state of acute diseases, for raising the pulse and relieving the head. The chief advantage they have depends on the suddenness of their action.

Alum-curd. L.

Take the whites of two eggs; shake them with a piece of alum till they be coagulated.

This preparation is taken from Riverius. It is an useful astringent epithem for sore, moist eyes, and excellently cools and represses thin desfluxions. Slighter inflammations of the eyes, occasioned by dust, exposure to the sun, or other similar causes, are generally removed by fomenting them with warm milk and water, and washing them with solutions of white vitriol. Where the complaint is more violent, this preparation, after the inflammation has yielded a little to bleeding, is one of the best external remedies. It is to be spread on lint, and applied at bed-time.

A TABLE, showing in what Proportions MERCURY or OPIUM enter different Formulæ.

Pulvis creta compositus cum opio. L. In about forty-four grains, one grain of opium is contained.

Pulvis ipecacuanha compositus. L. In ten grains, one grain of opium.

Pulvis sudorificus. E. In eleven grains, one grain of opium.

Pulvis opiatu. L. In ten grains, one grain of opium.

Pulvis scammonio cum calomelanc. L. In four grains, one grain of calomel.

Prepara-
tions and
Composi-
tions.

Pilula ex opio. L. In five grains, one grain of opium.
Pilule thebaicæ. E. In ten grains, one grain of opium.
Pilule ex hydrargyro. L. In two grains and a half, one grain of mercury.
Pilule ex hydrargyro. E. In four grains, one grain of mercury.
Pilule plummeri. E. In two grains and two-thirds, one grain of calomel.
Confectio opiatæ. L. In thirty-six grains, one grain of opium.
Electuarium Japonicum. E. In about one hundred and ninety-three grains, one grain of opium.
Electuarium Thebaicum. E. In ninety-seven grains, one grain of opium.
Trochisci bebi i cum opio. E. In fifty-five grains, one grain of opium.
These trochisci are not unfrequently ordered *cum duplicæ opio*, and under this form are kept in many shops.
Emplastrum ammoniacum cum hydrargyro. L. In five ounces, one ounce of mercury.
Emplastrum hydrargyri cum hydrargyro. L. In five ounces, one ounce of mercury.
Emplastrum e hydrargyro. E. In three ounces and two-thirds, one ounce of mercury.
Unguentum hydrargyri fortius. L. In two drams, one dram of mercury.

Unguentum hydrargyri mitius. L. In five drams, one dram of mercury.
Unguentum ex hydrargyro. E. In five drams, one dram of mercury.
Unguentum hydrargyri nitrati. L. In one dram, four grains of nitrated quicksilver.
Unguentum citrinum. E. In one dram, four grains of nitrated quicksilver.
Unguentum calcis hydrargyri albæ. L. In one dram, four grains and two-thirds of the calx hydrargyri albæ.
Tinctura opii (L.) is made with opium, in the proportion of one grain to about thirteen of the menstruum.
Tinctura Thebaica (E.) is made with opium, in the proportion of one grain to twelve of the menstruum.
Tinctura opii camphorata (L.) is made with opium, in the proportion of one grain to two hundred and sixty of the menstruum.
Elixir pægoricum (E.) is made with opium, in the proportion of one grain to sixty-eight of the menstruum.
Balsamum anodynum (E.) is made with opium, in the proportion of one grain to about thirty of the menstruum.

Calaminz, prepared, 92. Cerate of, 672.
Calcination, 89.
Calcined zinc, 314.
Calomel, 292.
Camomile, essential oil of, 184. Flower-water, 338.
Camphor, 34. Water, 334. Liniment, 658.
Camphorated tincture of opium, 456. Spirit of wine, 469. Mixture, 479. Spirit, 488.
Cancer, ointment for an ulcerated, 662.
Cantbarides, cerate of, 671.
Carbonic acid, 12.
Cardamom tincture, 430. Compound ditto, 431.
Carme'ite water, 366.
Caraway spirit, or spirituous water, 355. Essential oil of, 158, 159. Seeds, 162.
Cascarilla, extract of, 141. Tincture of, 432.
Cassia water, 324. Electuary of, 591.
Castor oil, 153. Water, 335. Tincture, 433. Compound ditto, 434.
Cataplasm of cummin, 680. Of mustard, 681.
Catichu, decoction of, 406. Tincture of, 435. Troches of, 568.
Cathartic salt of Glauber, 232.
Caulic ley, 214. Strongest common, 216. Milder ditto, 218. Lunar, 272.
Cephalic or sternutatory powder, 534.
Cerates, 669—679.
Ceruse of antimony, 268; or white lead, 307. Acetated, 308. Powder of, 535. Ointment of acetated, n° 643. Ointment of, 644.
Chalk, prepared, 93. Julep, 374. Mixture or drink, 480. Compound powder of, &c. and combined with opium, 538. Troches of, 566.
Chervil, conserve of, 111. Water, 336.
Chocolate nuts, oil of, 155.
Cinnamon, essential oil of, 185. Water, 323. Spirit of, or spirituous water, 356. Tincture of, 436. Compound ditto, 437. Syrup of, 517.
Cloves of julyflower, syrup of, 498. Essential oil of, 183.
Clyster, decoction for, 376.
Coccie pills, 573.
Colcothar of vitriol, 280.
Colecium, 403. Syrup of, 499.
Colonyth tincture, 473. Pills with aloes, 573.
Colomba, tincture of, 438.
Coloquintida compound extract of, 135.
Commination, 87.
Common decoction, 378. Plaster, 620.
Confection, japonic, 594. Of various kinds, 601—606.
*Conserve*s, 108—121.
Contrayerva, compound powder of, 537.
Copper, preparations of, and zinc, 314—319. Volatile tincture of, 474. Pills, 574. Water of ammoniated, 609.
Cordial electuary or confection, 603.
Corn plaster, 629.
Corrosive sublimate of mercury, 290. Solution of, 291. Red oil, 296. Pills of, 586. Plaster of, 631.
Coxentry remedy, 559.
Crabs claws, compound powder of, 536.
Crocus of antimony, 257. Opening and atrugent of iron, 282.
Crystallization, 80.
Cummin, catalaplam of, 680. Plaster, 617.
Curd, alum, 682.
Currents, black inspissated juice of, 127. Syrup of black, 502.
 D.
Dandelion, extract of, 147.
Deadly nightshade plaster, 628.
Decoctions and infusions, 371—407.
Defensive plaster, 627.
Democrates, confection of, 650. *Dipuration*, n° 79.
Diacassia, electuary of, 591.
Dia odium, 503.
Digestion, long, extracts by, 132.
Digestive powder, 552. Ointment, 663.
Dill or dill seed water, 322.

- Nitre*, purified, 233. Vinous acid, or dulcified spirit of, 357. Troches of, 564.
- Nitrous* acid, 197. Weak, 198. Ether, spirit of, 351. Powder, 556. Electuary, 598.
- Nutmeg*, essential oil of, 190. Spirit of, or spirituous nutmeg-water, 361.
- Nux vomica*, tincture of, 477.
- O.
- Odorous* principle of vegetables, 35.
- Oil* of almonds, 152. Of hartshorn, 227.
- Oils*, gross, 29. Essential, 31, 32, 33. Of vegetables, rectified spirit of wine a menstruum for, 73. Of the mineral kingdom, 49. Dissolve various substances, 74. Dissolved by alkaline lixivium, 76. Expressed, &c. 151—158. Essential, &c. 158—196. Salt and oil of amber, 178. 206.
- Ointments* and liniments, 635—669.
- Olive*s, expressed oil of, 154.
- Onion* ointment, 668.
- Opiate* powder, 542.
- Opium*, purified, 144. Extract of, prepared by long digestion, 145. Tincture of, 455. Camphorated tincture of, 456. Pills, 579. Confection of, 604.
- Orange-peel*, conserve of the yellow rind of that of Seville, 112. Water, 332, 368. Tincture of, 439. Syrup of, 500.
- Orange-skins*, essential oil of, 182.
- Origanum*, essential oil of, 159. Ditto of leaves of, 166.
- Oxymel* of verdegrise, 523. Of meadow saffron, 524. Of squills, 525. Simple, 526. Of garlic, 527. Pectoral, 528.
- P.
- Pabulum* of vegetables, 4.
- Pacific* pills, 579.
- Palm*, expressed oil of, 154.
- Panaea* of antimony, 270.
- Paregoric* eixir, 456.
- Pectoral* oxymel, 528. White troches, 561. Black ditto 562. Troches with opium, 563.
- Pennyroyal*, essential oil of, 159. Ditto

- Ditto of leaves of, 167. Water, 329. Spirit of, 363.
Peppermint, essential oil of, 159, 160. Ditto of leaves, 164. Water, 326. Spirit of, or spirituous water, 359.
Peru, tincture of the balsam of, 426.
Peruvian bark, extract of, 138, 140. Ditto with resin, 139. Decoction of, 375. Infusion of, 404. Tincture of, 440. Compound ditto, 441. Purgive powder, 557.
Pharmacy defined, 1. Objects of, 2.
Pills, lunar, 273. Of various kinds, and general rules for making, 569—590.
Pimento, or all-spice, spirit of, 362; or spirituous Jamaica pepper water, *ibid.*
Piich, plaster of Burgundy, 624. Plaster, 634.
Plants, differ in the different periods of their growth, 6. Different parts of the same plant of different qualities, 7.
Plasters, 613—635.
Poppy, syrup of white, 503. Ditto of red, 504.
Potash, 23.
Powder, antimonial, 260. Ash-coloured of mercury, 287.
Powders, manner of making, and various kinds of, 529—560.
Powdere l tin, 312.
Precipitation, 81.
Preparation of substances not soluble in water, 90, &c. Of hog's lard and mutton-suet, 94. Of millipeds, 99.
Prepared antimony, 91. Calamine, 92. Chalk, 93. Rust or shavings of iron, 105. Kali, 210. Natron, 219. Ammonia, 221.
Press, use of, in expressing juices, 85.
Pulps extraction, 100.
Purgive Peruvian powder, 557.
Purification of gum ammoniac, 95. Of honey, 98. Of borax, 103. Of alum, 242.
Purified filings of iron, 104. Scales of iron, 106. Opium, 144. Fixed fossile alkaline salt, 220. Nitre, 233. Sal ammoniac, 247.
Putrefactive fermentation, 18, 19.
- Q.**
Quassia, tincture of, 475.
Quicksilver, purified, 284. Acetated, 285. Calcined, 286. With chalk, 288. Muriated, 289. Mild muriated, 294. Red nitrated, 295. White calc of, 297. With sulphur, 299. Red sulphurated, 301. Vitriolated, 302. Syrup of, 519. Pills, 576. Ointment of the white calc of, 638. Stronger ditto, 647. Weaker ditto, *ibid.*; or blue ointment, *ibid.* Ointment of nitrated, 648.
Quince-seed, mucilage of, 391.
- R.**
Raspberry juice, syrup of, 502.
Rectified spirit of wine, a menstruum for essential oils and resins of vegetables, 73. On extracts with, 130. Oil of turpentine, 175. Oil of horns, 177. Oil of amber, 179.
Red nitrated quicksilver, 295. Corrosive or precipitated mercury, 296. Lead, 306. Poppy syrup, 504.
Refined liquorice, 150.
Resins, 36. Extracts, &c. 128—151. Resinous substances dissolved by alkaline lixivium, 76. Extract of Peruvian bark with, 139. Ointment of yellow, 650. Cerate of ditto, 674.
Rhodium, essential oil of, 187.
Rhubarb, infusion of, 397. Wine of, 415. Various tinctures of, 457. Elixir of, 458.
Rochel salt, 237.
Rob, or inspissated juice of elder berries, 124.
Roses, infusion of, 396. Conserve of the buds of red, 111. Vitriolated conserve of, 120. Tincture of, 396. Vinegar of, 401. Syrup of pale, 505. Of dry, 506. Honey of, 521. Water, 330.
Rosmary, essential oil of, 159. Ditto of tops of, 160, 168. Spirit of 365.
Rue, essential oil of, 191. Water, 343.
Rufus pills, 572.
Rust of iron, prepared, 105, 276.
- S.**
Saffron, tincture of, 442. Syrup of, 501. Oxymel of meadow, 524.
Sage water, 346.
Sal ammoniac, volatile, 223. Spirit of, 224. Ditto with quicklime, 226.
Saline mixture or julep, 493.
Salt and oil of amber, 178, 206. Purified ditto of amber, 207. Of tartar, 209. Fixed vegetable alkaline, 211. Fixed fossile alkalized, purified, 220. Of harts-horn, 227. Of many virtues, 230. Cathartic of Glauber, 232. Rochel, 241. Or fugar of milk, 244. Of sorrel, 245. Acid of borax, 246. Ammoniac, purified, 247. Of silver, 272. Of steel, 279, &c.
Salts, and fine preparations of vegetables, p. 273, n^o 39, 40, 41. Alkaline, dissolved by acids, 75. Chapter on, &c. 196—248.
Salve for lips, 677.
Sap of vegetable, 28.
Sapphire-coloured water, 609.
Saponaceous balsam or liniment, 471. Plaster, 625.
Sarsaparilla, decoction of, 384. Compound ditto, 385.
Sassafras root, essential oil of, 159, and 170.
Saturine ointment, 643.
Savin, essential oil of, 160. Ditto of leaves of, 171. Water, 344. Compound tincture of, 459.
Savory, essential oil of, 192.
Scales of iron purified, 106.
Scammony, compound powder of, 543. Ditto with aloes, 544. Ditto with colomel, 545. Electuary of, 592.
Scurvy-grass, spirit of, 367.
Sabaceous matter, 30.
Seneka, decoction of, 386.
Senna, extract of, 143. Simple infusion of, 393. Tartarized ditto, 394. Infusion of tamarinds with, 395. Tincture of, 462. Compound powder of, 546. Electuary of, 593.
Seville orange-peel, conserve of the yellow rind of, 112.
Shavings of rust of iron, prepared, 105.
Silver, preparations of, 271—274.
Simple ointment, 636. Liniment, 655. Cerate, 670.
Slies, conserve of, 116.
Snake root, tincture of, 463.
Soap pills, 588. Plaster, 625. Liniment, 659. Cerate, 675.
Soda, 25. Vitriolated, 232. Tartarized, 241.
Solids, sublimation of, 84.
Solution, in the humid and dry way, 71. Principal menstrua for, 72. Simple mercurial, 304. Mineral of ar-
- fenic, 494.
Soot, tincture of, 444.
Sorrel, salt of, 245.
Spanish flies, tincture of, 429. Plaster of, 615. Ointment of, 640. Cerate of, 671.
Spearmint, conserve of the leaves of, 113. Essential oil of, 159. Water, 327. Spirit of, 360.
Spermaceti, ointment of, 652. Cerate of, 676.
Spices, aromatic, 533.
Spirit of wine rectified, a menstruum for essential oils or resins of vegetables, 73. On extracts with, 130. On extracts with and water, 131. Spirit of sal ammoniac, 224. Ditto with quicklime, 226. Of Mindererus, 237. Camphorated of wine, 469. Compound of vitriolic ether, 485. Ditto of ammonia, 486. Succinated ditto of ammonia, 487. Volatile aromatic, &c. 486. Camphorated, 488.
Spirits, distilled, 347—371.
Sponge, burning of, 102. Powder, 559.
Squills, drying of, 101. Conserve of, 117. Vinegar of, 399. Wine of, 417. Tincture of, 460. Syrup of, 507. Honey of, 522. Oxymel of, 525. Pills, 580.

Zedoary wine, 418.
Zinc, preparations of, and copper, 314—319. Water of, vitriolated, with camphor, 611. Ointment of the calx of, 639.

P H A

P H A

Pharos. PHAROS, (Homer, Strabo, &c.) a small oblong island, adjoining to the continent of Egypt, over-against Alexandria. On this island stood a cognominal light tower, of four sides, each side a stadium in length: and the tower so high as to be seen 100 miles off. Some affirm, each of its four corners rested on a large sea-crab of glass or of hard transparent stone of Ethiopia or Memphis. Others imagine the crabs were only added externally to the base by way of ornament, or as emblematical of its situation and use. The architect was Sostratus the Cnidian, as appears by an inscription on the tower, under Ptolemy Philadelphus, who laid out 800 talents upon it. On account of the port of Alexandria, the entrance to which was difficult and dangerous, the Pharos was called the *key of the Egyptian sea*, or even of Egypt itself (Lucan): and Pharos, from being a proper name, is become an appellative to denote all light houses.

PHAROS, or *Phare*, a light-house; a pile raised near a port, where fire is kept burning in the night, to guide and direct vessels near at hand. The pharos of Alexandria, built in the island of Pharos, at the mouth of the Nile, was anciently very famous, inasmuch as to communicate its name to all the rest. This most magnificent tower consisted of several stories and galleries, with a lantern at top, in which a light being continually burning, might be seen for many leagues at sea, and along the coast. It was accounted one of the seven wonders of the world. It was built by the famed architect Sostratus, a native of Cnidos, or, according to some, by Deiphanes, the father of Sostratus; and cost Ptolemy Philadelphus 800 talents. The several stories were adorned with columns, ballustrades, galleries of the finest marble and workmanship; to which some add, that the architect had contrived to fasten some looking-glasses, so artificially against the highest galleries,

Pharos.

Pharpar,
Pharfalia.

galleries, that one could see in them all the ships that sailed on the sea for a great way. Instead of which noble structure, one sees now only a kind of irregular castle, without ditches or outworks of any strength, the whole being accommodated to the inequality of the ground on which it stands, and which it seems is no higher than that which it should command. Out of the midst of this clumsy building rises a tower, which serves for a light-house, but which hath nothing of the beauty and grandeur of the old one. The Colossus of Rhodes also served as a pharos.

PHARPAR, or PHARPHAR, is one of the rivers of Damascus, or rather it is an arm of the Barrady or Chrysothoas, which waters the city of Damascus and the country about it (2 Kings v. 12.) "Are not Abana and Pharpar, rivers of Damascus, better than all the waters of Israel?" The river of Damascus has its fountain in the mountains of Libanus. At its approach to the city it is divided into three arms, one of which passes through Damascus. The other two water the gardens round about, and then reuniting, they lose themselves at four or five leagues from the city, towards the north. See *Maunderell's Travels from Aleppo to Jerusalem*; see also the articles ABANA and DAMASCUS.

PHARSALIA, PHARSALIUM, *Pharfalus*, or *Pharfalos*, (anc. geog.), a town of the Phthiotis, a district of Thessaly, near Phæra and Larissa, to which last place Pompey fled from the plains of Pharfalus; watered by the river Enipeus, which falls into the Apidanus, and both together into the Peneus. Between Pharfalus and Enipeus, Pompey drew up his men at the fatal battle of Pharfalia.

In this battle, the advantage with respect to numbers was greatly on the side of Pompey. That general himself was on the left with the two legions which Cæsar had returned to him at the beginning of the war. Scipio, Pompey's father-in-law, was in the centre, with the legions he had brought from Syria, and the reinforcements sent by several kings and states of Asia. The Cilician legion, and some cohorts which had served in Spain, were in the right, under the command of Afranius. As Pompey's right wing was covered by the Enipeus, he strengthened the left with his slingers, archers, and the 7000 Roman horse, on whom chiefly his party founded their hopes of victory. The whole army was drawn up in three lines, with very little spaces between them. In conformity to this disposition, Cæsar's army was drawn up in the following order: The tenth legion, which had on all occasions signalized themselves above all the rest, was placed in the right wing, and the ninth in the left; but as the latter had been considerably weakened in the action at Dyrrhachium, the eighth legion was posted so near it as to be able to support and reinforce it upon occasion. The rest of Cæsar's forces filled up the space between the two wings. Marc Antony commanded the left wing, Sylla the right, and Caius Domitius Calvinus the main body. As for Cæsar, he posted himself in the right over-against Pompey, that he might have him always in his sight.

Thus was the whole plain covered, from Pharfalia to the Enipeus, with two armies, dressed and armed after the same manner, and bearing the same ensigns, the Roman eagles. Pompey observing how well the

enemy kept their ranks, expecting quietly the signal of battle, and on the contrary how impatient and unsteady his own men were, running up and down in great disorder for want of experience, he began to be afraid lest his ranks should be broken upon the first onset; and therefore commanded the foot in the front to keep their ground, and quietly wait for the enemy. The two armies, though within reach of each other, kept a mournful silence; but at length the trumpets sounded the charge, and Cæsar's army advanced in good order to begin the attack, being encouraged by the example of one Caius Crastinus, a centurion, who at the head of 120 men threw himself upon the enemy's first line with incredible fury. This he did to acquit himself of a promise he had solemnly made to Cæsar, who, meeting him as he was going out of his tent in the morning, asked him, after some discourse, *What his opinion was touching the event of the battle?* To which he, stretching out his hand, replied aloud, *Thine is the victory, Cæsar; thou shalt gloriously conquer, and I myself this day will be the subject of thy praise either dead or alive.* In pursuance of this promise he broke out of his rank as soon as the trumpet sounded; and, at the head of his company, ran in upon the enemy, and made a great slaughter of them. But while he was still pressing forward, forcing his way through the first line, one of Pompey's men ran him in at the mouth with such violence, that the point of his sword came out at the hind part of his neck. Upon his death Pompey's soldiers took courage, and with great bravery flood the enemy's onset. While the foot were thus sharply engaged in the centre, Pompey's horse in the left wing marched up confidently; and having first widened their ranks, with a design to surround Cæsar's right wing, charged his cavalry, and forced them to give round. Hereupon Cæsar ordered his horse to retreat a little, and give way to the six cohorts, which he had posted in the rear as a body of reserve. These, upon a signal given, coming up, charged the enemy's horse with that resolution and good order which is peculiar to men who have spent all their lives in camps. They remembered their instructions, not striking at the legs or thighs of the enemy, but aiming only at their faces. This unexpected and new manner of fighting had the desired effect. For the young patricians, whom Cæsar contemptuously calls the *pretty young dancers*, not being able to bear the thoughts of having their faces deformed with scars, turned their backs, and, covering their faces with their hands, fled in the utmost confusion, leaving the foot at the mercy of the enemy. Cæsar's men did not pursue the fugitives; but charging the foot of that wing, now naked and unguarded, surrounded them, and cut most of them in pieces.

Pompey was so transported with rage, in seeing the flower of his forces thus put to flight or cut in pieces, that he left his army, and retired slowly towards his camp, looking more like a man distracted and beside himself than one who by his exploits had acquired the name of *the Great*. When he had reached the camp, he retired to his tent without speaking a word to any; and continued there, like one distracted and out of his senses, till his whole army was defeated. Cæsar no sooner saw himself master of the field than

Pharfalia.

Pharfalia. he marched to attack the enemy's entrenchments, that Pompey might not have time to recollect himself. When Pompey was informed that his rival was advancing to attack his entrenchments, he then first seemed to have recovered his senses, and cried out, *What, into my camp too!* He said no more; but immediately tying aside the marks of his dignity, and putting on such a garment as might best favour his flight, he stole out at the decuman gate, and took the road to Larissa, which city had hitherto shown great attachment to him. In the mean time Cæsar began the attack on the enemy's camp, which was vigorously defended by the cohorts Pompey had left to guard it; but they were at length forced to yield. Cæsar was not a little surprised, when, after having forced the entrenchments, he found the enemy's tents and pavilions richly adorned with carpets and hangings, their couches strewed with flowers, their tables ready spread, and sideboards set out with abundance of plate, bowls, and glasses, and some of them even filled with wine. So great was the confidence of Pompey's party, that they made preparations before hand for pleasures to be enjoyed after the victory, which they thought certain. In Pompey's tent, Cæsar found the box in which he kept his letters: but, with a moderation and magnanimity worthy of himself, he burnt them all, without reading one; saying, that he had rather be ignorant of crimes, than obliged to punish them.

The next day, when the dead were numbered, it appeared that Cæsar had scarce lost 200 men; among whom were about 30 centurions, whom Cæsar caused to be buried with great solemnity. He did particular honours to the body of Crastinus, who had begun the battle; and ordered his ashes to be deposited in a tomb, which he erected to his memory. On Pompey's side, the number of the dead amounted to 15,000 according to some, and to 25,000 according to others. Cæsar took 24,000 prisoners, eight eagles, and 180 ensigns.

PHARSALIA, an epic poem, composed by Lucan on the civil war between Pompey and Cæsar, and particularly on the victory of the latter over the former, of which we have given an account in the preceding article. It is a poem universally acknowledged to have great beauties and great defects; but we are the less capable of estimating its merit as a whole, that either time has deprived us of the last books, or its author has left it incomplete. "The subject of the Pharfalia (says an excellent critic) carries undoubtedly all the epic grandeur and dignity: neither does it want unity of object, viz. the triumph of Cæsar over the Roman liberty. In the choice of that subject, he thinks, however, that the author was not happy. The civil wars were too recent to admit in the description of them the embellishments of fiction and machinery. The fables of the gods mixed with the exploits of Cæsar and Pompey, instead of raising, would have diminished, the dignity of such well known facts." Another objection to the subject, perhaps more forcible than this, arises from the success of the war and the abilities of the generals. Lucan was a friend to liberty, and wished to raise the character of Pompey and Cato; but in spite of his utmost efforts, they are always eclipsed by the superior talents and consequent success of Cæsar. All his characters, however, are drawn

with spirit, and with uncommon regard to truth; and some of the speeches which he puts into the mouths of his heroes are equal for moral sublimity to any thing that is to be found in all antiquity.

"There are in the Pharfalia (continues the critic already quoted) several very poetical and spirited descriptions. But the author's chief strength does not lie either in narration or description. His narration is often dry and harsh; his descriptions are often overwrought, and employed too upon disagreeable objects. His principal merit consists in his sentiments, which are generally noble and striking, and expressed in that glowing and ardent manner which peculiarly distinguishes him. Lucan is the most philosophical and the most public-spirited poet of all antiquity. He was the nephew of the famous Seneca the philosopher; was himself a Stoic; and the spirit of that philosophy breathes throughout his poem. We must observe, too, that he is the only ancient epic poet whom the subject of his poem really and deeply interested. Lucan recounted no fiction. He was a Roman, and had felt all the direful effects of the Roman civil wars, and of that severe despotism which succeeded the loss of liberty. His high and bold spirit made him enter deeply into this subject, and kindle, on many occasions, into the most real warmth. Hence, he abounds in exclamations and apostrophes, which are almost always well timed, and supported with a vivacity and fire that do him no small honour.

"But it is the fate of this poet, that his beauties can never be mentioned, without their suggesting his blemishes also. As his principal excellency is a lively and glowing genius, which appears sometimes in his descriptions, and very often in his sentiments, his great defect in both is want of moderation. He carries every thing to an extreme. He knows not where to stop. From an effort to aggrandise his objects, he becomes tumid and unnatural: and it frequently happens, that where the second line of one of his descriptions is sublime, the third, in which he meant to rise still higher, is perfectly bombast. Lucan lived in an age when the schools of the declaimers had begun to corrupt the eloquence and taste of Rome. He was not free from the infection; and too often, instead of showing the genius of the poet, betrays the spirit of the declaimer; but he is, on the whole, an author of lively and original genius."

PHARUS, in botany: A genus of the hexandria order, belonging to the monœcia class of plants; and in the natural method ranking under the fourth order, *Gramina*. The male calyx is a bivalved uniflorous glume; the corolla, a bivalved glume; the female calyx the same with the male; the corolla an uniflorous, long, and wrapping glume. There is but one seed.

PHARYNX, in anatomy. See there, p. 708, 709.
PHASCUM, in botany: A genus of the order of musci, belonging to the cryptogamia class of plants. The anthera is operculated, with a ciliated mouth; the calyptrae are minute.

PHASEOLUS, the KIDNEY BEAN; a genus of the decandria order, belonging to the diadelphia class of plants. There is only one species; but of this there are many varieties. Those principally cultivated for the table are, 1. The common white, or Dutch kidney-bean.

Pharfalia
||
Phascolum.

Phaseolus, bean. 2. The smaller kidney-bean, commonly called the *Battersea kidney-bean*. And, 3. The upright sort, called the *tree kidney-bean*.

1. The first sort was some time ago propagated in England, and is still in Holland; it grows very tall, and requires long stakes and poles to climb on, and its beans are considerably broad; this makes them less saleable in the markets, people supposing them to be old because they are broad; and they are hence grown into disuse, though a much more valuable kind for eating than any other.

2. The second sort, or *Battersea bean*, is what is more universally cultivated; it never grows very tall, nor rambles far, and the air can easily pass between the rows, because of its moderate growth; and this makes it bear plentifully, and ripen well for the table. It is the best tasted bean, except the last.

3. The third, or *tree kidney-bean*, is also a plentiful bearer, and never rambles, but grows up in form of a shrub; but its beans are broader than the *Battersea* kind, and are not so well tasted.

They are well propagated from seeds, which are to be put into the ground in the latter end of March or beginning of April for an early crop: but these should have a warm situation and a dry soil; they must also be planted in a dry season. The manner of planting them is, to draw lines with a bough over the bed, at two feet and a half distance, into which the seeds are to be dropped out about two inches asunder; and the earth is to be drawn over them with the head of a rake, to cover them about an inch deep. In a week after sowing, the plants will appear, and the earth should be drawn up about their stalks as they rise up; for a few days after this they will require no further care, except to be kept clear from weeds, and, when the beans appear, to have them gathered twice a week, for if the beans are suffered to hang on too long, they not only become of no value, but they weaken the plant. The first crop of kidney-beans will continue a month in good order; and, to supply the table afterwards, there should be fresh sowings in March, April, May, and June; the last of which will continue till the frosts come to destroy them. Some raise their early crops on hot-beds; and this is to be done exactly in the same manner as the raising the early cucumbers.

A new species of *phaseolus*, apparently a very useful one, has been discovered by M. Moraney, "an inhabitant of Morne Rouge, dependent on the Cape;" we suppose Cape Francois of the island of St Domingo. In his search for plants, subservient to his collection of insects for the king's cabinet, he was overtaken by night, and he passed it in a cave, to which he had recourse for shelter. At its extremity he found beds of fossils, broken pieces of burnt earthen-ware, some tools and other things, which showed that this cave had formerly been the habitation of the natives. Near it he saw a climbing plant attached to some trees, with clusters of dry pods hanging from it. These he gathered, and on his return sowed the seed. Some months after, the plants grew tall and strong: they appeared to resemble a *phaseolus* known at Perpignan by the name of *caraguola*, and in the superb portfolios of the king by that of *phaseolus indicus, cochleato flore*, which produced many roots, not unlike the ma-

nioc. On examining the root after the pods were ripe, he found from three to eight roots of this kind. The force of the vegetation was wonderful; but dreading the deleterious effects of recent manure, he did not taste them, but subjected them to a chemical analysis, which proved nothing. After boiling them in water a little salted, he ventured to taste them, and found them moist, unctuous, and saccharine, not unlike potatoes. He made, after some hours trial, very good cassava with them, without being incommoded by the disagreeable fibres which are met with in the manioc during this operation. Since that time, biscuit and bread have been made from these roots by M. Lombert counsellor at the Cape. The plant has been found to be very common in the woods. It requires no peculiar management: its roots are in season when the pods blacken, and its fibres run in every direction, searching for nourishment through the clefts of rocks, and receiving the impression of the frost without injury. If the principal root is left, the plant shoots again and flourishes as before; but it is not yet ascertained whether it puts forth any new roots. The seeds are not alimentary when dressed, as if nature designed them only for propagating other plants. Every use which a farinaceous plant can supply, this new *phaseolus* has successfully answered; and the seeds in the hands of Messrs Heretier and Thouin will probably furnish a sufficient quantity for curiosity as well as use.

PHASES, in astronomy, from the Greek word *εφαση*, "to appear;" the several appearances or quantities of illumination of the moon, Venus, Mercury, and the other planets. See ASTRONOMY.

PHASGA, or PISCAB, (Moses), a mountain on the other side Jordan, joined to Abatim and Nebo, and running south to the mouth of the Arnon: from which Moses had a view of the promised land, and where he died, having before appointed Joshua his successor. Wells takes Pisgah and Nebo to be different names of one and the same mountain, a part or branch of the mountains Abarim, (Deut. xxxii. 49. compared with Deut. xxxiv. 1.) Or that the top of Nebo was peculiarly called *Pisgah*; or some other part of it, cut out in steps, as the primitive word denotes: and thus it is rendered by Aquila, by a Greek word signifying *cut out* (Jerome). There was also a city of this name, *id.*; and the adjoining country was in like manner called *Pisgah, id.*

PHASIANUS, in ornithology, a genus belonging to the order of gallinae. The cheeks are covered with a smooth naked skin.

Gibbons, in his Roman History, tells us, that the name *Phasianus* is derived from the river PHASIS, the banks of which is the native habitation of the pheasant. See PHASIS.

1. The gallus, or common dunghill cock and hen, *Dung-hill* with a compressed caruncle or fleshy comb on the top *cock*. of the head, and a couple of caruncles or wattles under the chin. The ears are naked, and the tail is compressed and erected. Of all other birds, perhaps this species afford the greatest number of varieties; there being scarce two to be found that exactly resemble each other in plumage and form. The tail, which makes such a beautiful figure in the generality of these birds, is yet found entirely wanting in others; and not only

Phases
||
Phasianus.

Pheasant the tail, but the rump also. The toes, which are usually four in all animals of the poultry kind, yet in a species of the cock are found to amount to five. The feathers, which lie so sleek and in such beautiful order in most of those we are acquainted with, are in a peculiar breed all inverted, and stand flung the wrong way. Nay, there is a species that comes from Japan, which instead of feathers seems to be covered over with hair.

It is not well ascertained when the cock was first made domestic in Europe; but it is generally agreed that we first had him in our western world from the kingdom of Persia. Aristophanes calls the cock the *Persian bird*; and tells us he enjoyed that kingdom before some of its earliest monarchs. This animal was in fact known so early even in the most savage parts of Europe, that we are told the cock was one of the forbidden foods among the ancient Britons. Indeed, the domestic fowl seems to have banished the wild one. Persia itself, that first introduced it to our acquaintance, seems no longer to know it in its natural form: and if we did not find it wild in some of the woods of India, as well as those of the islands in the Indian ocean, we might begin to doubt, as has been done with regard to sheep, in what form it first existed in a state of nature. But the cock is still found in the islands of Tinian, in many others of the Indian ocean, and in the woods on the coast of Malabar, in its ancient state of independence. In his wild condition, his plumage is black and yellow, and his comb and wattles yellow and purple. There is another peculiarity also in those of the Indian woods; their bones, which, when boiled with us, are white, as every body knows, in those are as black as ebony.

In their first propagation in Europe, there were distinctions then that now subsist no longer. The ancients esteemed those fowls whose plumage was reddish as invaluable; but as for the white, it was considered as utterly unfit for domestic purposes. These they regarded as subject to become a prey to rapacious birds; and Aristotle thinks them less fruitful than the former. Indeed, his division of those birds seems taken from their culinary uses; the one sort he calls *generous and noble*, being remarkable for fecundity; the other sort, *ignoble and useless*, from their sterility. These distinctions differ widely from our modern notions of generosity in this animal; that which we call the *game-cock* being by no means so fruitful as the ungenerous dung-hill cock, which we treat with contempt. The Athenians had their cock-matches as well as we; but it is probable they did not enter into our refinement of choosing out the most barren of the species for the purposes of combat.

However this be, no animal in the world has greater courage than the cock when opposed to one of his own species; and in every part of the world where refinement and polished manners have not entirely taken place, cock-fighting is a principal diversion. In China, India, the Philippine islands, and all over the East, cock-fighting is the sport and amusement even of kings and princes. With us it is declining every day; and it is to be hoped it will in time become only the pastime of the lowest vulgar. See the article *Cock-pit*.

The cock claps his wings before he sings or crows. His sight is very piercing; and he never fails to cry in a

peculiar manner, when he discovers any bird of prey Pheasant, in the air. His extraordinary courage is thought to proceed from his being the most falacious of all other birds whatsoever. A single cock suffices for ten or a dozen hens; and it is said of him that he is the only animal whose spirits are not abated by indulgence. But then he soon grows old; the radical moisture is exhausted; and in three or four years he becomes utterly unfit for the purposes of impregnation. "Hens also (to use the words of Willoughby), as they for the greatest part of the year daily lay eggs, cannot suffice for so many births, but for the molt part after three years become effete and barren: for when they have exhausted all their seed-eggs, of which they had but a certain quantity from the beginning, they must necessarily cease to lay, there being no new ones generated within."

The hen seldom clutches a brood of chickens above once a season, though instances have been known in which they produced two. The number of eggs a domestic hen will lay in the year are above 200, provided she be well fed and supplied with water and liberty. It matters not much whether she be trodden by the cock or no; she will continue to lay, although the eggs of this kind can never by hatching be brought to produce a living animal. Her nest is made without any care, if left to herself: a hole scratched into the ground, among a few bushes, is the only preparation she makes for this season of patient expectation. Nature, almost exhausted by its own fecundity, seems to inform her of the proper time for hatching, which she herself testifies by a clucking note, and by discontinuing to lay. The good housewives, who often get more by their hens laying than by their chickens, often artificially protract this clucking season, and sometimes entirely remove it. As soon as a hen begins to cluck, they stint her in her provisions; which, if that fails, they plunge her into cold water; this, for the time, effectually puts back her hatching; but then it often kills the poor bird, who takes cold and dies under the operation.

If left entirely to herself, the hen would seldom lay above 20 eggs in the same nest, without attempting to hatch them: but in proportion as she lays, her eggs are removed; and she continues to lay, vainly hoping to increase the number. In the wild state, the hen seldom lays above 15 eggs; but then her provision is more difficultly obtained, and she is perhaps sensible of the difficulty of maintaining too numerous a family.

When the hen begins to sit, nothing can exceed her perseverance and patience; she continues for some days immovable; and when forced away by the importunities of hunger, she quickly returns. Sometimes also her eggs become too hot for her to bear, especially if she be furnished with too warm a nest within doors, for then she is obliged to leave them to cool a little: thus the warmth of the nest only retards incubation, and often puts the brood a day or two back in the shell. While the hen sits, she carefully turns her eggs, and even removes them to different situations; till at length, in about three weeks, the young brood begin to give signs of a desire to burst their confinement. When by the repeated efforts of their bill, which serves like a pioneer on this occasion, they have broke themselves a passage through the shell, the hen still continues to sit

Phasianus. till all are excluded. The strongest and best chickens generally are the first candidates for liberty; the weakest come behind, and some even die in the shell. When all are produced, she then leads them forth to provide for themselves. Her affection and her pride seem then to alter her very nature, and correct her imperfections. No longer voracious or cowardly, she abstains from all food that her young can swallow, and flies boldly at every creature that she thinks is likely to do them mischief. Whatever the invading animal be, she boldly attacks him; the horse, the hog, or the mastiff. When marching at the head of her little troop, she acts the commander; and has a variety of notes to call her numerous train to their food, or to warn them of approaching danger. Upon one of these occasions, the whole brood have been seen to run for security into the thickest part of an hedge, while the hen herself ventured boldly forth, and faced a fox that came for plunder.

Ten or twelve chickens are the greatest number that a good hen can rear and clutch at a time; but as this bears no proportion to the number of her eggs, schemes have been imagined to clutch all the eggs of an hen, and thus turn her produce to the greatest advantage. By these contrivances it has been obtained, that a hen that ordinarily produces but 12 chickens in the year, is found to produce as many chickens as eggs, and consequently often above 200. This contrivance is the artificial method of HATCHING chickens in stoves, as is practised at Grand Cairo; or in a chemical laboratory properly graduated, as has been effected by Mr Reaumur. At Grand Cairo, they thus produce 6000 or 7000 chickens at a time; where, as they are brought forth in their mild spring, which is warmer than our summer, the young ones thrive without clutching. But it is otherwise in our colder and unequal climate; the little animal may without much difficulty be hatched from the shell, but they almost all perish when excluded. To remedy this, Reaumur has made use of a woollen hen, as he calls it; which was nothing more than putting the young ones in a warm basket, and clapping over them a thick woollen canopy.

Capons may very easily be taught to clutch a fresh brood of chickens throughout the year; so that when one little colony is thus reared, another may be brought to succeed it. Nothing is more common than to see capons thus employed; and the manner of teaching them is this: First the capon is made very tame, so as to feed from one's hand; then, about evening, they pluck the feathers off his breast, and rub the bare skin with nettles; they then put the chickens to him, which presently run under his breast and belly, and probably rubbing his bare skin gently with their heads, allay the stinging pain which the nettles had just produced. This is repeated for two or three nights, till the animal takes an affection to the chickens that have thus given him relief, and continues to give them the protection they seek for: perhaps also the querulous voice of the chickens may be pleasant to him in misery, and invite him to succour the distressed. He from that time brings up a brood of chickens like a hen, clutching them, feeding them, clucking, and performing all the functions of the tenderest parent. A capon once accustomed to this service, will not give over; but when one brood is grown up, he may have another nearly

hatched put under him, which he will treat with the same tenderness he did the former.

The cock, from his salaciousness, is allowed to be a short-lived animal; but how long these birds live, is left to themselves, is not yet well ascertained by any historian. As they are kept only for profit, and in a few years become unfit for generation, there are few that, from mere motives of curiosity, will make the tedious experiment of maintaining a proper number till they die. Aldrovandus hints their age to be 10 years; and it is probable that this may be its extent. They are subject to some disorders; and as for poisons, besides nux vomica, which is fatal to most animals except man, they are injured, as Linnæus asserts, by elderberries; of which they are not a little fond.

Of this species Mr Latham enumerates no less than 13 varieties, beginning with the wild cock, which is a third less in the body than the domestic cock. This variety he imagines to be the original stock from whence all our domestic varieties have sprung. They appear to be natives of the forests of India. There are but few places, however, as Mr Latham goes on to observe, where the different voyagers have not met with cocks and hens, either wild or tame; and mention has been particularly made of finding them at St Jago, Pulo Condore, Isle of Timor, Philippine and Molucca Isles, Sumatra and Java, New Guinea, Tinian, and most of the Isles of the South Seas.—Those of Pulo Condore are very much like our own, but considerably less, being only of the size of a crow. The cocks crow like ours, but their voices are much more small and shrill.—*Damp. Voy.* vol. i. p. 392.—Two wild ones were shot there by our last voyagers.—*Ellis's Narr.* ii. p. 340. Those of Sumatra and Java are remarkably large, and are called the *St Jago breed*. The cock is so tall as to peck off a common dining-table. When fatigued, he sits down on the first joint of the leg; and is then taller than the common fowls. *Hist. Sumatr.* p. 98. They are found in New Guinea, but not in great plenty.—*Farr. Voy.* p. 105. The fowls which were met with wild at Tinian “were run down without much trouble, as they could scarce fly farther than 100 yards at a flight.”—*Anson's Voy.* p. 416. Forster observes, that they are plenty at Easter, Society, and Friendly Isles: at the two last they are of a prodigious size. They are not uncommon at the Marquesas, Hebrides, and New Caledonia; but the Low Isles are quite destitute of them.—See *O'f.* p. 193.—Ducks and poultry are numerous in the Sandwich Isles.—*Cook's Journal,* p. 229. In respect to Europe, little need be said, as varieties without end are everywhere seen, and their manners fully known to every one. It is observed, however, that they breed most freely in the warmer situations. In the very cold regions, though they will live and thrive, they cease to multiply. They are not found to breed in the northern parts of Siberia; and in Greenland are only kept as rarities.—*Faun. Groen.* On the whole, it seems quite unnecessary to enlarge further on a subject well known to every body. They are so common, that every one who wishes to be once acquainted with their nature and manners, has the means of such knowledge in his power. Those who wish for minuter descriptions, we must refer to the authors

Phasianus who have professedly written on the subject; for the varieties which we have already mentioned, we refer to Mr Latham.

Pheasants. 2. The motmot, or Guinea pheasant, is brownish, somewhat red below, with a wedge-like tail, and wants spurs. 3. The colchicus is red, with a blue head, a wedge-shaped tail, and papillous cheeks. It is a native of Africa and Asia. 4. The argus is yellowish, with black spots, a red face, and a blue crest on the back part of the head. It is found in Chinese Tartary. 5. The pisinus has a yellowish crest, a red breast, and a wedge-shaped tail. It is a native of China. 6. The nothemerus is white, with a black crest and belly, and a wedge-shaped tail. It is a native of China.

Mr Latham enumerates nine different species of pheasants, and of the common pheasant he reckons six varieties. The first which he describes is the superb pheasant. This bird Linnaeus described from the various representations of it painted on paper-hangings and China ware; and farther confirmed by a figure and description in a Chinese book which came under his inspection.

Latham's Synopsis. "We have lately seen (says Latham) a drawing of the tail feather of a bird of the pheasant kind, which measured above six feet in length, and which, it is probable, must have belonged to some bird not hitherto come to our knowledge. The drawing is in the possession of Major Davies, who took it from the original feather; two of which were in the possession of a gentleman of his acquaintance, and were brought from China. They are exactly in shape of the two middle feathers of the painted pheasant; the general colour is that of a fine blue grey, margined on the sides with a rufous cream colour, and marked on each side the shaft with numerous bars of black; between 70 and 80 bars in all; those on the opposite sides of the shaft seldom corresponding with each other.

"The argus, though it be a native of China, is very commonly found in the woods of Samatra, where it is called *ayow*. It is found extremely difficult to be kept alive for any considerable time after catching it in the woods; never for more than a month. It seems to have an antipathy to the light, being quite inanimate in the open day; but when kept in a dark place, it appears perfectly at ease, and sometimes makes its note or call, from which it takes its name; and which is rather plaintive, and not harsh like that of a peacock. The flesh resembles that of the common pheasant."

Mr Latham observes, that the common pheasant is now found in a state of nature in almost the whole of the Old Continent. They sometimes (he says) come into farm yards near woods, and produce cross breeds with common hens. He then says, "M. Salerne remarks, that the hen-pheasant, when done laying and sitting, will get the plumage of the male, and after that become so little respected by him, as to be treated with the same incivility as he would show to one of his own sex. He mentions this as a new observation; but it is far more common than may be generally supposed, and had been long before mentioned by Edwards, who gave for example one kept in the menagerie of the duke of Leeds; and remarks, that this change is most likely to happen when in a con-

finer state. The circumstance of the hen acquiring the plumage of the cock after a certain time is not confined to the pheasant: the instance of the pea-hen belonging to Lady Tynte, now in the Leverian Museum, evinces the contrary, which, after having many broods, got much of the fine plumage of the cock, with the addition even of the fine train feathers. The female also of the rock manakin is said to get the plumage of the opposite sex after a number of years; and perhaps, if observed hereafter, this may be found to be the case with many other species. A gentleman of my acquaintance (continues our author), dead long since, who used to keep these birds for his amusement, observed the same to me: and the ingenious Mr J. Hunter has a well drawn up paper in the Philosophical Transactions* to the same purport; but, in addition to this, I am well informed, that it does not always require mature age to give the hen-pheasant the appearance of the male, as sometimes young birds will be adorned with his fine plumage. I will not say how this happens, and whether it may be peculiar to this species to grow barren (if that be the reason) sooner than any other of the gallinaceous tribe; but I am assured that several of these spurless, cock-like hens, have proved on eating to be young birds, from their juiciness and delicacy of flavour."

One of the varieties which our author remarks under this species, he calls the *Hybridal pheasant*, which is a mixed breed between the pheasant and cock; one of which is in the Leverian Museum. The two last species which our author describes, is the parraka and courier.

The parraka is about the size of a small fowl, resembling it in the bill, legs, and body. Its length is 23 inches. The colour of the bill is dark rufous; the eyes are brown, the general colour of the plumage is a deep brown on the back, and fulvous under the belly: the top of the head is fulvous, and the feathers are somewhat long, but not so much as to form a real crest; the wings are short; the webs of some of the quills are somewhat rufous; the tail consists of 12 feathers, is even at the end, about a foot in length, and is, for the most part, carried pendant; the legs are of a dark rufous, inclining to black; the claws are like those of a fowl.

"It is peculiar (says Mr Latham) in its internal structure in respect to the windpipe; which, instead of entering directly the breast, as in most birds, passes over the side of the left clavicle, and on the outside of the fleshy part of the breast, being covered only by the skin, then taking a turn upwards, passes over the right clavicle into the breast, and is distributed through the lungs in the usual way. The female has not this circumvolution of the windpipe. The hannequaw, mentioned by Bancroft, is probably the same bird. He says that it is black, roosts in trees, and may be heard early in the morning, distinctly, but hoarsely, repeating the word *hannequaw* (easily mistaken for *parrequaw*) very loud. These are found in the unfrequented woods of the internal parts of Cayenne, Guiana, and many parts of South America. At sun-rise they set up a very loud cry, which is thought to be the loudest of all birds in the new world; at which time the eyes appear red, as does a small skin under the breast, which is not at all seen, except when the bird

Phasianus. bird makes such exertions, or is angry. This cry is very like the word *parraquaw*; and is repeated many times together; and often many cry at once, or answer one another, but most in breeding-time, which is twice in the year; at each time laying from four to six eggs; making the nest in low branches or stumps of trees, and behaving with their chickens in the same manner as hens. They feed on grain, seeds, and herbs; but feed the young in the nest with worms and small insects. These, with many other birds, inhabit the woods by day, coming out into the open savannas morning and evening to feed; at which times they are chiefly killed by the natives and near inhabitants. They may be brought up tame; and their flesh is much esteemed.

"The courier pheasant is but very imperfectly described by Fernandez; and is said to be 13 inches long. The general colour of the plumage is white, inclined to fulvous; about the tail they are black, mixed with some spots of white; the tail itself is long, and of a green colour, reflecting in some lights like the feathers of a peacock: the wings are short. This species inhabits the hotter parts of Mexico; flies slow; but is recorded to outrun the swiftest horse*."

* *Hist. des Indes*. Pheasants were originally brought into Europe from the banks of the Phasis, a river of Colchis, in Asia Minor; and from whence they still retain their name. Next to the peacock, they are the most beautiful of birds as well for the vivid colour of their plumes as for their happy mixtures and variety. It is far beyond the power of the pencil to draw any thing so glossy, so bright, or points so finely blending into each other. We are told, that when Cræsus, king of Lydia, was seated on his throne, adorned with royal magnificence and all the barbarous pomp of eastern splendor, he asked Solon if he had ever beheld any thing so fine? The Greek philosopher, no way moved by the objects before him, or taking a pride in his native simplicity, replied, That after having seen the beautiful plumage of the pheasant, he could be astonished at no other finery.

These birds, tho' so beautiful to the eye, are not less

delicate when served up to the table. Their flesh is considered as the greatest dainty; and when the old physicians spoke of the wholesomeness of any viand, they made their comparison with the flesh of the pheasant. However, notwithstanding all these perfections to tempt the curiosity or the plate, the pheasant has multiplied in its wild state.

A spirit of independence seems to attend the pheasant even in captivity. In the woods, the hen-pheasant lays from 18 to 20 eggs in a season; but in a domestic state, she seldom lays above 10. In the same manner, when wild, she hatches and leads up her brood with patience, vigilance, and courage; but when kept tame, she never fits well, so that a hen is generally her substitute upon such occasions: and as for leading her young to their food, she is utterly ignorant of where it is to be found; and the young birds starve, if left solely to her protection. The pheasant, therefore, on every account, seems better left at large in the woods than reclaimed to captivity. Its fecundity when wild is sufficient to stock the forest; its beautiful plumage adorns it; and its flesh retains a higher flavour from its unlimited freedom.

However, it has been the aim of late to take these birds once more from the woods, and to keep them in places fitted for their reception. Like all others of the poultry kind, they have no great sagacity, and suffer themselves easily to be taken. At night they roost upon the highest trees of the wood; and by day they come down into the lower brakes and bushes, where their food is chiefly found. They generally make a kind of flapping noise when they are with the females; and this often apprises the sportsman (A) of their retreats. At other times he traces them in the snow, and frequently takes them in springs. But of all birds they are shot most easily; as they always make a whirring noise when they rise, by which they alarm the gunner, and being a large mark and flying very slow, there is scarce any missing them.

When these birds are taken young into keeping, they become as familiar as chickens: and when they are designed for breeding, they are put together in a yard,

(A) Pheasants may be taken in a variety of ways. One method is, to be well acquainted with their haunts and breeding places; which are generally young, thick, and well grown coppices, free from the disturbances of cattle and without a path-way through them; for they are timorous birds. When their haunts are discovered, it will next be necessary to find out where the brood is. And here it is to be remarked, that pheasants come out of the wood three times a-day to feed in green corn, fresh pastures, or such like places. The times of coming out are in the morning soon after sunrise, at noon, and at sunset. The sides of the wood where they may be supposed to come out ought then to be carefully watched, and the young ones will be seen following the female, as a flock of chickens follow the hen. The wood ought also to be watched in the evenings, when the noise of the cock and hen calling the young ones together will soon be heard; and the sportsman must then endeavour to get as near as he can to the place, and being very still and silent, he may observe their numbers and disposition, and learn how to spread his net so as most easily to take the whole brood; but if by the least motion they discover him, they will all take to their legs, and run to a great distance; for they seldom rise on the wing, except when very close frightened. By practice some people have become able to imitate the voice of the old pheasant, so as to be able to call the young ones together to any place that he pleases, when the haunts are once found out, and by this means they are easily led into the nets.—The best time for using this call is in the morning or evening; and the note imitated should be that by which they are called out to feed; indeed, by learning to imitate the other notes, they may be brought together at any time of the day. The sportsman who can make this call, must shelter himself in some close place, and begin very softly at first; then, if none are near enough to be within hearing, he is gradually to raise it louder and louder, and at length he will be answered as loud, if any are within hearing, though at a considerable distance;

Phasianus. yard, five hens to a cock; for this bird, like all of the poultry kind, is very falacious. In her natural state the female makes her nest of dry grass and leaves: the same must be laid for her in the pheasantry, and she herself will sometimes properly dispose them. If she refuses to hatch her eggs, then a common hen must be got to supply her place, which task she will perform with perseverance and success. The young ones are very difficult to be reared (B); and they must be supplied with ants-eggs, which is the food the old one leads them to gather when wild in the woods. To make these go the farther, they are to be chopped up with curds or other meat; and the young ones are to be fed with great exactness, both as to the quantity and the time of their supply. This food is sometimes also to be varied; and wood-lice, earwigs, and other insects, are to make a variety. The place where they are reared must be kept extremely clean; their water must be changed twice or thrice a-day; they must not be exposed till the dew is off the ground in the morning, and they should always be taken in before sunset. When they become adult, they very well can shift for themselves; but they are particularly fond of oats and barley.

In order to increase the breed, and make it still more valuable, Longolius teaches us a method that appears very peculiar. The pheasant is a very bold bird when first brought into the yard among other poultry, not sparing the peacock, nor even such young cocks and hens as it can master; but after a time it will live tamely among them, and will at last be brought to couple with a common hen. The breed thus produced take much stronger after the pheasant than the hen; and in a few successions, if they be let to breed with the cock-pheasant (for the mixture is not barren), there will be produced a species more tame, stronger, and more prolific; so that he adds, that it is strange why most of our pheasantries are not stocked with birds produced in this manner.

The pheasant, when full grown, seems to feed indifferently upon every thing that offers. It is said by a French writer, that one of the king's sportsmen shooting at a parcel of crows that were gathered round a dead carcase, to his great surprize, upon coming up, found that he had killed as many pheasants as crows. It is even asserted by some, that such is the carnivorous disposition of the bird, that when several of them are put together in the same yard, if one of them

stance; whereas, if he should set up the call too loud at first, and any of the birds should happen to be very near, they would be frightened away.

When a pheasant answers, the sportsman is to creep nearer and nearer, still calling, though not so loud; and he will still be answered, till at length he will be led by the bird's voice within sight of it. Then he is to spread his net, and to begin to call again, keeping in some close and well sheltered place behind the net, in this place he is to call till the bird approaches; and when he has drawn it under the net, he is to appear suddenly, and the bird, rising up, will thus be caught.

There is another method of taking pheasants much quicker than that we have just described, viz. the having a live cock-pheasant to use as a snare: this bird is to be fixed under the net, and by his crowing he will soon entice others in. The sportsman must lie concealed; and when another pheasant comes in, he is to draw the net over him. Many people take pheasants in springes or horse-hair snares: to succeed in this, it will be necessary to be careful in searching out their haunts, and the places by which they go out of the woods into the fields. When these are discovered, a peg must be fixed in the ground at each, and at each peg two springes must be laid open; the one to take in the legs, and the other the head. When the springes are set, the sportsman must go into the woods, and get behind the birds in order to fright them with some little noise, such as shall not be enough to raise them to the wing, but only to set them a-running. They will naturally make their way out of the wood, through their accustomed passages, and be then caught in the springes.

There is another method of taking these birds in winter, provided there be no snow. This must be done with a net made in the form of a casting net, but with wider meshes; they may indeed be five inches wide. Some peas or wheat are to be taken out; and the path of the pheasants being discovered, which may easily be done by their dung, a pint or thereabout of corn is to be thrown down in the path in a place marked, so that the sportsman can come to it again. This must be done for some days, till at length the pheasants will expect it every day regularly; and all of them that frequent the place are brought together to feed there, and then the net is to be fixed over the place, its top being tied up to some bough of a tree, and its bottom fixed down all around, except in one place, where the walk of the pheasants lies. In this place it must be raised in the form of an arch, and the entrance must be lined with several rods of hazel; the thick ends of which are to be tied to the net, and the thin ones let into the space covered by it; and thus the pheasants will easily get in by parting the small ends of the sticks, as fish into a wheel, but they will not easily get out again. The nets are to be dyed of a russet colour, by laying them in a tan-pit; and they must, when planted for this purpose, be covered with boughs, so that the birds do not discover them, and then they will easily run into them, and be all taken at once.

(B) The pheasant is so nearly allied to our common poultry that this assertion may appear odd: it is nevertheless true; and the principal cause may be, that their proper food is not known, or not sufficiently inquired into. They feed voraciously on ants and various other insects; and it is said, that when the mustiness of corn or want of cleanliness in their apartments has made them sick, a repast of ants has recovered them. When these fail, millepedes and earwigs together answer as an excellent medicine, along with their common food (corn,) which must be very sweet and clean. These birds are very fullen, and when coupling time is over, they are seldom found more than one in a place.

Phafis them happens to fall sick, or seems to be pining, all the rest will fall upon, kill, and devour it. Such is the language of books; those who have frequent opportunities of examining the manners of the bird itself, know what credit ought to be given to such an account.

Decline and
Fall of the
Roman
Empire.

PHASIS, a river which falls into the Euxine sea about 700 miles from Constantinople. "From the Iberian Caucasus (says Gibbon), the most lofty and craggy mountains of Asia, that river descends with such oblique vehemence, that in a short space it is traversed by 120 bridges. Nor does the stream become placid and navigable till it reaches the town of Sarapana, five days journey from the Cyrus, which flows from the same hills, but in a contrary direction, to the Caspian lake. The proximity of these rivers has suggested the practice, or at least the idea, of wafting the precious merchandise of India down the Oxus, over the Caspian, up the Cyrus, and with the current of the Phafis into the Euxine and Mediterranean seas. As it successively collects the streams of the plain of Colchos, the Phafis moves with diminished speed, tho' accumulated weight. At the mouth it is 60 fathoms deep, and half a league broad; but a small woody island is interposed in the midst of the channel: the water, so soon as it has deposited an earthy or metallic sediment, floats on the surface of the waves, and is no longer susceptible of corruption. In a course of 100 miles, 40 of which are navigable for large vessels, the Phafis divides the celebrated region of Colchos or Mingrelia, which, on three sides, is fortified by the Iberian and Armenian mountains, and whose maritime coast extends about 200 miles, from the neighbourhood of Trebizond to Dioscurias and the confines of Circassia. Both the soil and climate are relaxed by excessive moisture: 28 rivers, besides the Phafis and his dependent streams, convey their waters to the sea; and the hollowness of the ground appears to indicate the subterraneous channels between the Euxine and the Caspian."

PHASMATA, in physiology, certain appearances arising from the various tinctures of the clouds by the rays of the heavenly bodies, especially the sun and moon. These are infinitely diversified by the different figures and situations of the clouds, and the appulses of the rays of light; and, together with the occasional flashings and shootings of different meteors, they have, no doubt, occasioned those prodiges of armies fighting in the air, &c. of which we have such frequent accounts in most sorts of writers. See 2 Maccab. xi. 8. Melancth. Meteor. 2. Shel. de Comet. ann. 1618.

Kircher and Schottus have erroneously attempted to explain the phenomenon from the reflection of terrestrial objects made on opaque and congealed clouds in the middle region of the air, which according to them, have the effect of a mirror. Thus, according to these authors, the armies pretended by several historians to have been seen in the skies, were no other than the reflection of the like armies placed on some part of the earth. See Hist. Acad. Roy. Scienc. ann. 1726, p. 405, & seq.

PHASSACHATES, in natural history, the name of a species of agate, which the ancients, in its various appearances, sometimes called *leucachates* and *perileucos*.

THEASANT, in ornithology. See PHASIANUS.

Purvis int's eye, or Bird's-eye. See ADONIS.

PHEBE, a deaconess of the port of Corinth, called *Cenchrea*. St Paul had a particular esteem for this holy woman; and Theodoret thinks the apostle lodged at her house for some time, while he continued in or near Corinth. It is thought he brought to Rome the epistle he wrote to the Romans, wherein she is commended and recommended in so advantageous a manner. He says (Rom. xvi. 1, 2.), "I commend unto you Phebe our sister, which is a servant of the church which is at Cenchrea; that ye receive her in the Lord, as becometh saints, and that ye assist her in whatsoever business she hath need of you; for she hath been a succourer of many, and of myself also." Some moderns have advanced a notion that Phebe was wife to St Paul; but none of the ancients have said any thing like it. It is thought, in quality of deaconess, she was employed by the church in some ministrations suitable to her sex and condition: as to visit and instruct the Christian women, to attend them in their sickness, and distribute alms to them.

PHEGOR, or **PEOR**, a deity worshipped at a very early period by the Midianites and Moabites, and probably by all the other tribes which then inhabited Syria. Much has been said concerning the functions of this god, and the rank which he held among the Pagan divinities (see *Baal-Peor*); and many conjectures have been formed concerning the origin of his name. Most of these seem to have no better foundation than the senseless dreams of the Jewish rabbies. **PHEGOR**, or **PEOR**, is undoubtedly the same with the Hebrew word *pechor*, which signifies *opened*, and probably refers to the prophetic influence always attributed to the solar deity, by which he *opened* or *discovered* things to come. Accordingly we find **PHEGOR** or **PEOR** generally joined to *Baal*, which was the Syrian and Chaldean name of the sun after he became an object of worship; hence *Baal-Phegor* must have been the sun worshipped by some particular rites, or under some particular character. What these were, a resolution of *Pechor* into its component parts may perhaps inform us. As this word, wherever it occurs in Scripture, has some relation to disflending or opening the mouth wide, it is probably compounded of **PHAN** the *mouth* or *face*, and **EHAR** *naked*. In those countries we know that the women wore veils; but it would appear, that in celebrating the rites of this deity they were unveiled. It seems even not improbable, that on these occasions the sexes danced promiscuously without their clothes; a practice which would naturally give birth to the licentious amours mentioned in the 25th chapter of the book of Numbers. If this be admitted, it will follow that *Phegor* was the sun presiding over the mysteries of Venus.

PELLANDRIUM, WATER-HEMLOCK; a genus of the digynia order, belonging to the pentandria class of plants. There are two species, one of which, viz. the aquaticum, is a native of Britain. This grows in ditches and ponds, but is not very common. The stalk is remarkably thick and dichotomous, and grows in the water. It is a poison to horses, bringing upon them, as Linneus informs us, a kind of palsy: which, however, he supposes to be owing not so much to the noxious qualities of the plant itself, as to those of an

Pleasant

Phellandrium.

Phengites
||
Phere-
crates.

insect which feeds upon it, breeding within the stalks, and which he calls *curculio parapteticus*. The Swedes give swine's dung for the cure. The seeds are sometimes given in intermittent fevers, and the leaves are by some added to discutient cataplasms. In the winter, the roots and stem, dissected by the influence of the weather, afford a very curious skeleton or network. Horses, sheep, and goats, eat the plant; swine are not fond of it; cows refuse it.

Hill's Hist.
of fossils,
p. 490.

PHENGITES, among the ancients, the name of a beautiful species of alabaster. It is a rude irregular mass, very lustrous and friable, but of a brightness superior to that of most other marbles, and excelling them all in transparency. The colour is an agreeable pale, yellowish, white, or honey colour; the yellowish is more intense in some places than in others, and sometime makes an obscure resemblance of veins. It is very weak and brittle in the mass; and when reduced to small pieces, may be easily crumbled between the fingers into loofs, but considerably large angular pieces, some perfect, others complex, irregular, or mutilated, and all approaching to a flat shape. The ancients were very fond of this species in public buildings; and the Temple of Fortune, built entirely of it, has long been celebrated. Its great beauty is its transparency, from which alone this temple was perfectly light when the doors were shut, though it was built without a window, and had no other light but what was transmitted through the stone its walls were built with. It was anciently found in Cappadocia, and is still plentiful there: we have it also in Germany and France, and in Derbyshire in Great Britain, and some other counties. It takes an excellent polish, and is very fit for ornamental works, where there is no great strength required. See AMETHYST.

PHENICE, a port of the island of Crete, to the west of the island. St Paul having anchored at Phenice, when he was carried to Rome (Acts xxvii. 12.), advised the ship's crew to spend the winter there, because the season was too far advanced.

PHENICIA. See PŒNOCIA.

PHEONS, in heraldry, the barbed heads of darts, arrows, or other weapons.

PHEOS, in botany, a name which Theophrastus, Dioscorides, and others, give to a plant used by fullers in dressing their cloths, and of which there were two kinds, a smaller called simply *phos*, and a larger called *hipposphos*. This plant is sometimes called *phleos*; and is thus confounded with a kind of marsh cudweed, or *gnaphalium*, called also by that name; but it may always be discovered which of the two plants an author means, by observing the sense in which the word is used, and the use to which the plant was put. The *phleos*, properly so called, that is, the cudweed, was used to stuff beds and other such things, and to pack up with earthen vessels to prevent their breaking; but the *phos*, improperly called *phleos*, only about cloths: this was, however, also called *stabe* and *empton*.

PHERECRATE, a Greek comic poet, was contemporary with Plato and Aristophanes. After the example of the ancient comedians, who never introduced upon the theatre imaginary but living characters, he acted his contemporaries. But he did not abuse the liberty which at that time prevailed upon the stage;

and laid it down as a rule to himself never to destroy the reputation of any person. Twenty-one comedies are attributed to him, of which there now only remain some fragments collected by Hertelius and Grotius. From these fragments, however, it is easy to discern, that Pherecrates wrote the purest Greek, and possessed that ingenious and delicate raillery which is called *attic urbanity*. He was author of a kind of verse called from his own name, *Pherecratick*. The three last feet were in hexameter verse, and the first of those three feet was always a spondee. This verse of Horace (for example, *Quamvis pontica finus*) is a Pherecratick verse. We find in Plutarch a fragment of this poet upon the music of the Greeks, which has been critically examined by M. Burette of the academy of inscriptions. See the 15th volume of the collection published by that learned society.

PHERECYDES, a native of Scyros, flourished about the year 560 before the Christian era, and was disciple of Pittacus, one of the seven wise men of Greece (see PITTACUS). He is said to have been the first of all the philosophers who has written on natural subjects and the essence of the gods. He was also the first, it is said, who held the ridiculous opinion, "that animals are mere machines." He was Pythagoras's master, who loved him as his own father. This grateful scholar having heard that Pherecydes lay dangerously ill in the island of Delos, immediately repaired thither, in order to give every necessary assistance to the old man, and to take care that no means should be left untried for the recovery of his health. His great age, however, and the violence of his disease, having rendered every prescription ineffectual, his next care was to see him decently buried; and when he had paid the last duty to his remains, and erected a monument to his memory, he set out again for Italy. Other causes have been assigned for the death of Pherecydes: some say he was eaten up by lice, and others that he fell headlong from the top of Mount Corycius in his way to Delphos. He lived to the age of 85 years, and was one of the first prose writers among the Greeks.

"Marvellous circumstances have been related of him, which only deserve to be mentioned, in order to show that what has been deemed supernatural by ignorant spectators may be easily conceived to have happened from natural causes. A ship in full sail was at a distance approaching its harbour; Pherecydes predicted that it would never come into the haven, and it happened accordingly: for a storm arose which sunk the vessel. After drinking water from a well, he predicted an earthquake, which happened three days afterwards. It is easy to suppose that these predictions might have been the result of a careful observation of those phenomena which commonly precede storms or earthquakes in a climate where they frequently happen.

"It is difficult to give in any degree an accurate account of the doctrines of Pherecydes; both because he delivered them, after the manner of the times, under the concealment of symbols; and because very few memoirs of this philosopher remain. It is most probable that he taught those opinions concerning the gods and the origin of the world which the ancient Grecian theologians borrowed from Egypt;" and of which the reader will find accounts in different articles

Phidias.

cles of this work. See EGYPT, METAPHYSICS, MYSTERY, MYTHOLOGY, and POLYTHEISM.

PHERETIMA, was the wife of Battus king of Cyrene, and the mother of Aretefilaus. After her son's death, she recovered the kingdom by means of Amasis king of Egypt, and to avenge the murder of Aretefilaus, she caused all his assassins to be crucified round the walls of Cyrene, and she cut of the breasts of the wives, and hung them up near the bodies of their husbands. It is said that she was devoured alive by worms; a punishment which according to some of the ancients, was inflicted by Providence for her unparalleled cruelties.

PHERON, was a king of Egypt, who succeeded Sesostris. He was blind; and he recovered his sight by washing his eyes, according to the directions of the oracle, in the urine of a woman who had never had any unlawful connections. He tried his wife first, but she appeared to have been faithless to his bed, and she was burnt with all those whose urine could not restore sight to the king. He married the woman whose urine proved beneficial.

PHIAL, a well-known vessel made of glass used for various purposes.

Leyden PHIAL, is a phial of glass coated on both sides with tin foil for a considerable way up the sides, of great use in electrical experiments. See ELECTRICITY, *passim*.

PHIDIAS, the most famous sculptor of antiquity, was an Athenian and a cotemporary of the celebrated Pericles; who flourished in the 83d Olympiad. This wonderful artist was not only consummate in the use of his tools, but accomplished in those sciences and branches of knowledge which belong to his profession, as history, poetry, fable, geometry, optics, &c. He first taught the Greeks to imitate nature perfectly in this way; and all his works were received with admiration. They were also incredibly numerous; for it was almost peculiar to Phidias, that he united the greatest facility with the greatest perfection. His Nemesis was ranked among his first pieces; it was carved out of a block of marble, which was found in the camp of the Persians after they were defeated in the plains of Marathon. He made an excellent statue of Minerva for the Pluteans; but the statue of this goddess in her magnificent temple at Athens, of which there are still some ruined remains, was an astonishing production of human art. Pericles, who had the care of this pompous edifice, gave orders to Phidias, whose prodigious talents he well knew, to make a statue of the goddess; and Phidias formed a figure of ivory and gold 39 feet high. Writers never speak of this illustrious monument of skill without raptures; yet what has rendered the name of the artist immortal, proved at that time his ruin. He had carved upon the shield of the goddess his own portrait and that of Pericles; and this was, by those that envied them, made a crime in Phidias. He was also charged with embezzling part of the materials which were designed for the statue. Upon this he withdrew to Elis, and revenged himself upon the ungrateful Athenians, by making for the Elians the Olympic Jupiter; a prodigy of art, and which was afterwards ranked among the seven wonders of the world. It was of ivory and gold; 60 feet high, and every way proportioned. "The majesty of the work did equal the majesty of the god (says Quintilian,) and its

beauty seems to have added lustre to the religion of the country." Phidias concluded his labour with a matter-piece; and the Elians, to do honour to his memory, erected, and appropriated to his descent, an office, which consisted in keeping clean the magnificent image.

PHIDITIA, in Grecian antiquity, feasts celebrated with great frugality at Sparta. They were held in the public places and in the open air. Rich and poor assisted at them equally, and on the same footing their design being to keep up peace, friendship, good understanding, and equality among the citizens great and small. It is said that those who attended this feast brought each a bushel of flour, eight measures of wine named *chora*, five minces of cheese, and as many figs.

PHILA, in mythology, one of the attributes of Venus, which distinguishes her as the mother of Love from *queen to love*.

PHILADELPHIA, in antiquity, were games instituted at Sardis to celebrate the union of Caracalla and Geta, the sons of Septimius Severus.

PHILADELPHIA, the capital of Pennsylvania, and present seat of the federal government, is situated in the temperate latitude of 39° 56' N. 75° 8' W. Long. It is built on the western bank of the Delaware, about 120 miles above where it flows into the Atlantic ocean; distant ninety seven miles south west from New York, and one hundred and two miles from Baltimore. The river at Philadelphia is about one mile wide, and the navigation is safe for ships of 1200 tons burden. The tide rises six feet perpendicular, flowing on at the rate of four miles in an hour, to the Falls near Trenton, which is about thirty miles higher up the country. Above that place the Delaware is passable only by boats and timber-rafts.

The ground plot of the city is an oblong square, about one mile north and south, and two miles east and west, lying in the narrowest part of the isthmus between the Delaware and Schuylkill rivers, about five miles in a right line above their confluence. This oblong was at first divided into thirty two streets, twenty three of which lie about north and south, and nine, which intersect the former at right angles, lie as near east and west. These streets form one hundred and eighty four squares of ground of different areas. The streets running east and west are named (except High-street near the middle of the city) from the trees found in the country on the arrival of the colony: Vine, Sassafras, Mulberry, High, Chestnut, Walnut, Spruce, Pine, and Cedar streets, and those running north and south from their numeral order, Front, Second, Third, Fourth, &c. to Broad-street, which is midway between the two rivers. In deeds and other descriptive writings which require exactness, these streets have the Delaware or Schuylkill prefixed to their numeral names, to distinguish to which they belong; as Delaware Second-street, &c.; but as there are very few buildings westward of Broad-street, this addition is never made in common conversation, but when they are named they are always understood to be Delaware front unless Schuylkill is added.

Of these High-street is one hundred feet, Broad-street one hundred and thirteen feet, Mulberry sixty feet, and all the others fifty feet wide. Within the improved parts of the city they are paved, in the

Philadel-
phia.

middle with pebble stones for carts and carriages which usually contain three-fifths of the whole breadth, and on each side with bricks for foot passengers. Between the brick and stone pavements are gutters paved with brick to carry off the water, and the footways are defended from the approach of carriages, by rows of posts placed without the gutters, at the distance of ten or twelve feet from each other.

Besides the forementioned main streets, there are many others not originally laid down in the plot; the most public of which are Water-street and Dock-street. Water-street is about thirty feet wide, running below the bank, at the distance of about forty feet eastward from the parallel to Front-street, extending from the north line of the city southward, to the bridge over the dock, which was formerly a draw-bridge, and retains that name in common use, although it was converted into a stone arch above thirty years since. From the bridge it is forty feet wide in a right line to Pine-street, and leaves a row of houses, without yards, on the bank, in its whole length, between it and Front-street.

Southward of Pine-street there is an offset of about eighty feet eastward, and, the street from thence to Cedar street is 45 feet wide, and called Penn-street.

Besides the division into streets, in order to regulate elections, the city and liberties are likewise parcelled into wards; the city, from Cedar to Vine-street, contains twelve wards; the liberties, on the north of the city, two; the district of Southwark two; Passyunk and Moyamensing, each one.

The magistracy consists of two branches: fifteen aldermen are chosen by the freeholders to continue in office for seven years; who choose a recorder from the citizens at large for seven years, and a mayor from their own number for one year. Thirty common-council men are chosen by the citizens at large, entitled to vote for representatives in assembly, to continue in office for three years; these were intended to form a balanced government upon the principle, that the choice by freeholders, and for a longer term would produce a more select body of aldermen, and that the citizens at large would choose characters fitter to represent and form the popular branch of city government. Eight aldermen and sixteen common-council men form a quorum or board to transact business, at which the mayor or recorder presides; they sit and deliberate together, but no act is legal, unless a majority of the aldermen, a majority of the common-council men present, and the mayor or recorder concur.

A city court is held by the mayor, recorder and aldermen four times a year, and holds cognizance of all crimes and misdemeanors committed within the city.

A court of aldermen having cognizance of debts above forty shillings, and not exceeding twenty pounds is held every week beginning on Monday morning, and sitting by adjournments until the business of the week is finished.

Each alderman has separate cognizance of debts, under forty shillings.

The number of inhabitants including the city and suburbs (including the district of Southwark and the compactly built part of the Northern Liberties, which to every purpose, (but as their governments) are considered as parts of the city, is found by the late census to be 42,400, there was then about 7000 houses, stores and workshops. The number has now increased

to about 9000, and there are at present a great number building. Hence if the number of inhabitants has increased in the same ratio as the houses, which is highly probable, the number of citizens may be estimated at about 55,000.

The buildings appropriated to public worship in the city and suburbs are in number 28, and are as follows:

Of the baptist church one, German Calvinist one, protestant episcopal church three, Friends meeting-houses five, of the German Lutherans two, Swedish Lutherans one, of the Hebrews one, of the Moravians one, of the Presbyterians of different denominations six, of the Roman Catholics three, and of the universalists one.

There are also lately erected two buildings by the Africans; the one denominated the African protestant episcopal church; in which the ministers of the episcopal churches occasionally officiate. The other is called the African methodist episcopal church.

The city is provided with a number of public and private charitable institutions; the principal of which are, the Pennsylvania hospital, the house of employment, commonly called the bettering-house; the Friends alms-house; Christ church hospital; the dispensary; the humane society; the Philadelphia library; seminaries of learning, &c.

The Pennsylvania hospital, the design of which was first suggested by the late Dr Thomas Bond, is supported partly by public grants and partly by private subscriptions; its present property amounts to a little above 30,000*l*. Six physicians chosen by the managers attend the hospital. Lately the assembly granted 10,000*l*. out of certain loan-office funds to enable the managers to make additions to the buildings agreeable to the original plan, and to comprize a lying-in and foundling hospital, as soon as a specific fund can be raised.

This institution has been extensively useful, and the conduct of the managers has done honour to their benevolence and integrity. The medical students pay for the privilege of attending the hospital practice, and this money the physicians have generously given for the purpose of founding a medical library, and to purchase Dr Chovet's preparations; by the addition of which to Dr Fothergil's valuable present, the institution without any expence to its funds, is possessed of the most useful and ornamental collection that was ever seen in America. The pay of those pupils exceeds 100*l*. per annum, which is amply sufficient to furnish the library with new books and to preserve the anatomical castings, &c.

The house of employment is under the direction of a board of managers and of the overseers, or guardians of the poor. This is a spacious, convenient building, where the poor of the city and liberties receive a comfortable maintenance; and those who are able to work are employed in some coarse useful manufactures. The managers of this house were incorporated in the year 1766, and were authorized to impose taxes to defray the necessary contingent expences.

The quaker's alms house, designed for the reception of the aged poor of that religious community, is placed under the superintendance of committees appointed from time to time by the monthly meetings of Philadelphia. Besides their contributions in common with the rest of their fellow-citizens to the sup-

Philadel-
phia.

Philadel- port of the infirm and indigent of the general mass, this christian society is concerned to make particular provision for their own poor: some of whom are admitted within these walls and receive all the assistance their several cases require.

The Philadelphia dispensary was established by and is wholly dependent on the contributions of a generous public for its continuance. It is under the direction of twelve managers, elected annually from among the subscribers. These managers provide the best medicines that can be procured, and appoint an apothecary, who gives constant attendance to prepare and distribute them to all the poor who apply. They likewise appoint six attending and four consulting physicians, whose business it is to visit the sick who are unable to go abroad, and to prescribe when called upon whatever medicines are delivered. It is necessary that patients who apply should produce a recommendation from some one of the subscribers; and every subscriber who contributes one guinea annually has the privilege of recommending two patients at a time.

Among all the exertions of active benevolence for which this metropolis is distinguished, perhaps there is no one calculated to become so extensive a blessing as this institution. Many are the instances of the poor who do not choose to apply for admittance into the Pennsylvania hospital, and who at the same time are too indigent to pay a physician for medicine and attendance. To prevent patients of this description from languishing under their complaints, was the benevolent intention of the Philadelphia dispensary: and so great, indeed, hath been the success of the institution, that for one year, from December 1789 to December 1790, 1892 patients were under the care of the board, of whom 1578 were cured, and 111 relieved.

Christ Church hospital is an endowment for aged women of the protestant episcopal church, made by Dr John Kearsley, formerly an eminent physician in this city; who bequeathed for this purpose, an estate chiefly landed, which he vested in the rector, churchwardens, and vestrymen of the united episcopal churches of Christ Church and St Peter's.

Since the endowment of this institution, it has received a considerable accession of property, by the gift of Mr Joseph Dobbins, a native of this city, now residing in Carolina; subject to an annuity during Mr Dobbins's life.

Dr Kearsley's will requires that the women belonging to this institution shall be supplied with meat, drink, and lodging; with necessary assistance in physic and surgery:—there are now nineteen on the foundation.

The Humane Society. This charter qualifies the society, as a body corporate, to meet on the first Wednesday in March, and then to choose twelve managers for the ensuing year, to superintend and direct in all cases that relate to the design of the institution. In order to spread their assistance as wide as their capital would admit of, they have purchased eighteen sets of instruments, the best adapted to take bodies out of the water, and eighteen boxes of medicines, &c. which, with printed directions how to use them, they have deposited under prudent persons, at all those places in and near the city where they were most likely to be useful.

Besides these principal establishments, there are ma-

ny others, more restricted in their design and usefulness; as the society for visiting the public prison, and alleviating the miseries of its unhappy tenants; a class of citizens, who, in times past, have been considered as the outcasts of society, incapable of reformation, and unworthy of pity.—The society to promote the abolition of slavery, and to befriend the free Africans, who stand in need of support in asserting their rights. The society for establishing Sunday schools, calculated to spread the knowledge of religion and useful learning among poor children.

Societies, some of which are incorporated, for the relief of the widows and children of the clergy, supported by the members of the particular community to which they belong; and various other associations. In short, so multiplied are the institutions of generosity and beneficence, public and private, that there is hardly a pressure under which the poor and stranger can suffer, but what will meet with some alleviation as soon as the case is sufficiently known.

The Philadelphia Library. This valuable collection of books was begun in the year 1731, with the trifling sum of 100*l.* raised by subscription among a few private gentlemen, the friends of science. In the year 1742, the stock had accumulated so much, and its utility was so generally recognized, that the company received a charter of incorporation. Since this latter period the collection has greatly increased, by an annual contribution of ten shillings from each member, and the occasional donations of generous individuals, at home and abroad. At present it contains more than twelve thousand volumes, besides a valuable philosophical apparatus. The rooms are open every day in the week, except Sunday, for the benefit of strangers as well as citizens. Such free access to so large a repository of knowledge, in every branch of science, cannot fail of being extensively useful. And perhaps it is to institutions of this kind which are established in all the considerable towns of America, that her citizens are in a great degree, indebted for their general information and improvement.

Under this head it is not amiss to take notice that the Loganian library, the most rare and valuable collection of books in the ancient languages which is to be found on the continent, has lately been removed to a room built for the purpose, adjoining to the city library. This mass of antiquity was bequeathed by the late James Logan, Esq. to the public; and cannot fail to add much to the gratification of those who have a taste to explore the tomes of ancient erudition.

Seminaries of learning. Of these the first in rank is the Pennsylvania university. This seminary was instituted by a special act of the legislature in the year 1779: and by another act in the year 1791, it was united with the old college, academy, and charitable schools of Philadelphia, and placed under the direction of one board, consisting of twenty four trustees, of whom the governor of the state for the time being, is always president ex officio.

The funds of this institution are about two thousand three hundred pounds per annum. The number of students in all the schools is about five hundred; of whom five-and-twenty are admitted annually to the honour of degrees. The library and philosophical apparatus which belong to the seminary are judiciously selected, and very respectable.

Philadel-
phia.

The faculty consist of a provost, who is professor of natural philosophy; a vice-provost, who is professor of moral philosophy; and professors of the Greek and Latin languages; of Mathematics; of English and belles lettres; of the German language; of anatomy, surgery, and midwifery; of the practice of physic; of the institutes, and clinical medicine; of chemistry; of anatomy, &c. of materia medica; of botany, and natural history; and of law.

The college of physicians. This society was formed in the year 1787, and obtained a charter in the year 1789. It was instituted with the laudable design of consulting in new and difficult cases, and introducing greater uniformity in practice. They hold their stated meetings on the first Tuesday in every month.

The museum, which Mr Peale has now brought to a degree of importance and perfection which would not have been looked for in the time, is highly ornamental and useful; and the many public and private institutions which abound in Philadelphia, at once announce its prosperity and contribute to the advantage and pleasure of its inhabitants.

American philosophical society.—The American philosophical society, for promoting useful knowledge, was formed in the year 1769, by the union of two societies, which had been instituted with similar views; viz. the advancement of useful knowledge.

One of these, styled, "The American philosophical society," was instituted in the year 1743, and, at the time of their union consisted of 127 members: the other styled, "The American society for promoting and propagating useful knowledge, held in Philadelphia;" was instituted in the year 1766, and at the time of their union consisted of 78 fellows, and 69 corresponding members.

The peculiar situation of Philadelphia, possessing, by means of the Delaware, all the advantages of an excellent seaport, and from its inland situation in the midst of an extensive and well settled country, admirably adapted to the internal trade both of Pennsylvania and the neighbouring states, has contributed greatly to the increase of its population and the extension of its commerce, the foundations of which were laid in the wisdom and moderation of its first founders. Placed in the midst of a plentiful country, its markets are amply supplied with all the necessaries and most of the luxuries of life.

There is not a place in America, or, perhaps, in Europe, which can boast of a better market of fresh provisions, than Philadelphia. Nothing affords a more impressive image of the number of the inhabitants, and the plenty with which they are supplied, than a walk through High street, on the morning of a market-day. Here is the principal market-place, which abounds, twice every week, (on Wednesdays and Saturdays) with the greatest plenty of butchers' meat, poultry, eggs, butter, flour, cheese, and vegetables. Butchers' meat, and vegetables, may be had at the same place, on any day of the seven, except Sunday. The clerks of the market, officers appointed by the corporation, attend on all the stated market-days, to detect frauds, prevent the sale of unwholesome provisions, discourage forestalling, and to preserve good order.

Provisions and house rents were very moderate till of late, when the arrival of great numbers of people from Europe and the West Indies, and the supplies of

Philadel-
phia.

provisions for the belligerent powers of Europe have greatly increased the rates of both.

The banks of North America, the United States, and Pennsylvania, all of which are in Philadelphia, have greatly contributed to facilitate and extend its commerce.

PHILADELPHIA, an ancient town of Turkey in Asia, in Natolia. It is seated at the foot of mount Tmolus, by the river Cogamus, from whence there is an exceeding fine view over an extensive plain. This place was founded by Attalus Philadelphus, brother of Eumenes.

It was very liable to earthquakes, which perhaps, arose from its vicinity to the region called *Catakekamene*. So severe were those earthquakes, that even the city walls were not secure; and so frequent were they, that these experienced daily concussions. The inhabitants, therefore, who were not numerous, lived in perpetual apprehension, and their constant employment was in repairs. In fact, so great were their fears, that their chief residence was in the country, the soil of which was very fertile. Such is Strabo's account of this place. In the year 1097, it was taken by assault by John Ducas the Greek general. It was without difficulty reduced also in the year 1109, under the same emperor. The Turks marched from the East with a design to plunder it and the maritime towns. The Emperor Mamul, in 1175, retired for protection from the Turks to this place. In 1309 it fell by lot to Caraman. In 1306 it was besieged by Alifaras, and considerably harassed; but was not taken. In 1391, this place alone refused to admit Bajazet; but it was at length forced to capitulate for want of provisions. It has been matter of surprize that this town was not totally abandoned; and yet it has survived many cities less liable to inconveniences; and is still an extensive place, tho' in its appearance it is poor and mean. Some remnants of its walls are still standing, but with large gaps. The materials of the wall are small stones strongly cemented. It is thick, lofty, and has round towers. Near this place, between the mountains, there is a spring of a purgative quality; it is much esteemed, and many people resort to it in the hot months. It tastes like ink, is clear, but tinges the earth with the colour of ochre. The famous wall which credulity has asserted to be made of human bones, stands beyond this and beyond the town. See the article next.

When Dr Chandler was there he tells us, "The Travels in Greece." The bishop of Philadelphia was absent; but the proto papas or chief-priest, his substitute, whom we went to visit, received us at his palace, a title given to a very indifferent house or rather a cottage of clay. We found him ignorant of the Greek tongue, and were forced to discourse with him by an interpreter in the Turkish language. He had no idea that Philadelphia existed before Christianity, but told us it had become a city in consequence of the many religious foundations. The number of churches he reckoned at 24, mostly in ruins and mere masses of wall decorated with painted saints. Only six are in a better condition, and have their priests. The episcopal church is large, and ornamented with gilding, carving, and holy portraits. The Greeks are about 300 families, and live in a friendly intercourse with the Turks, of whom they speak well. We were assured that the clergy and laity

Philadel-
phia.
Philadel-
phus.

laity in general knew as little of Greek as the protopapas; and yet the liturgies and offices of the church are read as elsewhere, and have undergone no alteration on that account.

"The Philadelphians are a civil people. One of the Greeks sent us a small earthen vessel full of choice wine. Some families beneath the trees by a rill of water, invited us to alight and partake of their refreshments. They saluted us when we met: and the aga or governor, on hearing that we were Franks, bade us welcome by a messenger.

"Philadelphia possessing waters excellent in dying, and being situated on one of the most capital roads to Smyrna, is much frequented, especially by Armenian merchants. The Greeks still call this place by its ancient name, but the Turks call it *Allahijur*. The number of inhabitants are about 7000 or 8000; of whom 2000 are supposed to be Christians. It is about 40 miles E. S. E. of Smyrna. E. Long. 28. 15. N. Lat. 38. 28.

PHILADELPHIA-STONES, a name which some authors have given to what is otherwise called *Christian bones*, found in the walls of that city. It is a vulgar error that these walls are built of bones; and the tradition of the country is, that when the Turks took the place, they fortified it for themselves, and built their walls of the bones of the Christians whom they had killed there. Dr Smyth, in one of his epistles, mentions this wall as an instance of Turkish barbarity. This idle opinion has gained credit merely from a loose and porous stone of the sparry kind, found in an old aqueduct, which is still in the wall. Sir Paul Rycaut brought home pieces of these stones, which even he supposed to have been bones, but they proved on examination to be various bodies, chiefly vegetable, incrusted over and preserved in a spar of the nature of that which forms incrustations in Knareborough spring, and other places with us. These bodies are often cemented together in considerable numbers by this matter, and their true shape lost in the congeries till a diligent and judicious eye traces them regularly.

PHILADELPHIAN-SOCIETY, in ecclesiastical history, an obscure and inconsiderable society of mystics. They were formed about the end of the last century by an English female fanatic, whose name was *Jane Leadley*. This woman seduced by her visions, predictions, and doctrines, several disciples, among whom were persons of learning. She believed that all dissensions among Christians would cease, and the kingdom of the Redeemer become a scene of charity and felicity, if Christians, disregarding the forms of doctrine or discipline of their several communions, would all join in committing their souls to the care of the internal guide, to be instructed, governed, and formed, by his divine impulse and suggestions. But she went farther than this: she even pretended a divine commission to proclaim the approach of this glorious communion of saints; and was convinced that the society established by herself was the true kingdom of Christ. One of her leading doctrines was, that of the final restoration of all intelligent beings to perfection and happiness.

PHILADELPHUS, in antiquity, was a title or surname born by several ancient kings; formed from the Greek, φίλος, "friend, lover," and αδελφός, "brother;" *q. d.* one who loves his brother or brethren. See *PROTEMY* and *EGYPT*.

PHILADELPHUS, the PIPE-TREE, or *Mock orange*; a genus of the monogynia order, belonging to the icofandria class of plants.

Philadel-
phus

Species 1. The coronarius, white syringe, or mock-Britain has been long cultivated in the gardens of country as a flowering shrub; it is not well known in what country it is to be found native. It rises seven or eight feet high; sending up a great number of slender stalks from the root. These have a grey bark, branch out from their sides, and are garnished with oval spear-shaped leaves. These last have deep indentures on their edges; their upper surface being of a deep green, but the under surface pale, with the taste of a fresh cucumber. The flowers are white, and come out from the sides and at the ends of the branches in loose bunches, each standing on a distinct foot stalk: they have four oval petals, which spread open, with a great number of stamina within, surrounding the style.

This shrub by its flowers makes a fine figure in May and June; for they are produced in clusters both at the end and from the sides of the branches. They are of a fine white colour, and exceedingly fragrant. The petals of which each is composed are large, and spread open like those of the orange; and then forming branches, which stand each on its own separate short footstalk, and being produced in plenty all over the shrub, both at once feast the eye and the smell: The eye, by the pleasing appearance it will then have; the smell, as the air at some distance will be replete with the odoriferous particles constantly emitted from those fragrant flowers. These flowers, however, are very improper for chimneys, water glasses, &c. in rooms; for in those places their scent will be too strong; and for the ladies in particular, often too powerful.

Diét. of
Planting
and Gar-
dening.

The double-flowering syringa, is a low variety of this species, seldom rising to more than a yard high. The description of the other belongs to this sort, except that the leaves and branches are proportionably smaller and more numerous, and the bark of the shoots of a lighter brown. It is called the *Double flowering syringa*, because it sometimes produces a flower or two with three or four rows of petals; whereas, in general, the flowers, which are very few, and seldom produced, are single. They are much smaller than those of the other; and you will not see a flower of any kind on this shrub oftener perhaps than once in five years. It is hardly worth propagating on this account; so that a few plants only ought to be admitted into a collection, to be ready for observation.

The dwarf syringa is still of lower growth than the other, seldom arising to more than two feet in height. The description of the first sort still agrees with this; only that the branches and leaves are still proportionally smaller and more numerous, and the bark is still of a lighter brown. It never produces flowers.

2. The nanus, with oval leaves somewhat indented, and double flowers, seldom rises above three feet high; the flowers come out singly from the sides of the branches, and have a double or treble row of petals of the same size and form as well as the same scent with the former; but this sort flowers very rarely, so is but little esteemed.

3. The inodorous, with entire leaves, is a native of Carolina, and as yet but little known in Europe. It rises with a shrubby stalk of about 16

Philadel-
phus,
Philæni,

fect in height, sending out slender branches from the sides opposite, garnished with smooth leaves sharped like those of the pear-tree, and standing on pretty long foot stalks. The flowers are produced at the ends of the branches; and are large, white, spreading open, with a great number of short stamina with yellow summits. This is called the *Cardina fyringa*, is the tallest grower by far of any sort of the fyringa, and makes the grandest show when in blow; though the flowers are destitute of smell.

The propagation of all the sorts is very easy: They are increased by layers, cuttings, or suckers. 1. The most certain method is by layers; for the young twigs being laid in the earth in the winter, will be good-rooted plants by the autumn following. 2. These plants may be increased by cuttings, which being planted in October, in a shady moist border, many of them will grow; though it will be proper to let those of the Carolina sort remain until spring, and then to plant them in pots, and help them by a little heat in the bed. By this assistance, hardly one cutting will fail. 3. They may be also increased by suckers: for all the sorts throw out suckers, though the Carolina fyringa the least of any. These will all strike root, and be fit for the nursery ground: nay, the double-flowering and the dwarf sorts are always increased this way; for these plants having stood five or six years, may be taken up and divided into several scores. All the plants, however, whether raised from layers, cuttings, or suckers should be planted in the nursery-ground to get strength, before they are set out for growth. They should be planted a foot asunder, and the distance in the rows should be two feet. After this they will require no other care than hoeing the weeds, until they have stood about two years, which will be long enough for them to stand there.

PHILÆNI, were two brothers, citizens of Carthage, who sacrificed their lives for the good of their country. At the time when the Carthaginians ruled over the greatest part of Africa, the Cyrenians were also a great and wealthy people. The country in the middle betwixt them was all sandy, and of an uniform appearance. There was neither river nor mountain to distinguish their limits; a circumstance which engaged them in a terrible and tedious war with one another. After their armies and fleets had been often routed and put to flight on both sides, and they had weakened one another pretty much; and fearing left by and by, some third people should fall upon the conquered and conquerors together, equally weakened, upon a cessation of arms they made an agreement, "that upon a day appointed deputies should set out from their respective homes, and the place where they met one another should be accounted the common boundary of both nations." Accordingly the two brothers called Philæni, sent from Carthage, made all dispatch to perform their journey. The Cyrenians proceeded more slowly. These last, perceiving themselves a little behind, and turning apprehensive of punishment at home for mismanaging the affair, charged the Carthaginians with retarding out before the time; made a mighty bustle upon it; and, in short, would rather choose any

thing than to go away outdone. But whereas the Carthaginians desired any other terms, provided only they were fair, the Greeks made this proposal to the Carthaginians, "either to be buried alive in the place which they claimed as the boundary to their nation; or that they would advance forward to what place they inclined upon the same condition." The Philæni accepting the offer, made a sacrifice of themselves and their lives to their country, and so were buried alive. The Carthaginians dedicated altars in that place to the memory of the two brothers. These altars, called *Aræ Philænorum*, served as a boundary to the empire of the Carthaginians, which extended from this monument to Hercules's Pillars, which is about 2000 miles, or, according to the accurate observations of the moderns, only 1420 geographical miles. It is Sallust who gives this account in his history of the Jugurthine war.

PHILANTHROPY is compounded of two Greek words which signify the love of mankind. It is therefore of nearly the same import with *benevolence* (A); and differs from *friendship*, as this latter affection subsists only between a few individuals, whilst *philanthropy* comprehends the whole species.

Whether man has an instinctive propensity to love his species, which makes him incapable of happiness but in the midst of society, and impels him to do all the good that he can to others, feeling their felicity an addition to his own, is a question that has been warmly debated among philosophers ever since metaphysics was studied as a science. With the opinions of the ancients we shall not, in this detached article, trouble our readers; but it would be unpardonable to pass without notice the different theories which on so interesting a subject have divided the moderns.

Hobbes, who believed, or pretended to believe, that right results from power, and that in society there is no other standard of justice than the law of the land, or the will of the supreme magistrate, built his opinions upon a theory of human nature in which philanthropy has no place. According to him, mankind, in the original state of nature, were wholly *selfish*. Each endeavoured to seize, by fraud or force, whatever he thought would contribute to his comfort; and as all had nearly the same wants, the inevitable consequence of this selfishness was universal war. We are taught indeed by the same philosopher, that, in a series of ages, mankind discovered the miseries of this state of nature; and therefore, upon the same basis of universal selfishness, formed societies over which they placed supreme governors for the purpose of protecting the weak against the violence of the strong. He does not, however, explain how men, whose angry and selfish passions were thus excited to the utmost against each other, could enter upon this friendly treaty; or, supposing it formed, how the ignorant multitude were induced to pay obedience to the more enlightened few. Clogged with this and other insurmountable difficulties, his philosophy of human nature soon fell into merited contempt; but about the *origin* of philanthropy those who united in opposition to him still thought very differently from one another.

The

(A) We say *nearly* of the same import; because *benevolence* extends to every being that has life and sense, and is of course susceptible of pain and pleasure; whereas *philanthropy* cannot comprehend more than the human race.

Philæni,
Philan-
thropy.

Philan-
thropy.

The elegant *Shaftesbury*, who had imbibed much of the spirit of Plato, endeavoured, like his master, to deduce all the duties of man, and almost all his actions, from a number of internal feelings or instincts which he supposed to be interwoven with his constitution by the immediate hand of God. This system appeared so honourable to human nature, and at the same time was so easily comprehended, that the noble lord had soon many followers, and may indeed be considered as the founder of a school which has produced philosophers whose works do honour to the age and country in which they flourished. Among these we must reckon *Bishop Butler*, *Hutchison*, *Lord Kames*, *Dr Beattie*, and perhaps *Dr Reid*.

According to the system of these writers, the whole duty of man results from an intuitive principle, to which they have given the name of the moral sense; and with this sense they conceive philanthropy to be inseparably united, or rather perhaps to make an essential part of it. (See MORAL PHILOSOPHY.) If this theory be carried to its utmost extent, as it has been by some of its patrons, it seems to follow, that peace and harmony should reign among savages; and that a man who had from his infancy grown up in solitude, would be delighted with the first sight of a fellow-creature, and run to him with eagerness as to a new source of enjoyment. This conclusion, however, is contrary to acknowledged facts. Savages are generally divided into small tribes or hordes; and though the attachment of individuals to their own tribe appears indeed to be abundantly strong, the tribes themselves are frequently at war, and entertain a constant jealousy of each other. Savages, too, are almost universally afraid of strangers; and the few solitary individuals, who have been caught in parts where they had run wild from their infancy, instead of being delighted with the appearance of fellow-men, have either fled from them with their utmost speed, or been fixed to the spot in terror and astonishment. There are no indications of that instinctive philanthropy for which some writers so strenuously plead. They have indeed induced others to deny, that in human nature there is any instinctive principles at all; and to endeavour to account for our several propensities by the influence of education producing early and deep-rooted habits.

At the head of this school stood Locke and Hartley. The former, employing himself almost wholly on the intellectual powers of man, and combating the absurd, though then generally received, belief, that there are in the human mind innate principles of speculative truth, has touched but incidentally on our principles of action. It seems, however, to be evident, that he did not consider any *one* of these principles as innate; and his opinion was adopted by Hartley, who studied the sensitive part of human nature with greater industry and success than perhaps any writer who had preceded him in that department of science. This philosopher refuses all kinds of instinct to man, even the *στροφή* of a mother to her new-born infant, and that which has been generally supposed innate—the propensity of the infant to suck the breast. It is therefore needless to say that in his theory of human nature, innate philanthropy can have no place.

The reader, however, must not suppose, that the theory of Hartley is the theory of Hobbes. Though he admits no *innate* principles of action in the human

Philan-
thropy.

mind, he is far from dreaming that the original state of man was a state of war and selfishness, or that the acquisition of philanthropic sentiments is not natural. He considers such acquisitions as even necessary and unavoidable, and founds them on the great law of association, which we have elsewhere endeavoured to explain (See METAPHYSICS, Part I. chap. v.) Hartley was a Christian, and appears to have been a man of great piety. Conceiving with Locke that men are born without any ideas, or any principles either of knowledge or of action, but that they are subject to the law of association as much as to the impressions of sense, he seems to have thought, that the important purpose for which they are sent into this world is, that they may acquire habits of piety and virtue, which, operating like instincts, will fit them for the purer society of a future state. That this theory is unfriendly to morals, no man who understands it will presume to affirm. It appears, indeed, to be more consistent with the necessity of a revelation from God than that of Shaftesbury, which has so many followers; but notwithstanding this, we cannot help thinking that the excellent author has carried his antipathy to instincts much too far (see INSTINCT), and that the truth lies in the middle between him and his opponents.

Without some instincts to influence before the dawn of reason, it is not easy to be conceived how children could be induced to that exercise which is absolutely necessary to life and health; nor does it appear with sufficient evidence that the human race are deserted by every instinct as soon as their rational powers are evolved. It seems to be a matter of fact which cannot be controverted, that women have an instinctive attachment to their new-born infants; but that these, when they become capable of distinguishing objects, are *instinctively* attached to their parents, their brothers, and sisters, is a position which, though it may be true, seems incapable of proof. That they soon appear to be so attached, is a fact which we believe no man will deny: but the attachment may be accounted for by the associating principle operating upon that desire of happiness which is necessarily formed as soon as happiness is experienced. (See PASSION). An infant becomes earlier attached to its nurse than to any other person; because, feeling wants which she supplies, the idea of enjoyment becomes soon associated in its mind with the perception of the woman. If this woman be its mother, a hasty observer immediately attributes this attachment to instinct directing the infant to love its parent; but that instinct has here no place, is evident from the well-known facts, that a child is as fond of a tender nurse, though no relation, as of the most affectionate mother; and as regardless of a mother who seldom sees it, or sees it with indifference, as of any other person. Nay, we have seen children of the sweetest dispositions as fond of the maid with whom they slept, as of a very affectionate parent by whom they had been tenderly nursed: and sure no man will say that this could be instinct; it was evidently a new association of the idea of the maid with the greatest happiness which they enjoyed after the period of their suckling was at an end.

It is much in the same way that children acquire an attachment to their brothers and sisters. Brothers and sisters being constantly together, contribute to each

Philan-
thropy.

each other's amusement: hence arises that pleasure which they have in each other's company, and the uneasiness which they feel when separated. This generates mutual love in their minds, which is strengthened by the perpetual injunctions, of their parents; for if these have any virtue themselves, they cannot fail to inculcate the duty of loving each other on their tender offspring. Benevolence, thus generated, soon extends to their daily companions; and takes a wider and a wider range as these companions are multiplied, and as children advance towards the state of manhood. New objects then present themselves to the mind. A man soon discovers, that, as he is a member of a community, his happiness as an individual depends in a great measure on the prosperity of the whole. Hence arises *patriotism*, and that pleasure which we all take in the eminence of our countrymen. But the principle of benevolence stops not here. He whose mind is enlarged by a liberal education, considers all particular countries as provinces of one great country extended over the whole globe; and all mankind, of course, as not only sharing the same nature with himself, but as being in reality his fellow-citizens and brethren. The principles of religion, if he be actuated by them, must aid these reflexions, and make him wish the happiness of all who stand in the same relation with himself to the Great Governor of the world. This is *philanthropy*; and we see how it may spring, by the great law of association, from desires which, in their original state, cannot be considered as other than selfish. It is a calm sentiment, which we believe hardly ever rises to the warmth of affection, and certainly not to the heat of passion.

Should any of our readers be disposed to controvert this opinion, or to fancy it degrading to human nature, we will not enter into controversy with them; we only beg leave to ask, whether they have ever rejoiced in the good fortune of a stranger or foreigner, or regretted his loss, with any portion of those feelings which they have frequently experienced on hearing of the prosperity or the death of a friend or a neighbour? We answer candidly for ourselves, that we feel no interest which can be called *passion* or *affection* in the fortunes of a native of China; and yet we should be sorry to think that our philanthropy is less than that of other men. A common clown, we are inclined to believe, seldom extends his affection beyond his friends and neighbours; and, though, from having often heard his country praised and knowing that he belongs to that country, he would probably be offended at the man who should prefer another to it; yet if no misfortune befall himself, or his friends and neighbours, we imagine that his grief for public calamities may be borne with patience. In his mind no such associations have been formed as compromise the good of a country, far less of all countries; and therefore his philanthropy must be confined to a very limited range. We doubt not, however, but that as opportunity offers, and as circumstances permit, such a man is ready to feed the hungry and clothe the naked of all countries; not indeed from sentiments of affection either innate or acquired, but from the obvious reflection that he is not exempted from those calamities which have befallen them, and from a still higher principle—a sense of duty to that God who has made of one blood all nations upon

earth, and commanded them to be mutually aiding Philemon,
Phileus.
to each other.

PHILEMON, a Greek comic poet, was son to Damon, and cotemporary with Menander. Any advantage he had over this poet, was owing less to his own merit than to the intrigues of his friends. Plautus has imitated his comedy *du Marchand*. He is reported to have died laughing on seeing his ass eat figs. He was then about 97 years of age. His son, Philemon the younger, was also the author of 54 comedies, of which there are still extant some considerable fragments collected by Grotius. These clearly prove that he was not a poet of the first rank. He flourished about the year 274 before our Saviour.

PHILEMON, was a rich citizen of Colossæ in Phrygia. He was converted to the Christian faith, with Appia his wife, by Epaphras the disciple of St Paul; for St Paul himself did not preach at Colossæ, Coloss. ii. 1. Perhaps we should have known nothing of St Philemon, had it not been on the account of his slave Onesimus, who having robbed him, and run away from him, came to Rome where he found St Paul, and was very serviceable to him. St Paul converted him, baptized him, and sent him back to his master Philemon; to whom he wrote a letter still extant, and which passes for a masterpiece of that kind of eloquence, natural, lively, strong, and pathetic, that was peculiar to St Paul. Philemon (1. 2.) had made a church of his house, and all his domestics, as well as himself, were of the household of faith. His charity, liberality, and compassion, were a sure refuge to all that were in distress. The Apostolical Constitutions say, that St Paul made him bishop of Colossæ; but the *Menæa* insinuate, that he went to Gaza in Palestine, of which he was the apostle and first bishop. From thence he returned to Colossæ where he suffered martyrdom with Appia his wife, in the time of Nero. They relate several particulars of his martyrdom, and say, that his body remained at Colossæ, where it performed several miracles.

PHILETAS, a Greek poet and grammarian, of the island of Cos, flourished under Philip and Alexander the Great, and was preceptor of Ptolemy Philadelphus. He was the author of some elegies, epigrams, and other works, which have not come down to us. He is celebrated in the poems of Ovid and Propertius, as one of the best poets of his age. Elian reports a very improbable story of him, namely, 'that his body was so slender and feeble, that he was obliged to have some lead in his pockets, to prevent him from being carried away by the wind.'

PHILETUS. St Paul writing to Timothy (2 Tim. ii. 16, 17, 18.) in the 65th year of Christ, and a little while before his own martyrdom, speaks thus: "But shun profane and vain babblings, for they will increase unto more ungodliness. And their word will eat as doth a canker; of whom is Hymenæus and Philetus; who concerning the truth have erred, saying, that the resurrection is past already, and overthrow the faith of some." We have nothing very certain concerning Philetus; for we make but small account of what is read in the false Abdias, in the life of St James major, even supposing this author had not put the name of Philetus; instead of Phygellus. This is the substance of what is found in Abdias. St James the son of Zebedee, passing through the synagogues of Judea
and

Philetas
||
Philip.

Philip.

and Samaria, preached everywhere the faith of Jesus Christ. Hermogenes and Philetus strenuously opposed him, affirming, that Jesus Christ was not the Messiah. Hermogenes was a notable magician, and Philetus was his disciple, who being converted, was desirous to bring his master to St James; but Hermogenes bound him up so by his magic art, that he could not come at the apostle. Philetus found means to make St James acquainted with what had happened to him; upon which St James unbound him, and Philetus came to him. Hermogenes perceiving how ineffectual his art was against the saint, became himself a convert as well as Philetus.

PHILIBEG, is a little plaid, called also *kilt*, and is a sort of short petticoat reaching nearly to the knees, worn by the Scotch Highlanders. It is a modern substitute for the lower part of the plaid, being found to be less cumbersome, especially in time of action, when the Highlanders used to tuck their breech into their girdle. Almost all of them have a great pouch of badger and other skins, with tassels dangling before, in which they keep their tobacco and money.

PHILIP, foster-brother of Antiochus Epiphanes (1 Macc. vi. 14. & 55, 2 Macc. ix. 29.), was a Phrygian by birth and very much in Antiochus's favour. This prince made him governor of Jerusalem (2 Macc. viii. 8. v. 22.) where he committed many outrages upon the Jews, to force them to forsake their religion. Seeing that Apollonius and Seron were defeated by Judas Maccabæus, he sent for new succours to Ptolemy governor of Cælo-Syria, who sent him Gorgias and Nicanor with a powerful army. Some time after, Antiochus going beyond the Euphrates, to extort money from the people, Philip went along with him; and Antiochus finding himself near his end (1 Macc. vi. 14.) made him regent of the kingdom, put his diadem into his hands, his royal cloak, and his ring, that he might render them to his son the young Antiochus Eupator. But Lysias having taken possession of the government in the name of young Eupator, who was but a child, Philip not being able to cope with him, durst not return into Syria; but he went into Egypt, carrying the body of Epiphanes along with him, there to implore assistance from Ptolemy Philometor against Lysias the usurper of the government of Syria. The year following, while Lysias was busy in the war carrying on against the Jews, Philip got into Syria, and took possession of Antioch: But Lysias returning into the country, with great diligence, retook Antioch, and put Philip to death, who was taken in the city.

PHILIP the apostle was a native of Bethsaida in Galilee. Jesus Christ having seen him, said to him, "Follow me," John i. 43. 44. &c. Philip followed him; and soon after finding Nathanael, Philip said to him, "We have found the Messiah, of whom Moses and the prophets have spoken, Jesus of Nazareth, the son of Joseph." Nathanael asked him, Can any thing good come out of Nazareth? To which Philip replied, "Come and see." Then he brought Nathanael to Jesus, and they went with him to the marriage of Cana in Galilee. St Philip was called at the very beginning of our Saviour's mission; and when Jesus Christ was about to feed the 5000 that followed him (Luke vi. 13. Mat. x. 2. John vi. 5—7.) he asked St Philip, only to prove him, whence bread might be

bought for such a multitude of people? Philip answered, that 200 penny-worth of bread would not be sufficient for every one to taste a little. Some Gentiles having a curiosity to see Jesus Christ, a little before his passion, they addressed themselves to St Philip (John xvi. 21, 22.) who mentioned it to St Andrew, and these two, to Christ. At the last supper, Philip desired our Saviour, that he would be pleased to show them the Father, being all that they desired (John xiv. 8—10.) But Jesus told them, that seeing the son they saw the Father also. This is all we find concerning Philip in the gospel.

The upper Asia fell to this apostle's lot, where he took great pains in planting the gospel, and by his preaching and miracles made many converts. In the latter part of his life, he came to Hierapolis, in Phrygia, a city very much addicted to idolatry, and particularly to the worship of a serpent of a prodigious bigness. St Philip by his prayers procured the death, or at least the disappearing, of this monster, and convinced its worshippers of the absurdity of paying divine honours to such odious creatures. But the magistrates, enraged at Philip's success, imprisoned him, and ordered him to be severely scourged, and then put to death, which some say was by crucifixion; others, by hanging him up against a pillar. St Philip is generally reckoned among the married apostles; and it is said he had three daughters, two whereof preserved their virginity, and died at Hierapolis; the third, having led a very spiritual life, died at Ephesus. He left behind him no writings. The gospel under his name was forged by the Gnostics, to countenance their bad principles and worse practices. The Christian church observes the festival of this saint, together with that of St James, on the first day of May. Euseb. lib. iii. c. 30.

PHILIP, the second of the seven deacons, was chosen by the apostles after our Saviour's resurrection. (Acts vi. 5.) This deacon, they say, was of Cæsarea in Palestine. It is certain that his daughters lived in this city (Acts xxi. 8. 9.) After the death of St Stephen, all the the Christians excepting the apostles, having left Jerusalem, and being dispersed in several places, St Philip went to preach at Samaria (*id.* viii. 1, 2, &c. where he performed several miracles, and converted many persons. He baptised them; but being only a deacon, he could not confer on them the Holy Ghost. Wherefore having made known to the apostles at Jerusalem, that Samaria had received the word of God, Peter and John came thither and the Samaritans that were converted received the Holy Ghost. St Philip was probably at Samaria when the angel of the Lord ordered him to go to the south part of the country, in the road that leads from Jerusalem to old Gaza. Philip obeyed, and there met with an Ethiopian eunuch belonging to Queen Candace, who had the care of her revenues and had been at Jerusalem to worship God there (*id.* viii. 26, 27, &c.) He was then returning from his own country, and was reading the prophet Isaiah as he went along in his chariot. Philip, hearing the eunuch reading the prophet Isaiah, said to him, Do you understand what you read? The eunuch replied, How should I understand, except somebody explain it to me? He desired Philip therefore to come and sit down by him in the chariot. The passage the eunuch was reading is this, "He was led as a sheep to the slaughter,

Philip.

and like a lamb dumb before his shearer, so he opened not his mouth." The eunuch then says to Philip, Pray, whom does the prophet speak of in this place? Is it of himself, or of some other? Then Philip began to instruct him concerning Jesus Christ. And having gone on together, they came to a fountain; when the eunuch said to Philip, Here is water, what hinders me from being baptized? Philip told him that he might be so, if he believed with all his heart. He replied, I believe that Jesus Christ is the son of God. He then ordered the chariot to stop, and they both alighted and went down into the water, while Philip baptized the eunuch. Being come out of the water, the Spirit of the Lord took away Philip, and the eunuch saw no more of him. But Philip was found again at Azotus, and he preached the gospel in all the cities he passed through, till he arrived at Cæsarea in Palestine. After this the scripture does not inform us of any particulars relating to Philip. The modern Greeks say that he went to Tralles in Asia, where he founded a church, of which he was the apostle and bishop; and where he rested in peace after performing many miracles. The Latins on the contrary, say that he died at Cæsarea, and that three of his daughters were there buried with him.

It is thought that the eunuch converted by St Philip was the first apostle of the Ethiopians; and that the Abyssines boast of having received the Christian faith from him.

PHILIP II. was the 4th son of Amyntas, king of Macedonia. He was sent to Thebes as an hostage by his father, where he learnt the art of war under Epaminondas, and studied with the greatest care the manners and the pursuits of the Greeks. He discovered, from his earliest years, that quickness of genius and greatness of courage which afterwards procured him so great a name and such powerful enemies. He was recalled to Macedonia; and at the death of his brother Perdiccas he ascended the throne as guardian and protector of the youthful years of his nephew. His ambition, however, soon discovered itself, and he made himself independent about the year 380 before Christ. The valour of a prudent general, and the policy of an experienced statesman, seemed requisite to ensure his power. The neighbouring nations, ridiculing the youth and inexperience of the new king of Macedonia, appeared in arms; but Philip soon convinced them of their error. Unable to meet them as yet in the field of battle, he suspended their fury by presents, and soon turned his arms against Amphipolis, a colony tributary to the Athenians. Amphipolis was conquered, and added to the kingdom of Macedonia, and Philip meditated no less than the destruction of a republic which had rendered itself so formidable to the rest of Greece, and had even claimed submission from the princes of Macedonia. His designs, however, were as yet immature; and before he could make Athens an object of conquest, the Thracians and the Myrians demanded his attention. He made himself master of a Thracian colony, to which he gave the name of *Philippi*, and from which he received the greatest advantages on account of the golden mines in the neighbourhood. These made it a very important capture he settled in it a number of workmen, and was the first who caused gold to be coined in his own name. He employed his wealth in procuring

Philip.

spies and partisans in all the great cities of Greece, and in making conquests without the aid of arms. It was at the siege of Methone in Thrace that Philip had the misfortune to receive a wound in his right eye from the stroke of an arrow. In the midst of his political prosperity, Philip did not neglect the honour of his family. He married Olympias the daughter of Neoptolemus, king of the Molossi; and when, some time after, he became father of Alexander, the monarch, conscious of the inestimable advantages which arise from the lessons, the example, and conversation of a learned and virtuous preceptor, wrote a letter with his own hand to the philosopher Aristotle, and begged him to retire from his usual pursuits, and to dedicate his whole time to the instruction of the young prince. Every thing seemed now to conspire to his aggrandizement; and historians have observed that Philip received in one day the intelligence of three things which could gratify the most unbounded ambition, and flatter the hopes of the most aspiring monarch: the birth of a son, an honourable crown at the olympic-games, and a victory over the barbarians of Illyricum. But all these increased rather than satiated his ambition: he declared his inimical sentiments against the power of Athens, and the independence of all Greece, by laying siege to Olynthus, a place which on account of its situation and consequence, would prove most injurious to the interests of the Athenians, and most advantages to the intrigues and military operations of every Macedonian prince. The Athenians, roused by the eloquence of Demosthenes, sent 17 vessels and 2000 men to the assistance of Olynthus; but the money of Philip prevailed over all their efforts. The greatest part of the citizens suffered themselves to be bribed by the Macedonian gold, and Olynthus surrendered to the enemy, and was instantly reduced to ruins. Philip soon after defeated the Athenians, and made a great number of them prisoners, whom he dismissed without ransom. Of this victory, the fruit of that excellent discipline which he had established in his army, the Macedonian Phalanx had the principal honour. This was a body of infantry heavily armed, consisting commonly of 16,000 men, who had each of them a shield six feet high and a pike 21 feet long. (See PHALANX). The success of his arms, and especially his generosity after victory, made his alliance and a peace, a desirable object to the people of Athens; and as both parties were inclined to this measure, it was concluded without delay. His successes were as great in every part of Greece; he was declared head of the Amphictyonic council, and was intrusted with the care of the sacred temple of Apollo at Delphi. If he was recalled to Macedonia, it was only to add fresh laurels to his crown, by victories over his enemies in Illyricum and Thessaly. By assuming the mask of a moderator and peace-maker, he gained confidence; and in attempting to protect the Peloponnesians against the encroaching power of Sparta, he rendered his cause popular; and by ridiculing the insults that were offered to his person as he passed through Corinth, he displayed to the world his moderation and philosophic virtues. In his attempts to make himself master of Eubœa, Philip was unsuccessful; and Phocion, who despised his gold as well as his meanness, obliged him to evacuate an island whose inhabitants were as insensible to the charms of money as they were unmoved

Philip.

at the horrors of war, and the bold efforts of a vigilant enemy. From Eubœa returned his arms against the Scythians; but the advantages he obtained over this indigent nation were inconsiderable, and he again made Greece an object of plunder and rapine. He advanced far in Bœotia, and a general engagement was fought at Chæronea. The fight was long and bloody, but Philip obtained the victory. His behaviour after the battle reflects great disgrace upon him as a man and as a monarch. In the hour of festivity, and during the entertainment which he had given to celebrate the trophies he had won, Philip sallied from his camp, and with the inhumanity of a brute, he insulted the bodies of the slain, and exulted over the calamities of the prisoners of war. His insolence, however, was checked, when Demades, one of the Athenian captives, reminded him of his meanness, by exclaiming, "Why do you, O king, act the part of a Therites, when you can represent with so much dignity the elevated character of an Agamemnon?" The reproof was felt; Demades received his liberty; and Philip learned how to gain popularity even among his fallen enemies, by relieving their wants and easing their distresses. At the battle of Chæronea the independence of Greece was extinguished; and Philip, unable to find new enemies in Europe, formed new enterprises, and meditated new conquests. He was nominated general of the Greeks against the Persians, and was called upon as well from inclination as duty to revenge those injuries which Greece had suffered from the invasions of Darius and of Xerxes. But he was stopped in the midst of his warlike preparations, being stabbed by Pausanias as he entered the theatre at the celebration of the nuptial of his daughter Cleopatra. This murder has given rise to many reflections upon the causes which produced it; and many who consider the recent repudiation of Olympias and the resentment of Alexander, are apt to investigate the causes of his death in the bosom of his family. The ridiculous honours which Olympias paid to her husband's murderer strengthened the suspicion; yet Alexander declared that he invaded the kingdom of Persia to revenge his father's death upon the Persian satraps and princes, by whose immediate intrigues the assassination had been committed. The character of Philip is that of a sagacious, artful, prudent, and intriguing monarch: he was brave in the field of battle, eloquent and dissimulating at home, and he possessed the wonderful art of changing his conduct according to the disposition and caprice of mankind, without ever altering his purpose, or losing sight of his ambitious aims. He possessed much perseverance, and in the execution of his plans he was always vigorous. He had that eloquence which is inspired by strong passions. The hand of an assassin prevented him from achieving the boldest and the most extensive of his undertakings; and he might have acquired as many laurels, and conquered as many nations, as his son Alexander did in the succeeding reign; and the kingdom of Persia might have been added to the Macedonian empire, perhaps with greater moderation, with more glory, and with more lasting advantages. The private character of Philip lies open to censure, and raises indignation. The admirer of his virtues is disgusted to find him among the most abandoned prostitutes, and disgracing himself by the most unnatural crimes and lascivious indulgencies

which can make even the most debauched and the most profligate to blush. He was murdered in the 47th year of his age, and the 24th of his reign, about 336 years before the Christian era. His reign is become uncommonly interesting, and his administration a matter of instruction. He is the first monarch whose life and actions are described with peculiar accuracy and historical faithfulness. Philip was the father of Alexander the Great and of Cleopatra, by Olympias; he had also by Audaca an Illyrian, Cyna, who married Amyntas the son of Perdiccas, Philip's elder brother; by Nicasipolis a Thessalian, Nicaea, who married Cassander; by Philæna a Larissæan dancer, Aridaeus, who reigned some time after Alexander's death; by Cleopatra, the niece of Attalus, Caranus and Europa, who were both murdered by Olympias; and Ptolemy the first king of Egypt, by Arsinoe, who in the first month of her pregnancy was married to Lagus. Of the many memorable actions and sayings reported by Plutarch of this prince, the following are the most remarkable. Being present at the sale of some captives in an indecent posture, one of them informed him of it; "Set this man at liberty (says Philip), I did not know that he was my friend." "Being solicited to favour a lord of his court, who was like to lose his character by a just but severe sentence, Philip refused to hearken to the solicitation, and added, "I had rather that he be disgraced than myself." A poor woman was importuning him to do her justice; and as he sent her away from day to day, under the pretence that he had no time to attend to her petition, she said to him with some warmth, "Cease then to be a king." Philip felt all the force of this reproof, and immediately gave her satisfaction. Another woman came to ask justice of him as he was going out from a great entertainment, and was condemned. "I appeal (exclaimed she)!" "And to whom do you appeal (said the king to her)?" "To Philip fasting." This answer opened the eyes of the monarch, who retracted his sentence. If he possessed any virtue, it was principally that of suffering injuries with patience. Democharus, to whom the Greeks gave the surname of *Parbesistes*, on account of his excessive petulance of tongue, was one of the deputies whom the Athenians sent to this monarch. Philip, at the conclusion of the audience, begged the ambassadors to tell him, "if he could be of any service to the Athenians;" to which Democharus gave an insolent return, which he forgave. Having learned that some Athenian ambassadors charged him, in full assembly, with atrocious calumnies: "I am under great obligations (said he to those gentlemen, for I shall henceforward be so circumpect in my words and actions, that I shall convict them of falsehood." One saying of Philip, which does him less honour than those we have before-mentioned, was, "Let us amuse children with playthings, and men with oaths." This abominable maxim, which was the soul and spring of his politics, gave rise to the observation, "That he was in full length, what Louis XI. afterwards was in miniature." It is well known that Philip had a person about him, who called out at times, "Philip remember that thou art mortal;" but whether we should place this to the account of his pride or his humility, it is difficult to say.

PHILIP V. was king of Macedonia, and son of Demetrius. His infancy, at the death of his father, was

Philip.

Ibid.

Philip. protected by Antigonus, one of his friends, who ascended the throne, and reigned for 12 years, with the title of *Independent monarch*. When Antigonus died, Philip recovered his father's throne, though only 15 years of age, and he early distinguished himself by his boldness and his ambitious views. He came to the throne in the year 220 before our Saviour, and the beginning of his reign was rendered glorious by the conquests of Aratus; a general who was as eminent for his love of justice as his skill in war. But so virtuous a character could hardly fail to be disagreeable to a prince who wanted to indulge himself in every species of dissipation and vice: and indeed his cruelty to him soon displayed his character in its true light; for to the gratification of every vice, and every extravagant propensity, he had the meanness to sacrifice this faithful and virtuous Athenian. Not satisfied with the kingdom of Macedonia, Philip aspired to become the friend of Annibal and wished to share with him the spoils which the distresses and continual loss of the Romans seemed soon to promise. But his expectations were frustrated; the Romans discovered his intrigues; and though weakened by the valour and artifice of the Carthaginian, yet they were soon enabled to meet him in the field of battle. The consul Lavinus entered, without delay his territories of Macedonia; and after he had obtained a victory over him near Apollonia, and reduced his fleet to ashes, he compelled him to sue for peace. This peaceful disposition was not permanent; and when the Romans discovered that he had assisted their formidable enemy Annibal with men and money, they appointed T. Q. Flaminius to punish his perfidy, and the violation of the treaty. The Roman consul, with his usual expedition, invaded Macedonia; and in a general engagement, which was fought near Cynocephale, the hostile army was totally defeated, and the monarch saved his life with difficulty by flying from the field of battle. Destitute of resources, without friends either at home or abroad, Philip was obliged to submit to the mercy of the conqueror, and to demand peace by his ambassadors. It was granted with difficulty: the terms were humiliating; but the poverty of Philip obliged him to accept the conditions, however disadvantageous and degrading to his dignity. In the midst of these public calamities, the peace of his family was disturbed; and Perseus, the eldest of his sons by a concubine, raised seditions against his brother Demetrius, whose condescension and humanity had gained popularity among the Macedonians, and who from his residence at Rome, as an hostage, had gained the good graces of the senate, and by the modesty and innocence of his manners had obtained forgiveness from that venerable body for the hostilities of his father. Philip listened with too much avidity to the false accusations of Perseus; and when he heard it asserted that Demetrius wished to rob him of his crown, he no longer hesitated to punish with death so unworthy and so ungrateful a son. No sooner was Demetrius sacrificed to credulity, than Philip became convinced of his cruelty and rashness: and to punish the perfidy of Perseus, he attempted to make Antigonus, another son, his successor on the Macedonian throne. But he was prevented from executing his purpose by death, in the 42d year of his reign, 178 years before the Christian c. a. The assassin of Demetrius succeeded his father, and with the same ambition, with the same rashness

and oppression renewed the war against the Romans, till his empire was destroyed, and Macedonia became a Roman province. Philip has been compared with his great ancestor of the same name; but though they possessed the same virtues, the same ambition, and were tainted with the same vices, yet the father of Alexander was more sagacious and more intriguing, and the son of Demetrius was more suspicious, more cruel, and more implacable; and, according to the pretended prophecy of one of the Sybils, Macedonia was indebted to one Philip for her rise and consequence among nations, and under another Philip she lamented the loss of her power, her empire, and her dignity.

PHILIP (M. Julius), a Roman emperor, of an obscure family in Arabia, from whence he was surnamed *Arabian*. From the lowest rank in the army he gradually rose to the highest offices; and when he was made general of the pretorian guards, he assassinated Gordian, to make himself emperor. To secure himself on the imperial throne, he left Mesopotamia a prey to the continual invasions of the Persians, and hurried to Rome, where his election was universally approved by the senate and the Roman people. Philip rendered his cause popular by his liberality and profusion; and it added much to his splendor and dignity, that the Romans during his reign commemorated the foundation of their city; a solemnity which was observed but once every 100 years, and which was celebrated with more pomp and more magnificence than under the preceding reigns. The people were entertained with games and spectacles; the theatre of Pompey was successively crowded during three days and three nights; and 2000 gladiators bled in the circus at once, for the amusement and pleasure of a gazing populace. His usurpation, however, was short. Philip was defeated by Decius, who had proclaimed himself emperor in Pannonia; and he was assassinated by his own soldiers near Verona, in the 45th year of his age, and the 5th of his reign. His son, who bore the same name, and who had shared with him the imperial dignity, was also massacred in the arms of his mother. Young Philip was then in the 12th year of his age, and the Romans lamented in him the loss of rising talents, of natural humanity, and endearing virtues.

PHILIP, a native of Acarnania, physician to Alexander the Great. When that monarch had been suddenly taken ill, after bathing in the Cydnus, Philip undertook to remove the complaint, when the rest of the physicians believed that all medical assistance would be ineffectual. But as he was preparing his medicine, Alexander received a letter from Parmenio, in which he was advised to beware of his physician Philip, as he had conspired against his life. The monarch was alarmed; and when Philip presented him the medicine, he gave him Parmenio's letter to peruse, and began to drink the potion. The serenity and composure of Philip's countenance, as he read the letter, removed every suspicion from Alexander's breast, and he pursued the directions of his physician, and in a few days recovered.

There were besides, a vast number of persons of this name in antiquity, and many of them were very eminent.

PHILIP I. king of France, succeeded his father Henry

Philip.

Ibid.

Ibid.

Philip. Henry I. in 1060, when but eight years of age, under the regency and guardianship of Baudouin V. count of Flanders, who discharged his trust with zeal and fidelity. He defeated the Gascons who were inclined to revolt, and died, leaving his pupil 15 years of age. This young prince made war in Flanders against Robert, Baudouin's younger son, who had invaded Flanders, which belonged to the children of his elder brother. Philip marched against him with a numerous army, which was cut to pieces near Mount Cassel. Peace was the consequence of the victory, and the conqueror quietly enjoyed his usurpation. Philip, after the fatigues of the war, by way of relaxation gave himself up entirely to pleasure and dissipation. Tired of his wife Bertha, and fond of Bertrade, spouse of Foulques count of Anjou, he carried her off from her husband. Having in 1093, legally annulled his own marriage, under the pretext of barrenness, and Bertrade's marriage with the count of Anjou having been set aside under the same pretext, Philip and she were afterwards solemnly married by the bishop of Beauvais. This union was declared void by Pope Urban II. a Frenchman by birth, who pronounced the sentence in the king's own dominions, to which he had come for an asylum. Philip, fearing that the anathemas of the Roman pontiff might be the means of exciting his subjects to rebellion, sent deputies to the pope, who obtained a delay, during which time he was permitted to use the crown. To know what is meant by this permission, it is necessary to recollect, that at that period kings appeared on public solemnities in royal habit, with the crown on their heads, which they received from the hand of a bishop. This delay was not of long duration. Philip was excommunicated anew in a council held at Patisiers in 1100; but in the year 1104, Lambert bishop of Arras, legate of Pope Paschal II. at last brought him his absolution to Paris, after having made him promise never to see Bertrade more; a promise which he did not keep. It would appear that the pope afterwards approved their marriage; for Suger informs us, that their sons were declared capable of succeeding to the crown. Philip died at Melun the 29th of July 1108, aged 57 years after having witnessed the first crusade, in which he declined taking any part. His reign, which comprehends a period of 48 years, was the longest of any of his predecessors, excepting that of Clotarius, and of all who came after him except those of Louis XIV. and Louis XV. It was distinguished by several great events: but Philip, though brave in battle, and wise in counsels, was no very excellent character. He appeared so much the more contemptible to his subjects, as that age abounded with heroes. Philip is not the first of the French monarchs (as is commonly reported), who, in order to give the greater authority to his charters, caused them to be subscribed by the officers of the crown; for Henry I. had sometimes done the same before him.

PHILIP II. surnamed *Augustus*, the conqueror and *given of God*, son of Louis VII. (called the *younger*). King of France, and of Alix, his third wife, daughter of Thibault, count of Champagne, was born the 22d of August 1165. He came to the crown, after his father's death in 1180, at the age of 15 years. His youth was not spent like that of the generality of other princes, for, by avoiding the rock of plea-

sure on which so many are apt to split, his courage thereby became the more lively and intrepid. The king of England seemed willing to take advantage of his minority, and to seize upon a part of his dominions. But Philip marched against him, and compelled him, sword and hand, to confirm the ancient treaties between the two kingdoms. As soon as the war was ended, he made his people enjoy the blessings of peace. He gave a check to the oppressions of the great lords, banished the comedians, punished blasphemies, caused the streets and public places of Paris to be paved, and annexed to that capital a part of the adjacent villages. It was inclosed by walls with towers; and the inhabitants of other cities were equally proud to fortify and embellish theirs. The Jews having for a long time practised the most shameful frauds in France, Philip expelled them from his kingdom, and declared his subjects quit with them; an action unjust, contrary to the laws of nature, and consequently to religion. The tranquillity of France was somewhat disturbed by a difference with the count of Flanders, which was however happily terminated in 1184. Some time after he declared war against Henry II. king of England, and took from him the towns of Moudun, Tours, Mans and other places. The epidemical madness of the crusades then agitated all Europe; and Philip, as well as other princes, caught the infection. He embarked in the year 1190, with Richard I. king of England, for the relief of the Christians in Palestine who were oppressed by Saladin. Those two monarchs sat down before Acre, which is the ancient Ptolemais; as did almost all the Christians of the east, while Saladin was engaged in a civil war on the banks of the Euphrates. When the two European monarchs had joined their forces to those of the Asiatic Christians, they counted above 300,000 fighting men. Acre surrendered the 13th of July 1191; but the unhappy disagreement which took place between Philip and Richard, rivals of glory and of interest, did more mischief than could be compensated by the successful exertions of those 300,000 men. Philip, tired of these divisions and displeased with the behaviour of Richard his vassal, returned to his own country, which perhaps he should never have left, or at least have seen again with more glory. Besides, he was attacked (say historians) with a languishing disorder, the effects of which were attributed to poison; but which might have been occasioned merely by the scorching heat of a climate so different from that of France. He lost his hair, his beard, and his nails; nay, his very flesh came off. The physicians urged him to return home: and he soon determined to follow their advice. The year after, he obliged Baudouin VIII. count of Flanders to leave him the county of Artois. He next turned his arms against Richard king of England, from whom he took Evreux and Vexin; though he had promised upon the holy gospels never to take any advantage of his rival during his absence; so that the consequences of this war were very unfortunate. The French monarch repulsed from Rouen with loss, made a truce for six months; during which time he married Ingelburge, princess of Denmark, whose beauty could only be equalled by her virtue. The divorcing of this lady, whom he quitted in order to marry Agnes daughter of the duke of Merania, embroiled him with the court of

Philip

Philip. Rome. The pope issued a sentence of excommunication against him; but it was taken off upon his promising to take back his former wife. John Sans-terre, succeeded to the crown of England in 1199, to the prejudice of his nephew Arthur, to whom of right it belonged. The nephew, supported by Philip, took arms against the uncle, but was defeated in Poitou, where he was taken prisoner, and afterwards murdered. The murderer being summoned before the court of the peers of France, not having appeared, was declared guilty of his nephew's death, and condemned to lose his life in 1203. His lands, situated in France, were forfeited to the crown. Philip soon set about gathering the fruit of his vassal's crime. He seized upon Normandy, then carried his victorious arms into Maine, Anjou, Touraine, Poitou, and brought those provinces, as they anciently were, under the immediate authority of his crown. The English had no other part left them in France but the province of Guienne. To crown his good fortune, John his enemy was embroiled with the court of Rome; which had lately excommunicated him. This ecclesiastical thunder was very favourable for Philip. Innocent II. put into his hands, and transferred to him, a perpetual right to the kingdom of England. The king of France, when formerly excommunicated by the pope, had declared his censures void and abusive; he thought very differently, however, when he found himself the executor of a bull investing him with the English crown. To give the greater force to the sentence pronounced by his holiness, he employed a whole year in building 1700 ships, and in preparing the finest army that was ever seen in France. Europe was in expectation of a decisive battle between the two kings, when the pope laughed at both, and artfully took to himself what he had bestowed upon Philip. A legate of the holy see persuaded John Sans-terre to give his crown to the court of Rome, which received it with enthusiasm. Then Philip was expressly forbid by the pope to make any attempt upon England, now become a fee of the Roman church, or against John who was under her protection. Meanwhile, the great preparations which Philip had made alarmed all Europe; Germany, England, and the Low-Countries were united against him in the same manner as we have seen them united against Louis XIV. Ferrand, count of Flanders, joined the emperor Otho IV. He was Philip's vassal; which was the strongest reason for declaring against him. The French king was nowise disconcerted; his fortune and his courage dissipated all his enemies. His valour was particularly conspicuous at the battle of Bouvines, which was fought on the 27th of July 1214, and lasted from noon till night. Before the engagement, he knew well that some of his nobles followed him with reluctance. He assembled them together; and placing himself in the midst of them, he took a large golden cup, which he filled with wine, and into which he put several slices of bread. He cat one of them himself, and offering the cup to the rest, he said, "My companions, let those who would live and die with me follow my example." The cup was emptied in a moment, and those who were the least attached to him fought with all the bravery that could be expected from his warmest friends. It is also reported that after showing the army the crown that was worn by

sovereigns upon these occasions, he said, "If any one thought himself more worthy than he was to wear it, he had only to explain himself; that he should be content it were the prize of that man who should display the greatest valour in battle." The enemy had an army of 150,000 fighting men; that of Philip was not half so numerous; but it was composed of the flower of his nobility. The king run great hazard of his life; for he was thrown down under the horses feet, and wounded in the neck. It is said 30,000 Germans were killed; but the number is probably much exaggerated. The counts of Flanders and Boulogne were led to Paris with irons upon their feet and hands; a barbarous custom which prevailed at that time. The French king made no conquest on the side of Germany after this ever memorable action; but it gained him an additional power over his vassals. Philip, conqueror of Germany, and possessor of almost all the English dominions in France, was invited to the crown of England by the subjects of King John, who were grown weary of his tyranny. The king of France, upon this occasion, conducted himself like an able politician. He persuaded the English to ask his son Louis for their king; but as he wished at the same time to manage the pope, and not lose the crown of England, he chose to assist the prince his son, without appearing to aid himself. Louis made a descent upon England, was crowned at London, and excommunicated at Rome in 1216; but that excommunication made no change upon John's situation, who died of grief. His death extinguished the resentment of the English, who having declared themselves for his son Henry III. forced Louis to leave England. Philip-Augustus died a little time after, at Mantes, the 14th of July 1223, aged 59, after a reign of 43 years. Of all the kings of the 3d race, he made the greatest accession to the crown-lands, and transmitted the greatest power to his successors. He reunited to his dominions Normandy, Anjou, Maine, Touraine, Poitou, &c. After having subdued John Sans-terre, he humbled the great lords, and by the overthrow of foreign and domestic enemies, took away the counterpoise which balanced his authority in the kingdom. He was more than a conqueror; he was a great king and an excellent politician; fond of splendor on public occasions, but frugal in private life; exact in the administration of justice; skilful in employing alternately flattery and threatenings, rewards and punishments; he was zealous in the defence of religion, and always disposed to defend the church; but he knew well how to procure from her succours for supplying the exigencies of the state. The lords of Coucy, Rhetel, Rossey, and several others, seized upon the property of the clergy. A great many of the prelates applied for protection to the king, who promised them his good offices with the deprecators. But, notwithstanding his recommendations, the pillages continued. The bishops redoubled their complaints, and intreated Philip to march against their enemies. "With all my heart (said he): but in order to fight them, it is necessary to have troops, and troops cannot be raised without money." The clergy understood his meaning; they furnished subsidies, and the pillages ceased. The enterprises of Philip Augustus were almost always successful: because he formed his projects with deliberation, and executed them without delay. He began by

Philip.

Philip. rendering the French happy, and in the end rendered them formidable; though he was more inclined to anger than to gentleness, to punish than to pardon, he was regretted by his subjects as a powerful genius, and as the father of his country. It was in his reign that the marshal of France was seen, for the first time, at the head of the army. It was then also, that families began to have fixed and hereditary surnames; the lords took them from the lands which they possessed; men of letters from the place of their birth; the converted Jews and rich merchants from that of their residence. Two very cruel evils, *viz.* leprosy and usury, were prevalent at that time; the one infected the body; the other proved the ruin of the fortunes of families. The number of lepers was so great, that the smallest villages were obliged to have an hospital for the cure of that distemper. It is remarkable, that when Philip was on the point of engaging Richard, the English who were lying in ambush near the Loire, run away with his equipages, in which he caused to be carried all the deeds or writings respecting the rights of the crown; a custom which is used at this day by the grand seignior. Philip caused copies of his charters to be collected wherever they could be found; but after all his endeavours some of them were never recovered. The surname of *Augustus* was given to Philip by his contemporaries. Mezerai is mistaken, when he asserts that Paulus Emilius was the first who rendered the name of *conqueror* by that of *Augustus*; a learned critic has proved the contrary by undoubted authorities.

PHILIP of Valois, first king of France of the collateral branch of the Valois, was son to Charles count of Valois, brother of Philip the Fair. He mounted the throne in 1328, on the death of his cousin Charles the Fair, after having held for some time the regency of the kingdom. France was much divided in the beginning of his reign, by disputes about the succession to the crown. Edward III. king of England laid claim to it as grandson of Philip the Fair, by his mother; but Philip of Valois took possession of it as first prince of the blood. The people gave him upon his accession to the throne, the title of *fortunate*; to which might have been added, for some time, those of *victorious* and *just*. He marched to the relief of his vassal the count of Flanders, whose subjects, on account of bad usage, had taken up arms against him. He engaged the rebels at Cassel, performed prodigies of valour, and gained a signal victory, the 24th of August 1328. Having made all quiet, he went home, after saying to the count of Flanders, "Be more prudent and more humane, and you will have fewer disloyal subjects." The victorious Philip devoted the time of peace to the internal regulations of his kingdom. The financiers were called to an account, and some of them condemned to death; among others Peter Reni, general of the finances, who left behind him near 20 millions. He afterwards enacted the law respecting freeholds, imposing a tax upon churches, and commoners who had acquired the lands of the nobility. Then, also, began to be introduced the form of *appeal comme d'abus*, the principles of which are more ancient than the name. The year 1329 was distinguished by a solemn homage paid to Philip, by Edward king of England, for the duchy of Guienne, upon his knees, and with his head uncovered. The interior peace of the kingdom was disturbed by disputes about the distinction of

the church and state. An assembly was summoned for hearing the two parties, in the presence of the king; and in this assembly Peter de Cuguières, his majesty's advocate, defended the secular jurisdiction with great ability as a man well-informed, and an enlightened philosopher. Bertrand bishop of Autun, and Roger archbishop of Sens, pleaded the cause of the clergy with less ingenuity and judgment. This did not, however prevent the king from showing them favours, though the controversy itself laid the foundation of all the disputes which were afterwards agitated about the authority of the two powers; disputes which contributed not a little to confine the ecclesiastical jurisdiction within narrower limits. While Philip was employing himself in some useful regulations, he was unhappily interrupted by Edward III. declaring war against France. This prince immediately recovered those parts of Guienne of which Philip was in possession. The Flemish having again revolted from France in spite of oaths and treaties, joined the standard of Edward; and required that he would assume the title of *king of France*, in consequence of his pretensions to the crown; because then, agreeably to the letter of their treaty, they only followed the king of France. From this period is dated the union of the flower-de-luce and leopards in the arms of England. Edward, in order to justify the change of his arms, caused the following manifesto to be published in the verse of the times.

*Rex sum regnorum, bina ratione, duorum :
Anglorum in regno sum rex ego jure paterno :
Matris jure quiaem Francorum nuncupor idem ;
Hinc est armorum variatio facta morum.*

In the way of a parody to these lines, Philip made the following reply :

*Prædo regnorum qui diceris esse duorum,
Francorum regno privaberis, atque paterno.
Succedunt mares huic regno, non mulieres :
Hinc est armorum variatio sulta tuorum.*

In the mean time Philip put himself in a posture of defence. His arms were at first attended with some success; but those advantages were far from compensating the loss of the battle of Ecluse, in which the French fleet, consisting of 120 large ships, and manned by 40,000 seamen, was beat by that of England in the year 1340. This defeat is to be attributed, in part, to the little attention which had been paid to the navy of France, notwithstanding her favourable situation, by being washed by two seas. She was obliged to make use of foreign ships, which obeyed but slowly, and even with some reluctance. This war, which had been alternately discontinued and renewed begun again with more heat than ever in 1345. The two armies having come to an engagement the 26th of August 1346, near Crecy, a village in the county of Ponthieu, the English there gained a signal victory. Edward had only 20,000 men, while Philip had nearly twice that number; but the army of the former was inured to war, and that of the latter was ill disciplined and overcome with fatiguing marches. France lost from 25,000 to 30,000 men; of which numbers were John king of Bohemia (who though blind, fought gallantly), and about 1500 gentlemen, the flower of the French nobility. The loss of Calais, and several other

Philip.

Philip.

other places, was the sad fruit of this defeat. Some time before Edward had challenged Philip of Valois to a single combat; which he refused, not on the score of cowardice, but from the idea that it was improper for a sovereign prince to accept a challenge from a king who was his vassal. At length, in 1347, a truce for six months was concluded between France and England, and afterwards prolonged at different times. Philip died a short time after, the 23d of August 1350, aged 57 years, and far from bearing on his monument the title of *Fortunate*. He had, however, reunited Dauphiny to France. Humbert, the last prince of that country, having lost all his children, and wearied with the wars which he had held out against Savoy, turned a Dominican, and gave his province to Philip, in 1349, on condition that the eldest son of the kings of France should bear the title of Dauphin. Philip likewise added to his domain Roussillon and a part of Cerdagne, by lending some money to the king of Majorca, who gave him those provinces as a security; provinces which Charles VIII. afterwards restored without any reimbursement. It is surprising that in so unfortunate a reign he should have been able to purchase those provinces after having paid a great deal for Dauphiny; but the duty on salt, the rise on the other taxes, and especially the frauds committed in the coinage of money, are supposed to have enabled him to make those acquisitions. The fictitious and ideal value of the coin was not only raised, but a great deal of bad money was issued from the mint. The officers of the mint were sworn upon the Gospels to keep the secret: but how could Philip flatter himself that so gross a fraud would not be discovered?

PHILIP II. son of Charles V. and of Isabella of Portugal, who was born at Valladolid on the 21st of May 1527, became king of Naples and Sicily by his father's abdication in 1554. He ascended the throne of Spain on the 17th of January 1556 by the same means. Charles had made a truce with the French, but his son broke it; and having formed an alliance with England, poured into Picardy an army of 40,000 men. The French were cut to pieces at the battle of St Quintin, which was fought on the 20th of August 1557. That town was taken by assault, and the day on which the breach was mounted Philip appeared armed cap-a-pee in order to animate the soldiers. It was the first and last time that he was observed to wear this military dress. It is well known, indeed, that his terror was so great during the action that he made two vows; one, that he should never again be present in a battle; and the other, to build a magnificent monastery dedicated to St Lawrence, to whom he attributed the success of his arms, which he executed at Escorial, a village about seven leagues from Madrid. After the engagement, his general the Duke of Savoy, wanted to kiss his hand; but Philip prevented him saying, "It is rather my duty to kiss your's, who have the merit of so glorious a victory;" and immediately presented him with the colours taken during the action. The taking of Catelet, Ham, and Noyen, were the only advantages which were derived from a battle which might have proved the ruin of France. When Charles V. was informed of this victory, it is said he asked the person who brought him the intelligence, "if his son was at Paris?" and being answered in the negative, he went away without uttering a

single word. The Duke of Guise having had time to assemble an army, repaired the disgrace of his country by the taking of Calais and Thionville. While he was animating the French, Philip gained a pretty considerable battle against Marshal de Thermes near Gravelines. His army was, on this occasion, commanded by count Egmont, whom he afterwards caused to be beheaded. The conqueror made no better use of the victory of Gravelines than he had done of that of St Quintin; but he reaped considerable advantage from the glorious peace of Chateau-Cambresis, the master-piece of his politics. By that treaty, concluded the 13th of April 1559, he gained possession of the strong places of Thionville, Mariembourg, Montmedin, Hesdin, and the county of Charollois. This war, so terrible, and attended with so much cruelty, was terminated like many others, by a marriage. Philip took for his third wife Elizabeth, daughter of Henry II. who had been promised to Don Carlos.

After these glorious achievements, Philip returned in triumph to Spain without having drawn a sword. His first care, upon his arrival at Valladolid, was to demand of the grand inquisitor the spectacle of an *auto-da-fé*. This was immediately granted him; 40 wretches, some of whom were priests or monks, were strangled and burnt, and one of them was burnt alive. Don Carlos de Seza, one of those unfortunate victims, ventured to draw near to the king, and said to him, "How, Sir, can you suffer so many wretches to be committed to the flames? Can you be witness of such barbarity without weeping?" To this Philip coolly replied, "If my own son were suspected of heresy, I would myself give him up to the severity of the inquisition. Such is the horror which I feel when I think of you and your companions, that if an executioner were wanting, I would supply his place myself." On other occasions he conducted himself agreeably to the spirit which had dictated this answer. In a valley of Piedmont, bordering on the country of the Milanese, there were some heretics; and the governor of Milan had orders to put them all to death by the gibbet. The new opinions having found their way into some of the districts of Calabria, he gave orders that the innovators should be put to the sword, with the reservation of 60 of them, of whom 30 were afterwards strangled, and the rest committed to the flames.

This spirit of cruelty, and shameful abuse of his power, had the effect to weaken that power itself. The Flemish, no longer able to bear so hard a yoke, revolted. The revolution began with the fine and large provinces of the continent; but the maritime provinces only obtained their liberty. In 1579 they formed themselves into a republic, under the title of the United Provinces. Philip sent the Duke of Alva to reduce them: but the cruelty of that general only served to exasperate the spirit of the rebels. Never did either party fight with more courage, or with more fury. The Spaniards, at the siege of Haerlem, having thrown into the town the head of a Dutch officer who had been killed in a skirmish, the inhabitants threw to them the heads of eleven Spaniards, with this inscription: "Ten heads for the payment of the tenth penny, and the eleventh for interest." Haerlem having surrendered at discretion, the conquerors caused all the magistrates, all the pastors, and above 1500 citizens, to be hanged.

Philip.

Philip.

The Duke of Alva, being at length recalled, the grand commander of the Requesnes was sent in his place, and after his death Don John of Austria; but neither of those generals could restore tranquility in the Low Countries. To this son of Charles V. succeeded a grandson no less illustrious, namely, Alexander Farnese duke of Parma, the greatest man of his time; but he could neither prevent the independence of the United provinces, nor the progress of that republic which arose under his own eye. It was then that Philip, always at his ease in Spain, instead of coming to reduce the rebels in Flanders, proscribed the Prince of Orange, and set 25,000 crowns upon his head. William, superior to Philip, disdained to make use of that kind of vengeance, and trusted to his sword for his preservation.

In the mean time the king of Spain succeeded to the crown of Portugal, to which he had a right by his mother Isabella. This kingdom was subjected to him by the Duke of Alva, in the space of three weeks, in the year 1580. Antony, prior of Crato, being proclaimed king by the populace of Lisbon, had the resolution to come to an engagement; but he was vanquished, pursued, and obliged to fly for his life.

A cowardly assassin, Balthazar Gerard, by a pistol-shot killed the Prince of Orange, and thereby delivered Philip from his most implacable enemy. Philip was charged with this crime, it is believed without reason; though, when the news was communicated to him, he was imprudent enough to exclaim, "If this blow had been given two years ago, the Catholic religion and I would have gained a great deal by it."

This murder had not the effect to restore to Philip the Seven United Provinces. That republic, already powerful by sea, assisted England against him. Philip having resolved to distress Elizabeth, fitted out, in 1588, a fleet called the *Invincible*. It consisted of 150 large ships, on which were counted 2650 pieces of cannon, 8000 seamen, 20,000 soldiers, and all the flower of the Spanish nobility. This fleet, commanded by the Duke of Medina Sidonia, sailed from Lisbon when the season was too far advanced: and being overtaken by a violent storm, a great part of it was dispersed. Twelve ships, driven upon the Coast of England, were captured by the English fleet, which consisted of 100 ships; 50 were wrecked on the coasts of France, Scotland, Ireland, Holland, and Denmark. Such was the success of the *Invincible*. See *ARMADA*.

This enterprise, which cost Spain 40 millions of ducats, 20,000 men, and 100 ships, was productive only of disgrace. Philip supported this misfortune with an heroic resolution. When one of his courtiers told him with an air of consternation, what had happened, he coolly replied, "I sent to fight the English, and not the winds. God's will be done." The day after Philip ordered the bishops to return thanks to God for having preserved some remains of his fleet; and he wrote thus to the pope: "Holy father, as long as I remain master of the fountain-head, I shall not much regard the loss of a rivulet. I will thank the Supreme Disposer of empires, who has given me the power of easily repairing a disaster which my enemies must attribute solely to the elements which have fought for them."

At the same time that Philip attacked England, he was encouraging in France the Holy League: the ob-

ject of which was to overturn the throne and divide the state. The leaguers conferred upon him the title of *Protector* of their association; which he eagerly accepted, from a persuasion that their exertions would soon conduct him or one of his family, to the throne of France. He thought himself so sure of his prey, that when speaking of the principal cities in France, he used to say, "My fine city of Paris, my fine city of Orleans," in the same manner as he would have spoken of Madrid and Seville. What was the result of all these intrigues? Henry IV. embraced the Catholic religion, and by his abjuration of Protestantism made his rival lose France in a quarter of an hour.

Philip, at length, worn out by the debaucheries of his youth, and by the toils of government, drew near his last hour. A slow fever, the most painful gout, and a complication of other disorders, could not disengage him from business, nor draw from him the least complaint. "What!" said he to the physicians who hesitated about letting blood of him; "What! are you afraid of drawing a few drops of blood from the veins of a king who has made whole rivers of it flow from heretics?" At last, exhausted by a complication of distempers, which he bore with an heroic patience, and being eaten up of lice, he expired the 13th of September 1598, aged 72 years, after a reign of 43 years and eight months. During the last 50 days of his illness he showed a great sense of religion, and had his eyes almost always fixed towards heaven.

No character was ever drawn by different historians in more opposite colours than that of Philip; and yet, considering the length and activity of his reign, there is none which it should seem would be more easy to ascertain. From the facts recorded in history, we cannot doubt that he possessed, in an eminent degree, penetration, vigilance, and a capacity for government. His eyes were continually open upon every part of his extensive dominions. He entered into every branch of administration; watched over the conduct of his ministers with unwearied attention; and in his choice both of them and of his generals discovered a considerable share of sagacity. He had at all times a composed and settled countenance, and never appeared to be either elated or depressed. His temper was the most imperious, and his looks and demeanor were haughty and severe; yet among his Spanish subjects he was of easy access; listened patiently to their representations and complaints; and where his ambition and bigotry did not interfere, was generally willing to redress their grievances. When we have said thus much in his praise, we have said all that truth requires or truth permits. It is indeed impossible to suppose that he was sincere in his zeal for religion. But as his religion was of the most corrupt kind, it served to increase the natural depravity of his disposition: and not only allowed, but even prompted, him to commit the most odious and shocking crimes. Although a prince in the bigotted age of Philip might be persuaded that the interest of religion would be advanced by falsehood and persecution; yet it might be expected, that, in a virtuous prince, the sentiments of honour and humanity would on some occasions triumph over the dictates of superstition: but of this triumph there occurs not a single instance in the reign of Philip; who without hesitation violated his most sacred obli-

Philip.

Watson's Philip II.

Philip. gations as often as religion afforded him a pretence, and under that pretence exercised for many years the most unrelenting cruelty without reluctance or remorse. His ambition, which was exorbitant; his resentment, which was implacable; his arbitrary temper, which would submit to no controul—concurrent with his bigotted zeal for the Catholic religion, and carried the sanguinary spirit, which that religion was calculated to inspire, to a greater height in Philip than it ever attained in any other prince of that or of any former or succeeding age.

Though of a small size, he had an agreeable person. His countenance was grave, his air tranquil, and one could not discover from his looks either joy in prosperity or chagrin in adversity. The wars against Holland, France, and England, cost Philip 564 millions of ducats: But America furnished him with more than the half of that sum. His revenues, after the junction of Portugal, are said to have amounted to 25 millions of ducats, of which he only laid out 100,000 for the support of his own household. Philip was very jealous of outward respect; he was unwilling that any should speak to him but upon their knees. The duke of Alva having one day entered this prince's cabinet without being introduced, he received the following harsh salutation, accompanied with a stormy countenance: "An impudence like this of yours would deserve the hatchet." If he thought only how to make himself be feared, he succeeded in doing so; for few princes have been more dreaded, more abhorred, or have caused more blood to flow, than Philip II. of Spain. He had successively, if not all at once, war to maintain against Turkey, France, England, Holland, and almost all the Protestants of the empire, without having a single ally, not even the branch of his own house in Germany. Notwithstanding so many millions employed against the enemies of Spain, Philip found in his œconomy and his resources wherewith to build 30 citadels, 64 fortified places, 9 sea-ports, 25 arsenals, and as many palaces, without including the œcurial. His debts amounted to 140 millions of ducats, of which, after having paid seven millions of interest, the greatest part was due to the Genoese. Moreover, he had sold or alienated a capital stock of 100 millions of ducats in Italy. He made a law, fixing the majority of the kings of Spain at 14 years of age. He affected to be more than commonly devout; he eat often at the refectory with the monks; he never entered their churches without kissing all the relics; he caused knead his bread with the water of a fountain which was thought to possess a miraculous virtue; he boasted of never having danced, and of never wearing breeches after the Grecian fashion. Grave and solemn in all his actions, he drove from his presence a woman who had smiled while he was blowing his nose. One great event of his domestic life is the death of his son Don Carlos. The manner of this prince's death is not certainly known. His body, which lies in the monument of the œcurial, is there separated from his head: but it is pretended that the head is separated only because the leaden coffin which contains the body is too small. The particulars of his crime are as little known as the manner in which it was committed. There is no evidence, nor is there any probability, that Philip would have caused him to be con-

demned by the inquisition. All that we know of the matter is, that in 1568 his father, having discovered that he had some correspondence with the Hollanders his enemies, arrested him himself in his own room. He wrote at the same time to Pope Pius V. in order to give him an account of his son's imprisonment; and in his letter to this pontiff, the 20th of January 1568, he says, "that from his earliest years the strength of a wicked nature has stifled in Don Carlos every paternal instruction." It was Philip II. who caused to be printed at Anvers, between 1569 and 1572, in 8 vols folio, the fine Polyglot Bible, which bears his name; and it was he who subjected the islands afterwards called the *Philippines*. He married successively, 1st, Mary daughter of John III. king of Portugal; 2dly, Mary daughter of Henry VIII. and queen of England; 3dly, Elizabeth of France, daughter of Henry II.; 4thly, Anne, daughter of the Emperor Maximilian II. Don Carlos was the son of his first wife, and Philip III. of the last.

PHILIPPI (anc. geog.), a town of Macedonia, in the territory of the Edones, on the confines of Thrace (Pliny, Ptolemy), situated on the side of a steep eminence; anciently called *Datum* and *Drenides* (Appian), though Strabo seems to distinguish them. This town was famous on several accounts; not only as taking its name from the celebrated Philip of Macedon, father to Alexander the Great, who considered it as a fit place for carrying on the war against the Thracians; but also on account of two battles fought in its neighbourhood between Augustus and the republican party. In the first of these battles, Brutus and Cassius had the command of the republican army; while Octavianus, afterwards Augustus, and Mark Antony, had the command of their adversaries. The army of Brutus and Cassius consisted of 19 legions and 20,000 horse; the imperial forces of an equal number of legions, but more complete, and 13,000 horse; so that the numbers on both sides were pretty equal. The troops of Brutus were very richly dressed, most of them having their armour adorned with gold and silver; for Brutus, though very frugal in other respects, was thus extravagant with respect to his men, thinking that the riches that they had about them would make them exert themselves the more, to prevent these from falling into the enemy's hands. Both the republican generals appear to have been inferior in skill to Mark Antony; for as to Octavianus, he is allowed never to have conquered but by the valour of others. A little before the first engagement, Octavianus, who had been indisposed, was carried out of the camp, at the persuasion of Artorius his physician, who had dreamed that he saw a vision directing him to be removed. Brutus's men, who opposed the wing commanded by Octavianus, charged without orders, which caused great confusion. However, they were successful; for part of them, taking a compass about, fell upon the enemy's rear: after which they took and plundered the camp, making a great slaughter of such as were in it, and among the rest putting 2000 Lacedæmonians to the sword who were newly come to the assistance of Octavianus. The emperor himself was fought for, but in vain, having been conveyed away for the reason above-mentioned; and as the soldiers pierced the litter in which he was usually carried, it was thence reported that

Philippi.

Philippi,
Philippics.

that he had been killed. This threw that whole part of the army into such consternation, that when Brutus attacked them in front, they were most completely routed: three whole legions being cut in pieces, and a prodigious slaughter made among the fugitives. But by the imprudence of the general in pursuing too far, the wing of the republican army commanded by Cassius was left naked and separated from the rest of the army; on which they were attacked at once in front and in flank, and thus they were defeated and their camp taken, while Brutus imagined that he had gained a complete victory. Cassius himself retired to an eminence at a small distance from Philippi; whence he sent one of his greatest intimates to procure intelligence concerning the fate of Brutus. That general was on his way, and already in view, when the messenger set out. He soon met his friends; but they surrounding him to inquire the news, Cassius who beheld what passed, imagined that he was taken prisoner by the enemy, retired to his tent, and in despair caused one of his freedmen cut off his head. Thus far at least is certain, that he went into the tent with that freedman, and that his head was found separated from his body when Brutus entered. However, the freedman was never afterwards seen.

The second engagement was pretty similar to the first. Brutus again opposed Octavianus, and met with the same success; but in the mean time Antony, to whom he ought undoubtedly to have opposed himself, having to do only with the lieutenants of Cassius gained a complete victory over them. What was worst, the fugitives, instead of leaving the field of battle altogether, fled for protection to Brutus's army; where, crowding in among the ranks, they carried despair and confusion wherever they went, so that a total defeat ensued, and the republican army was almost entirely cut in pieces. After the battle, Brutus put an end to his own life, as is related more fully under the article *ROMÉ*.

The city of Philippi is likewise remarkable on account of an epistle written by St Paul to the church in that place. It was a Roman colony (Luke, Pliny, Coin, Inscription). It is also remarkable for being the birth place of Akratius, the Peripatetic philosopher, and disciple of Aristotle.—The town is still in being, and is an archbishop's see; but greatly decayed and badly peopled. However, there is an old amphitheatre, and several other monuments of its ancient grandeur. E. Long. 44. 55. N. Lat. 41. 0.

PHILIPPICS, *φιλιππικαὶ λόγοι*, in literature, is a name which is given to the orations of Demosthenes against Philip king of Macedon. The Philippics are reckoned the master-pieces of that great orator: Longinus quotes many instances of the sublime from them, and points out a thousand latent beauties. Indeed that pathetic in which Demosthenes excelled, the frequent interrogations and apostrophes wherewith he attacked the indolence of the Athenians, where could they be better employed? Whatever delicacy there be in the oration against Leptines, the Philippics have the advantage over it, were it only on account of the subject, which gives Demosthenes so fair a field to display his chief talent, we mean, with Longinus, that of moving and astonishing.

Dionysius Halicarnassensis ranks the oration on the

Halonesse among the Philipics, and places it the eighth in order: but though his authority be great, yet that force and majesty wherein Cicero characterises the Philipics of Demosthenes, seem to exclude the oration on the Halonesse out of the number; and authorise the almost universal opinion of the learned, who reject it as spurious. Libanius, Photius, and others, but above all the languidness of the style, and the lowness of the expressions, which reign throughout the whole, rather it on Hegetippus.

PHILIPPIC is likewise applied to the fourteen orations of Cicero against Mark Antony. Cicero himself gave them this title in his epistles to Brutus: and posterity have found it so just, that it has been continued to our times. Juvenal, Sat. x. calls the second the *divine Philippic*, and witnesses it to be of great fame, *conspicua divina Philippica fame*. That orator's intitling his last and most valued orations after the Philipics of Demosthenes shows the high opinion he had of them. Cicero's Philipics cost him his life; Mark Antony had been so irritated with them, that when he arrived at the triumvirate, he procured Cicero's murder, cut off his head, and stuck it up in the very place whence the orator had delivered the Philipics.

PHILIPPINE ISLANDS, are certain islands of Asia, which lie between 114 and 126 degrees of east longitude, and between 6 and 20 degrees of north latitude; about 300 miles south east of China. They are said to be about 1200 in number, of which there are 400 very considerable. They form a principal division of that immense Indian Archipelago, which consists of so many thousand islands, some of which are the largest, and many of them the richest, in the world. The Philipines form the northernmost cluster of these islands, and were discovered in the year 1521 by the famous navigator Ferdinand Magellan, a Portuguese gentleman, who had served his native country both in the wars of Africa and in the East Indies; particularly under Albuquerque, the famous Portuguese general, who reduced Goa and Malacca to the obedience of that crown. Magellan having had a considerable share in those actions, and finding himself neglected by the government of Portugal, and even denied, as it is said, the small advance of a du at a month in his pay, left the court of Portugal in disgust, and offered his services to Charles V. then emperor of Germany and king of Spain, whom he convinced of the probability of discovering a way to the Spice Islands, in the East Indies, by the west; whereupon the command of five small ships being given him, he set sail from Seville, on the 10th of August 1519, and standing over to the coast of South America, proceeded southward to 52°, where he fortunately hit upon a strait, since called the *Strait of MAgellan*, which carried him into the Pacific Ocean or South Sea; and then steering northward, repassed the equator; after which he stretched away to the west, across that vast ocean, till he arrived at Guam, one of the Ladrones, on the 10th of March 1521; and soon after sailed to the westward, and discovered the Philipines, which he did on St Lazarus's day; and, in honour of that saint, he called them the *Archipelago of St Lazarus*. He took possession of them in the name of the king of Spain, but happened to be killed in a skirmish he had with the natives of one of them. His people,

however, arrived afterwards at the Moluccas, or Clove Islands, where they left a colony, and returned to Spain by the way of the Cape of Good Hope: being the first persons that ever sailed round the globe.— But there was no attempt made by the Spaniards to subdue or plant the Philippine Islands until the year 1564, in the reign of Philip II. son of Charles V. when Don Louis de Velasco, viceroy of Mexico, sent Michael Lopez Delagaspes thither with a fleet, and a force sufficient to make a conquest of these islands, which he named the *Philippines*, in honour of Philip II. then upon the throne of Spain; and they have remained under the dominion of that crown till taken by Sir William Draper. The Philippines are scarce inferior to any other islands of Asia in all the natural productions of that happy climate; and they are by far the best situated for an extensive and advantageous commerce. By their position, they form the centre of intercourse with China, Japan, and the Spice Islands; and whilst they are under the dominion of Spain, they connect the Asiatic and American commerce, and become a general magazine for the rich manufactures of the one and for the treasures of the other. Besides, they are well situated for a supply of European goods, both from the side of Acapulco and by the way of the Cape of Good Hope. In fact, they formerly enjoyed a traffic in some degree proportioned to the peculiar felicity of their situation; but the Spanish dominion is too vast and unconnected to be improved to the best advantage.— The spirit of commerce is not powerful in that people. The trade of the Philippines is thought to have declined; its great branch is now reduced to two ships, which annually pass between these islands and Acapulco in America, and to a single port of Manila in the island of Luconia.

Indeed the Spaniards appear by no means to be actuated by the spirit of industry; for, so far from improving the fine situation of these islands to the utmost, it happens, on the contrary, that the trade is hurtful to the mother country; for (to confine ourselves to Manila, with which they have most to do), instead of taking Spanish manufactures, they trade with the Chinese for spices, silks, stockings, Indian stuffs, callicoes, chintz, and many other articles: and with the Japanese for cabinets, and all sorts of lacquered ware; for all which they pay in gold or silver. All these commodities, together with what the islands produce in great quantities of wrought plate by the Chinese artificers, are collected at Manila, and transported annually in two ships to Acapulco in Mexico. Each of these ships is esteemed worth £.600,000 Sterling; and in the war which began in 1739, and which was not distinguished by such a series of wonderful successes as that which ended in 1763, the taking of one of the galleons which carry on the trade between Manila and America, was considered as one of the most brilliant advantages which the English gained. This trade is not laid open to all the inhabitants of Manila, but is confined by very particular regulations, somewhat analogous to those by which the trade of the register ships

from Cadiz to the West Indies is restrained. The Philippine Islands. The ships employed are all king's ships, commissioned and paid by him; and the tonnage is divided into a certain number of bales, all of the same size. These are divided among the convents at Manila, but principally the Jesuits (A), as a donation to support their missions, for the propagation of the Roman Catholic faith. Most of the religious are concerned in this trade, and sell to the merchants at a great price what room in the ship they are not to occupy. This trade is by a royal edict limited to a certain value, but it always exceeds it, each ship being generally worth 3,000,000 of dollars. The returns made from America are in silver, cochineal, sweetmeats, together with some European millenary ware for the women, and some strong Spanish wine. It is obvious, that the greatest part of the treasure remitted does not remain at Manila, but is dispersed over India for goods. Many strong remonstrances against this Indian trade to Mexico have been made to the court of Spain, wherein they urge, that the silk manufactories of Valencia and other parts of Spain, the linens from Cadiz, and their other manufactories, are hurt in their sale in Mexico and Peru, by the Chinese being able to afford them goods of the same sort cheaper than they are able; that were this trade laid open, the whole treasure of the New World would centre in Spain, or with European Merchants; but now it enriches only the Jesuits and a few private persons. Wise as these arguments are, the Jesuits and priests, versant in intrigue, and the most selfish set of men on earth, had interest enough at court to stop the effect.

At Cavite in this bay are a fort, a town, and a fine dock-yard, where these large galleons are built and repaired, and where they load and unload, together with all the other large ships that trade to this bay.

The principal of the Philippine islands are Luconia or Manila, Tandago or Samul, Masbate, Mindora, Luban, Paragoa, Panay, Leyte, Bohel, Sibul, Sogbu, Negros, St John, Xolo, and Mindanao. In most of these, the Spanish power prevails, and all are under the governor of Luconia; but there are some in which the nation has little authority, or even influence, such as Mindanao.

The inhabitants of these islands consist of Chinese, Ethiopians, Malays, Spaniards, Portuguese, Pintados or Painted People, and Mestees, a mixture of all these. Their persons and habits resemble those of the several nations whence they derive their original; only, it is observable, that the features of the blacks of these islands are as agreeable as those of the white people. There is not a soil in the world that produces greater plenty of all things for life; as appears by the multitude of inhabitants to be found in the woods and mountains, who subsist almost entirely by the fruits of the earth, and the venison they take. Nor can any country appear more beautiful; for there is a perpetual verdure, and buds, blossoms, and fruit, are found upon the trees all the year round, as well on the mountains as in the cultivated gardens. Vast quantities

(A) We do not know who has the Jesuits share since they were expelled the Spanish dominions.

Philippine
Islands.Philippine
Islands.

tics of gold are washed down from the hills by the rains, and found mixed with the sand of their rivers. There are also mines of other metals, and excellent load-stones found here; and such numbers of wild buffaloes, that a good huntsman on horseback, armed with a spear, will kill 10 or 20 in a day. The Spaniards take them for their hides, which they sell to the Chinese; and their carcases serve the mountaineers for food. Their woods also abound with deer, wild hogs, and goats. Of the last there is such plenty in one of these islands, that the Spaniards gave it the name of *Cabras*. Horses and cows have been likewise imported into these islands, from New Spain, China, and Japan, which have multiplied considerably; but the sheep that were brought over came to nothing. The trees produce a great variety of gums; one kind, which is the commonest, by the Spaniards called *brca*, is used instead of pitch; of the others some are medicinal, others odoriferous.

In those islands are monkeys and baboons of a monstrous bigness, that will defend themselves if attacked by men. When they can find no fruit in the mountains, they go down to the sea to catch crabs and oysters; and that the oysters may not close and catch their paws, they first put in a stone to prevent their shutting close; they take crabs by putting their tail in the holes where they lie, and when the crab lays hold of it they draw him out. There are also great numbers of civet-cats in some of the islands. The bird called *tavan*, is a black sea-fowl something less than a hen, and has a long neck; it lays its eggs in the sand by the sea side, 40 or 50 in a trench, and then covers them, and they are hatched by the heat of the sun. They have likewise the bird *saligan*, which builds her nest on the sides of rocks, as the swallows do against a wall; and these are the delicious *BIRDS-NESTS* so much esteemed, being a kind of jelly that dissolves in warm water.

The Spaniards have introduced several of the American fruits, which thrive here as well as in America; the cocoa or chocolate-nut particularly, which increases so that they have no occasion now to import it from Mexico. Here is also the *FOUNTAIN-TREE*, from which the natives draw water; and there is likewise a kind of cane, by the Spaniards called *vanuco*, which, if cut, yields fair water enough for a draught, of which there are plenty in the mountains, where water is most wanted.

These islands being hot and moist, produce abundance of venomous creatures, as the soil does poisonous herbs and flowers, which do not kill those who touch or taste them, but so infect the air, that many people die in the time of their blossoming.

The orange, lemon, and several other trees, bear twice a year. A sprig, when planted, becomes a tree and bears fruit in a year's time; so that without any hyperbole it may be affirmed, that a more luxuriant verdant soil can scarcely be conceived. The woods are filled with old, large, and lofty trees, and such as yield more sustenance to man than is to be found in almost any other part of the world. These islands, however, besides their other inconveniences, of which they have many, are very subject to earthquakes, which often prove very fatal. See *MANILA*.

PHILIPPINES, a religious society of young women at Rome, so called from their taking St Philip de Neri for their protector. The society consists of 100 poor girls, who are brought up till they are of age to be married, or become nuns, under the direction of some religious women, who teach them to read, write, and work, and instruct them in the duties of Christianity. They wear a white veil, and a black cross on their breasts. See *MACEDONIA*.

PHILIPPISTS, a sect or party among the Lutherans; the followers of Philip Melancthon. He had strenuously opposed the Ubiquists, who arose in his time; and the dispute growing still hotter after his death, the university of Wittemberg, who espoused Melancthon's opinion, were called by the Flacians, who attacked it, *Philippists*.

PHILIPS (Fabian), was author of several books relating to ancient customs and privileges in England. He was born at Prestbury in Gloucestershire, September 28th, 1601. When very young, he spent some time in one of the Inns of Chancery; and went from thence to the Middle-Temple, where he became learned in the law. In the civil wars he was a bold assertor of the king's prerogative; and was so passionate a lover of Charles I. that two days before that illustrious monarch was beheaded, he wrote a protestation against the intended murder, and caused it to be printed, and affixed to posts in all public places. He likewise published in 1649, 4to, a pamphlet intitled, "*Veritas Inconclusa*;" or King Charles I. no Man of Blood, but a Martyr for his People:" which was reprinted in 1660, 8vo. In 1653, when the courts of justice at Westminster, especially the Chancery, were voted down by Oliver's parliament, he published, "Considerations against the dissolving and taking them away:" for which he received the thanks of William Lenthall, Esq; speaker of the late parliament, and of the keepers of the liberties of England. He was for some time filazer for London, Middlesex, Cambridge-shire, and Huntingdonshire; and spent much money in searching records, and writing in favour of the royal prerogative. The only advantage he received for this attachment to the royal cause was, the place of one of the commissioners for regulating the law, worth L. 200 *per annum*, which only lasted two years. After the Restoration of Charles II. when the bill for taking away the tenures was depending in parliament, he wrote and published a book to show the necessity of preserving them, intitled, "*Tenenda non Tollenda*:" or, the necessity of preserving tenures *in capite*, and by Knight's-service, which, according to their first institution, were, and are yet, a great part of the *salus populi*, &c. 1660," 4to. In 1663 he published, "The antiquity, Legality, Reason, Duty, and Necessity of Pre-emption and Pourveyance for the King," 4to; and afterwards many other pieces upon subjects of a similar kind. He assisted Dr Bates in his "*Elenchus Motuum*;" especially in searching the records and offices for that work. He died November 17th, 1690, in his 89th year; and was buried near his wife in the church of Twyford in Middlesex. He was a man well acquainted with records and antiquities; but his manner of writing is neither close nor well digested. He published a political pamphlet in 1681, intitled,

Phillips.

intituled, "*Urfa Major et Minor*; showing that there is no such Fear, as is factitiously pretended, of Popery and arbitrary Power."

PHILIPS (Ambrose), an English poet, was descended from a very ancient and considerable family of that name in Leicestershire. He received his education at St John's college, Cambridge; during his stay at which university, he wrote his pastorals, which acquired him at the time so high a reputation. His next performance was, *The Life of Archbishop Williams*, written, according to Mr Cibber, to make known his political principles, which in the course of it he had a free opportunity of doing, as the archbishop, who is the hero of his work, was a strong opponent to the high church measures.

When he quitted the university, and came to London, he became a constant attendant at, and one of the wits of, Button's coffee-house, where he obtained the friendship and intimacy of many of the celebrated geniuses of that age, more particularly of Sir Richard Steele, who, in the first volume of his *Tatler*, has inserted a little poem of Mr Phillips's, which he calls a *Winter Piece*, dated from Copenhagen, and addressed to the earl of Dorset, on which he bestows the highest encomiums; and indeed, so much justice is there in these his commendations, that even Mr Pope himself, who had a fixed aversion for the author, while he affected to despise his other works, used always to except this from the number.

The first dislike Mr Pope conceived against Mr Phillips, proceeded from that jealousy of fame which was so conspicuous in the character of that great poet; for Sir Richard Steele had taken so strong a liking to the pastorals of the latter, as to have formed a design for a critical comparison of them with those of Pope, in the conclusion of which the preference was to have been given to Phillips. This design, however, coming to Mr Pope's knowledge, that gentleman, who could not bear a rival near the throne, determined to ward off this stroke by a stratagem of the most artful kind; which was no other than taking the same task on himself; and, in a paper in the *Guardian*, by drawing the like comparison, and giving a like preference, but on principles of criticism apparently fallacious, to point out the absurdity of such a judgment. However, notwithstanding the ridicule that was drawn on him in consequence of his standing as it were in competition with so powerful an antagonist, it is allowed, that there are, in some parts of Phillips's pastorals, certain strokes of nature, and a degree of simplicity that are much better suited to the purposes of pastoral, than the more correctly turned periods of Mr Pope's versification. Mr Phillips and Mr Pope being of different political principles, was another cause of enmity between them; which arose at length to so great a height, that the former, finding his antagonist too hard for him at the weapon of wit, had even determined on making use of a rougher kind of argument; for which purpose he even went so far as to hang up a rod at Button's for the chastisement of his adversary whenever he should come thither; which, however, Mr Pope declining to do, avoided the *argumentum baculinum* in which he would, no doubt, have found himself on the weakest side of the question. Our author also wrote

Phillips.

several dramatical pieces; *The Briton*, *Distressed Mother*, and *Humphrey duke of Gloucester*; all of which met with success, and one of them is at this time a standard of entertainment at the theatres, being generally repeated several times in every season. Mr Phillips's circumstances were in general, through his life, not only easy but rather affluent, in consequence of his being connected, by his political principles, with persons of great rank and consequence. He was connected with Dr Hugh Boulter, afterwards archbishop of Armagh, the right honourable Richard West, Esq; lord chancellor of Ireland, the reverend Mr Gilbert Burnet, and the reverend Mr Henry Stevens, in writing a series of papers called the *Free Thinker*, which were all published together by Mr Phillips, in three volumes in 12mo.

In the latter part of Queen Anne's reign, he was secretary to the Hanover club, who were a set of noblemen and gentlemen who had formed an association in honour of that succession, and for the support of its interests, and who used particularly to distinguish in their toasts such of the fair sex as were most zealously attached to the illustrious House of Brunswick. Mr Phillips's station in this club, together with the zeal shown in his writings, recommended him to the notice and favour of the new government. He was, soon after the accession of king George I. put into the commission of the peace, and appointed one of the commissioners of the lottery. And, on his friend Dr Boulter's being made primate of Ireland, he accompanied that prelate across St George's channel, where he had considerable preferments bestowed on him and was elected a member of the House of Commons there, as representative for the county of Armagh. At length, having purchased an annuity for life of 400 l. *per annum*, he came over to England some time in the year 1748; but having a very bad state of health, and being moreover of an advanced age, he died soon after, at his lodgings near Vauxhall, in Surry.

"Of his personal character (says Dr Johnson) all I have heard is, that he was eminent for bravery, and skill in the sword, and that in conversation he was solemn and pompous." He is somewhere called *Quaker Phillips*, but, however, appears to have been a man of integrity; for the late Paul Whitehead relates, that when Mr Addison was secretary of state, Phillips applied to him for some preferment, but was coolly answered, "that it was thought that he was already provided for, by being made a justice for Westminster." To this observation our author, with some indignation, replied, "Though poetry was a trade he could not live by, yet he scorned to owe subsistence to another which he ought not to live by."

The following anecdote is told of our author by Dr Johnson: "At a coffee-house, he (Phillips) was discoursing upon pictures, and pitying the painters, who, in their historical pieces, always draw the same sort of *sky*. "They should travel (said he), and then they would see that there is a different *sky* in every country, in England, France, Italy, and so forth." "Your remark is just (said a grave gentleman who sat by), I have been a traveller, and can testify what you observe is true; but the greatest variety of *skies* that I found was in Poland." "In Poland, Sir? (says Phillips)." "In Poland, Sir?" (says Phillips.)

Philips.

lips)." "Yes, in Poland; for there is *Sobieſky*, and *Sabunſky*, and *Jablonſky*, and *Podebraſky*, and many more *ſkies*.

PHILIPS (Catharine), a very ingenious lady, the daughter of Mr John Fowler merchant, was born at London in January 1631, and educated at a ſchool at Haekney. She married James Philips of the priory of Cardigan, Eſq; and went with the viſcounteſs of Dungannon into Ireland, where ſhe tranſlated Corneille's tragedy of Pompey into Engliſh, which was ſeveral times acted there with great applauſe.

She tranſlated alſo the four firſt acts of Horace, another tragedy of Corneille, the fifth being done by Sir John Denham. This excellent and amiable lady, for ſuch it ſeems ſhe was, died of the ſmall-pox in London, the 22d of June 1664, much and juſtly regretted; "having not left (ſays Langbaine) any of her ſex her equal in poetry.—She not only equalled (adds he) all that is reported of the poetreſſes of antiquity, the Lesbian Sappho and the Roman Sulpitia, but juſtly found her admirers among the greateſt poets of our age." Cowley wrote an ode upon her death. Dr Jeremy Taylor had addreſſed to her his "Meaſures and offices of Friendſhip:" the ſecond edition of which was printed in 1657, 12mo. She aſſumed the name of *Orinda*. In 1667, were printed, in folio, "Poems by the moſt deſervedly admired Mrs Catharine Philips, the matchleſs *Orinda*. To which is added, *monſieur Corneille's Pompey* and *Horace, tragedies*. With ſeveral other tranſlations from the French;" and her picture before them, engraven by Faithorne. There was likewiſe another edition in 1678, folio; in the preface of which we are told, that "ſhe wrote her familiar letters with great facility, in a very fair hand, and perfect orthography; and if they were collected with thoſe excellent diſcourſes ſhe wrote on ſeveral ſubjects, they would make a volume much larger than that of her poems." In 1705, a ſmall volume of her letters to Sir Charles Cotrel were printed under the title of "Letters from *Orinda* to *Poliarchus*. The editor of theſe letters tells us, that "they were the effect of an happy intimacy between herſelf and the late famous *Poliarchus*, and are an admirable pattern for the pleaſing correſpondence of a virtuous friendſhip. They will ſufficiently inſtruct us, how an intercourſe of writing between perſons of different ſexes ought to be managed with delight and innocence; and teach the world not to load ſuch a commerce with cenſure and detraction, when it is removed at ſuch a diſtance from even the appearance of guilt."

PHILIPS (John), an eminent Engliſh poet, was born in 1676. He was educated at Wincheſter and Oxford, where he became acquainted with Milton, whom he ſtudied with great application, and traced in all his ſucceſſful tranſlations from the ancients. The firſt poem which diſtinguiſhed our author, was his *Splendid Shilling*, which is in the *Tatler* ſtyled the *fineſt burleſque poem in the Engliſh language*. His next was intitled *Blenheim*, which he wrote at the requeſt of the earl of Oxford, and Mr Henry St John, afterwards Lord Bolingbroke, on the victory obtained there by the duke of Marlborough in 1704. It was published in 1705; and the year after he finiſhed another poem upon cyder, the firſt book of which had been

Philips.

written at Oxford. It is on the model of Virgil's *Georgics*, and is a very excellent piece. We have no more of Mr Philips but a Latin ode to Henry St John, Eſq; which is eſteemed a maſter-piece. He was contriving greater things; but illneſs coming on, he was obliged to drop every thing but the care of his health. This care, however, did not ſave him; for, after lingering a long time, he died at Hereford, Feb. 15, 1708, of a conſumption and athma, before he had reached his 33d year. He was interred in the cathedral of that city with an inſcription over his grave; and had a monument erected to his memory in Weſtminſter-abbey by Sir Simon Harcourt, afterwards lord-chancellor, with an epitaph upon it written by Dr Atterbury, though commonly aſcribed to Dr Friend. He was one of thoſe few poets, whoſe muſe and manners were equally excellent and amiable; and both were ſo in a very eminent degree.

Dr Johnſon obſerves, that "Philips has been always praiſed, without contradiction as a man modeſt, blameleſs, and pious; who bore a narrow fortune without diſcontent, and tedious and painful maladies without impatience; beloved by thoſe that knew him, but not ambitious to be known. He was probably not formed for a wide circle. His converſation is commended for its innocent gaiety, which ſeems to have flowed only among his intimates; for I have been told, that he was in company ſilent and barren, and employed only upon the pleaſures of his pipe. His addiction to tobacco is mentioned by one of his biographers, who remarks, that in all his writings except *Blenheim*, he has found an opportunity of celebrating the fragrant ſmoke. In common life, he was probably one of thoſe who pleaſe by not offending, and whoſe perſon was loved, becauſe his writings were admired. He died honoured and lamented, before any part of his reputation had withered, and before his patron St John had diſgraced him. His works are few. The *Splendid Shilling* has the uncommon merit of an original deſign, unleſs it may be thought precluded by the ancient *Centos*. To degrade the ſounding words and ſtately conſtruction of Milton, by an application to the loweſt and moſt trivial things, gratifies the mind with a momentary triumph over that grandeur which hitherto held its captives in admiration; the words and things are preſented with a new appearance, and novelty is always grateful where it gives no pain. But the merit of ſuch performances begins and ends with the firſt author. He that ſhould again adopt Milton's phraſe to the groſs incidents of common life, and even adapt it with more art, which would not be difficult, muſt yet expect but a ſmall part of the praiſe which Philips has obtained; he can only hope to be conſidered as the repeater of a jeſt.

"There is a Latin ode written to his patron St John, in return for a preſent of wine and tobacco, which cannot be paſſed without notice. It is gay and elegant, and exhibits ſeveral artful accommodations of claſſic expreſſions to new purpoſes. It ſeems better turned than the odes of Hannes. To the poem on cyder, written in imitation of the *Georgics*, may be given this peculiar praiſe, that it is grounded in truth; that the precepts which it contains are exact and juſt; and that it is therefore at once a book of entertainment and of ſcience. This I was told by Müller, the great

Philips
||
Philistines.

great gardener and botanist, whose expression was, that 'there were many books written on the same subject in prose, which do not contain so much truth as that poem.' In the disposition of his matter, so as to intersperse precept, relating to the culture of trees, with sentiments more generally pleasing, and in easy and graceful transitions from one subject to another, he has very diligently imitated his master; but he unhappily pleased himself with blank verse, and supposed that the numbers of Milton which impress the mind with veneration, combined as they are with subjects of inconceivable grandeur, could be sustained by images which at most can rise only to elegance. Contending angels may shake the regions of heaven in blank verse; but the flow of equal measures and the embellishment of rhyme, must recommend to our attention the art of engraving, and decide the merit of the red-streak and pearmain. What study could confer, Philips had obtained; but natural deficiency cannot be supplied. He seems not born to greatness and elevation. He is never lofty, nor does he often surprise with unexpected excellence: but perhaps to his last poem may be applied what Tully said of the work of Lucretius, that 'it is written with much art, though with few blazes of genius.'

It deserves to be remarked, that there were two poets of both the names of our author, and who flourished in his time. One of them was Milton's nephew, and wrote several things, particularly some memoirs of his uncle, and part of Virgil Travestied. The other was the author of two political farces, which were both printed in 1716; 1. The Earl of Marr married, with the Humours of Jocky the Highlander. 2. The Pretender's Flight; or a Mock Coronation, with the Humours of the facetious Harry St John.

PHILIPSBURG, is an imperial town of Germany, in the circle of the Upper Rhine. It is very strong, and looked upon as one of the bulwarks of the empire. It is seated in a morass, and fortified with seven bastions and several advanced works. The town belongs to the bishop of Spire, but all the works and the fortifications to the empire. It has been several times taken and retaken, particularly by the French in 1734, when the duke of Berwick was killed at the siege; but it was rendered back the year following, in consequence of the treaty of Vienna. It is seated on the river Rhine, over which there is a bridge seven miles south of Spire, 22 south-east of Worms, and 40 north-east of Straßburg. E. Long. 8 33. N. Lat. 49. 12.

PHILISTÆA (anc. geog.), the country of the Philistines (Bible); which lay along the Mediterranean, from Joppa to the boundary of Egypt, and extending to inland places not far from the coast. *Palestini*, the people; *Palestina*, the country (Josephus); Afterwards applied to the whole of the Holy Land and its inhabitants. *Philistæi*, the people (Septuagint *Philistini* (Vulgate); the *Caphtorim* and *Philistim*, originally from Egypt, and descendants of Cham (Moses). Expelled and destroyed the Hivites the ancient inhabitants, and occupied their country; that is, the region which retained the name of *Philistim*, in which that of *Caphtorim* was swallowed up.

PHILISTINES, were the ancient inhabitants of Palestine, well known in sacred history. These people are sometimes called in Scripture *Cherethites* and *Caphtorims*

the earlier part of their history is, like that of Philistines. most other nations, very obscure and uncertain. The authors of the universal History tell us, that they were descended from the *Castuhim* partly, and partly from the *Caphtorim*, both from the loins of Mizraim the son of Ham, the son of Noah. Moses tells us (Deut. xi. 23.), that they drove out the *Avim* or *Avites* even to *Azzah* or *Gazah*, where they settled; but when this happened cannot be determined. On the whole, however, our learned authors are clearly of opinion, that the *Castuhim* and *Caphtorim*, from whom the *Philistines* are descended, came originally from Egypt; and called the country which they had conquered by their own name (See *PALESTINE*). Many interpreters, however, think, that *Caphtor* was but another name for *Cappadocia*, which they imagine to have been the original country of the *Philistines*. But *Father Calmet*, in a particular dissertation prefixed to the first book of *Samuel*, endeavours to show that they were originally of the isle of *Crete*. The reasons which led him to think that *Caphtor* is the isle of *Crete* are as follow: The *Philistines* were strangers in *Palestine* as appears in various parts of Scripture; such as *Gen. x. 14.* *Deut. ii. 23.* *Jer. xlvii. 4.* and *Amos ix. 7.* whence the *Septuagint* always translate this name *Strangers*. Their proper name was *Cherethims* for *Ezekiel* (xxv. 16.), speaking against the *Philistines*, has these words, "I will stretch out my hand upon the *Philistines*, and I will cut off the *Cherethims*, and destroy the remnant of the sea-coast." *Zephaniah* (ii. 5.), inveighing against the same people, says, "Wo unto the inhabitants of the sea-coasts, the nation of the *Cherethites*." And *Samuel* (Book I. xxx. 14.) says, that the *Amalekites* made an irruption into the country of the *Cherethites*, that is to say, of the *Philistines*, as the sequel of the discourse proves. And afterwards the kings of *Judah* had foreign guards called the *Cherethites* and *Pelethites*, who were of the number of the *Philistines* (2 *Sam. xv. 18.* The *Septuagint*, under the name *Cherethites*, understood the *Cretans*; and by *Cherith* they understood *Crete*. Besides the Scripture says, that the *Philistines* came from the isle of *Caphtor*. Now we see no island in the Mediterranean wherein the marks whereby the Scripture describes *Caphtor* and *Cherethim* agree better than in the isle of *Crete*. The name *Cretim* or *Cherethim* is the same with that of *Cretensis*. The *Cretans* are one of the most ancient and celebrated people which inhabited the islands of the Mediterranean. They pretended to have been produced originally out of their own soil. This island was well peopled in the time of the Trojan war. *Homer* calls it the island with a hundred cities. The city of *Gaza* in *Palestine* went by the name of *Minoa* (*Suph. Bizant. in Gaza*), because *Minos* king of *Crete* coming into that country, called this ancient city by his own name.

Herodotus acknowledges that the *Cretans* were originally all barbarians, and did not come from Greece. *Homer* says, that a different language was spoken in the isle of *Crete*; that there were Greeks there, true or ancient *Cretans* *Pelasgians*, &c. The ancient *Cretans* are the same as the *Cherethites*, the *Pelasgians* as the *Philistines* or *Pelethites* of the Scripture: their language was the same with that of the *Canaanites* or *Phœnicians*, that is, Hebrew: they were descended, as

well

Philistines, well as Canaan, from Ham, by Mizraim (Gen. x. 6, 13, 14.) The manners, arms, religion, and gods of the Cretans and Philistines were the same. The arms of the one and the other were bows and arrows. Dagon the god of the Philistines was the same as the Diæmona of the Cretans.

Whether these arguments are convincing, it is not for us to determine; but Wells does not think they are, as he is of the same opinion with the authors of the Universal history, who say, that *Captus*, the name of an old city of Egypt, is a corruption of the ancient *Cashtor*. It is not, however, of great importance to determine whether they came from Crete, from Cappadocia, or from Egypt: they had certainly been a considerable time in the Land of Canaan, when Abraham arrived there in the year of the world 2083. They were then a very powerful people, were governed by kings, and in possession of several considerable cities. The race of kings then in power were honoured with the title of *Abimelech*. This race, however, was but of short duration; for their monarchy became an aristocracy of five lords, who were, as far as we can discover, partly independent of each other, though they acted in concert for the common cause. This form of government was again succeeded by another race of kings, distinguished by the title of *Abib*, though they also bore that of *Abimelech*. The kings were always under great limitations. The Philistines appear to have been a very warlike people, industrious, and lovers of freedom; they did not circumcise, and in the early periods of their history held adultery in the greatest abhorrence. "Their character (say the authors of the Universal History) must be considered at different periods; for we may say they were not always the same people. In the days of Abraham and Isaac, they were without all doubt a righteous and hospitable nation: but afterwards a revolution in government, religion, and morals, may have ensued. From thenceforward they became like other idolatrous nations; the same enormities crept in and prevailed among them. They are constantly mentioned in Scripture as strangers; and though, possessed of a most considerable part of the Land of Promise, yet God would never suffer them to be driven out, they being Egyptians by descent, and not original natives, whose land only was promised to Abraham and his seed. Their arrogance and ambition were great; and so irreconcilable was their enmity (A) to the Israelites, that one would be almost tempted to think they were created on purpose to be a thorn in their sides; for though the hand of God was evidently against them several times, and particularly when they detained the ark, yet they hardened their hearts, and closed their eyes against conviction. They seem to have entertained a very fond veneration for their deities, in which they persisted, tho'

Vol. XIV.

they were eye-witnesses of the same. (See also Philistines which held them in the presence of the Lord, &c.) It may, they were so biased in their favour, that they might that their gods might prevail against those who were in soulating a manner put them to shame and disgrace. They were much addicted to trade; and by considering their situation, they may have excelled from the beginning; but, by the accession of the fugitive Egyptians in David's time, they rose to so great a reputation as merchants, that the Greeks, if I am not mistaken, called all the country bordering on the *Palæstina*. Their language was not so different from that spoken by the Hebrews as to cause any difficulty for them to converse together, as will be perceived by their intercourse with Abraham and Isaac; so that, in all this region, perhaps with some variation of dialect, they had so common the arts and sciences in common with the most learned and ingenious among their contemporaries, and perhaps some of them in greater perfection. They had giants among them, but whether they were originally of the breed of the Anakims, who retired hither when they were expelled from Hebron, or were sprung from accidental births, is not easily determined. We must not forget, that the invention of the bow and arrow is ascribed to this people.

"Their religion was different at different times; under their first race of kings, they used the same rites with the Hebrews. Abimelech, in the sin he had committed with Sarah, through Abraham's timidity, was favoured with a divine admonition from God; and, by his speech and behaviour at that time, it seems as if he had been used to converse with the Deity. In after-times, they erred into endless superstitions, and different kinds of idolatry; each of the principal or five cities seemed to have had an idol of its own. Marna, Marnis, or Marnash, was worshipped at Gaza, and is said to have migrated into Crete, and to have become the Cretan Jupiter. Dagon was worshipped at Azotus: he seems to have been the greatest, the most ancient, and most favourite god they had; to which may be added, that he perhaps subsisted the longest of any that did not straggle out of the country. To him they ascribed the invention of bread-corn, or of agriculture, as his name imports. We cannot enter into the common notion of his being represented as a monster, half man half fish; nor frequently into another almost as common, that he is the same with the Syrian goddess Derceto, who, we are told, was represented under some such mixed form. Our opinion is, that this idol was in shape wholly like a man; for we read of his head, his hands, and his feet. He stood in a temple at Azotus, and had priests of his own who paid him a very constant attendance.

(A) "From a passage in Chronicles, it is guessed to have been of very ancient date; where it is said, that 'the men of Gath slew the Children of Ephraim, who would have taken their cattle from them.' This incident is nowhere else to be found; and there are various notions concerning the sense in which we must take this passage. As to the time of the transaction, most people allow it to have been while the children of Israel were sojourners in Egypt. It plainly appears, by the next verse, that Ephraim himself was living at that period. The Targum supposes his children miscomputed the time they were to serve in Egypt, and began too early an attempt upon their Promised Land."

Philistines. Next to Dagon was Baalzebub the God of Ekron. In the text of the New Testament he is called *Beelzebub*, and the *prince of devils*. His name is rendered *lord of flies*; which by some is held to be a mock appellation bestowed on him by the Jews; but others think him so styled by his worshippers, as Hercules Apomylos, and others, were, from his driving those insects away; and urge, that Ahaziah, in his sickness, would scarcely have applied to him, if his name had carried in it any reproach. But it must be remembered, it is the sacred historian that makes use of that contemptuous term in derision; whereas the idolatrous monarch, who was one of his votaries, might call him by his common name, supposed to have been *Baal-zeboob*, 'the lord of armies,' or *Baal-shamim*, 'lord of heaven,' or some other bordering on Baal-zebub. How, or under what form he was represented, is uncertain: some place him on a throne, and attire him like a king; others paint him as a fly. Not to dwell on this obscurity, it appears that he became an oracle of the highest repute for omniscience and veracity; that he had priests of his own; and that he, in the middle times at least, was much sought after by those who were anxious about futurity. Derceto we take certainly to have been the goddess of Ascalon; but we are supported by profane authority, without the least countenance from Scripture. Gath is seemingly the only city of all the five unprovided with a deity; wherefore, as the Scripture declares, that Ashtaroth, or Astarte, was worshipped by this people, we are ready to place her at Gath, and the rather, as this of all their cities may have had most communication with Sidon. To speak in general concerning their religious rites and ceremonies, which is all we can do, they seem to have erected very large and spacious temples, or very wide halls, for the celebration of their solemn seasons and festivals (for such they surely had); their religious offices were attended with much pomp, and a great concourse from all parts; and they presented their gods with the chief part of their spoil, and carried them about with them when they went to war. We do not find in Scripture that they sacrificed their children; and yet the Curetes (B) are said to be their descendants."

With respect to the history of this extraordinary people, we find from the above extract, that they were not comprehended in the number of nations devoted to extermination, and whose territory the Lord had abandoned to the Hebrews; nor were they of the cursed seed of Canaan. However, Joshua did not forbear to give their lands to the Hebrews, and to set upon them by command from the Lord, because they possessed a country which was promised to the people of God (Josh. xv. 45—47. and xiii. 2, 3.) But these conquests of Joshua must have been ill maintained, since under the Judges, under Saul, and at the beginning of the reign of David, the Philistines oppressed the Israelites. True it is, Shamgar, Samson, Samuel, and Saul, made head against them,

but did not reduce their power; and they continued independent down to the reign of David, who subjected them to his government.

They continued in subjection to the kings of Judah down to the reign of Jehoram, son of Jehoshaphat; that is, for about 246 years. However Jehoram made war against them, and probably reduced them to his obedience again; because it is observed in Scripture, that they revolted again from Uzziah; and that the prince kept them to their duty during the time of his reign (2 Chr. xxi. 16. and xxvi. 6, 7.) During the unfortunate reign of Ahaz, the Philistines made great havoc in the territories of Judah; but his son and successor Hezekiah subdued them (2 Chr. xxviii. 18. and 2 Kings xviii. 8.) Lastly, they regained their full liberty under the latter kings of Judah; and we may see by the menaces denounced against them by the prophets Isaiah, Amos, Zephaniah, Jeremiah, and Ezekiel, that they brought a thousand hardships and calamities upon the children of Israel: for which cruelties God threatened to punish them. Sardanapalus besieged Ashdod or Azoth, and took it (Isa. xx. 1.) And according to Herodotus, Psammeticus king of Egypt took the same city, after a siege of 29 years. There is great probability, that Nebuchadnezzar, when he subdued the Ammonites, Moabites, Egyptians, and other nations, bordering upon the Jews, reduced also the Philistines. After this, they fell under the dominion of the Persians; then under that of Alexander the Great, who destroyed the city of Gaza, the only city of Phœnicia that durst oppose him. After the persecution of Antiochus Epiphanes, the Asmonæans subjected under their obedience several cities of the Philistines; and Tryphon gave to Jonathan Maccabæus the government of the whole coast of the Mediterranean, from Tyre as far as Egypt, which included all the country of the Philistines.

PHILLYREA, MOCK PRIVET; a genus of the monogynia order, belonging to the diandria class of plants. Each flower contains two males and one female. Some say there are seven species, all of them shrubby plants, and natives of France or Italy. Others reckon only three species, which are as follow:

1. *Phillyrea media*; the oval leaved phillyrea or mock privet, or the medial leaved phillyrea, a tall evergreen shrub, native of the south of Europe. 2. *Phillyrea latifolia*; the broad-leaved phillyrea or mock privet a tall evergreen shrub, native of the south of Europe. 3. *Phillyrea angustifolia*; the narrow-leaved phillyrea or mock privet, a deciduous shrub, native of Spain and Italy.

1. The first has three varieties, viz. The first is the common smooth-leaved phillyrea. This plant grows to be 12 or 14 feet high, and the branches are very numerous. The older branches are covered with a dark brown bark, but the bark on the young shoots is of a fine green colour. They are oval, spear-shaped, and grow opposite, by pairs, on strong short footstalks.

The

(B) "The Curetes sacrificed their children to Saturn; and from the similitude this name bears to Chæretides or Philistines, it has been advanced that they are the same people; but as we have no warrant for saying the Philistines practised so barbarous and unnatural a custom, we may venture to pronounce, that they learned it not from them, but borrowed it elsewhere."

dening.

Phillyrea. The flowers are produced in clusters from the wings of the young branches. They are small, and of a kind of greenish-white colour; they appear in March, and are succeeded by berries, which are first green, then red, and black in the autumn when ripe. The second variety is the privet leaved phillyrea, which grows to be 10 or 12 feet high, and the branches of which are covered with a brown bark. The leaves a little resemble the privet; they are of a fine green colour, and grow by pairs on the branches. They are of a lanceolate figure, and their edges are entire or nearly so; for some signs of serratures sometimes appear. The flowers grow like others in clusters in March. They are whitish, and are succeeded by small black berries. The third variety, or the olive-leaved phillyrea, is the most beautiful of all the sorts. It will grow to be about 10 or 12 feet high; and the branches, which are not numerous, spread abroad in a free easy manner, which may not improperly be said to give the tree a fine air. They are long and slender, and are covered with a light brown bark; and on these the leaves stand opposite by pairs at proper intervals on short footstalks. They resemble those of the olive-tree, and are of so delightful a green as to force esteem. Their surface is exceeding smooth, their edges are entire, and the membrane of a thickish consistence. The flowers are small and white, and like the other sorts make no show. They are succeeded by single roundish berries.

2. The broad-leaved phillyrea will grow to be about 12 feet high. The branches seem to be produced stronger and more upright than those of the former species. The bark is of a grey colour, spotted with white, which has a pretty effect; and the leaves grow opposite by pairs. They are of a heart-shaped oval figure of a thick consistence, and a strong dark-green colour. Their edges are sharply serrated, and they stand on short strong footstalks. The flowers grow from the wings of the leaves in clusters in March. They are of a kind of greenish-white colour, make no show, and are succeeded by small round black berries. There are also three varieties of this species, viz. the ilex-leaved phillyrea, the prickly phillyrea, and the olive phillyrea with slightly serrated edges.

3. The narrow-leaved phillyrea is of lower growth, seldom rising higher than 8 or 10 feet. The branches are few and slender, and they also are beautifully spotted with grey spots. The leaves, like the others, stand opposite by pairs. They are long and narrow, spear-shaped, and undivided, of a deep green colour, and of a thick consistence. Their edges are entire, and they also stand on short footstalks. The flowers, like the others, make no show. They are whitish, and grow in clusters from the wings of the branches, in March; and are succeeded by small round black berries. The varieties of this species are, the rosemary phillyrea, lavender phillyrea, striped phillyrea, &c.

This vegetable is to be propagated by seeds or layers. 1. By seeds. These ripen in the autumn, and should be sown soon after. The mould must be made fine; and if it is not naturally sandy, if some drift sand be added, it will be so much the better. The seeds for the most part remain until the second spring before they come up; and if they are not sown soon after they are ripe, some will come up even the third spring after. They must be sown about an inch deep; and

during the following summer should be kept clear from weeds. After they are come up, the same care must be observed, and also watering in warm weather; and if the beds are hooped, and the plants shaded in the hottest season, they will be so much the better for it. However, at the approach of winter they must be hooped, and the beds covered with mats in the hardest frosts, otherwise there will be danger of losing the whole crop; for these trees, though they are very hardy when grown tolerably large, are rather tender whilst seedlings. It will be proper to let them remain in the seed beds with this management for two summers; and then waiting for the first autumnal rain, whether in September or October (and having prepared a spot of ground), they should at that juncture be planted out, and this will occasion them immediately to strike root. The distance they should be planted from each other need not be more than a foot, if they are not designed to remain long in the nursery. If there is a probability of their not being wanted for some years, they should be allowed near double that distance; and every winter the ground in the rows should be well dug, to break their roots, and cause them to put out fresh fibres otherwise they will be in danger of being lost when brought into the shrubbery quarters. 2. By layers they will easily grow. The autumn is the best time for this operation, and the young shoots are fit for the purpose. The best way of layering them is by making a slit at the joint; though they will often grow well by a twist being only made. When the gardener chooses the method of twisting a young branch for the layers, he must be careful to twist it about a joint so as only to break the bark; for if it is too much twisted, it will die from that time, and his expectations wholly vanish. But if it be gently twisted with art and care, it will at the twisted parts be preparing to strike root, and by the autumn following, as well as those layers that had been slit, will have good roots; the strongest of which will be fit for planting where they are wanted to remain, whilst the weaker and worst-rooted layers may be planted in the nursery-ground like the seedlings, and treated accordingly.

PHILO, an ancient Greek writer, was of a noble family among the Jews, and flourished at Alexandria during the reign of Caligula. He was the chief of an embassy sent to Rome about the year 42, to plead the cause of the Jews against Apion, who was sent by the Alexandrians to charge them with neglecting the honours due to Caesar. Caligula, however, would not allow him to speak, and behaved to him in such a manner that Philo was in considerable danger of losing his life. Others again tell us that he was heard; but that his demands were refused. He afterwards went to Rome in the reign of Claudius; and then, Eusebius and Jerome inform us, he became acquainted with St Peter, with whom he was on terms of friendship. Photius adds, that he became a Christian, and afterwards, from some motive of resentment, renounced it. Great part of this however, is uncertain, for few believe that St Peter was at Rome so early as the reign of Claudius, if he ever was there at all.

Philo was educated at Alexandria, and made very great progress in eloquence and philosophy. After the fashion of the time, he cultivated, like many of his nation and faith, the philosophy of Plato, whose prin-

Philo.
Philoetes.

ciples he so thoroughly imbibed, and whose manner he so well imitated, that it became a common saying, "Aut Plato philonizat, aut Philo platonizat." Josephus says, he was a man "eminent on all accounts;" and Eusebius describes him, "copious in speech, rich in sentiments, and sublime in the knowledge of holy writ." He was, however, so much immersed in philosophy, particularly the Platonic, that he neglected the Hebrew language, and the rites and customs of his own people. Scaliger says, that Philo "knew no more of Hebrew and Syriac than a Gaul or a Scythian." Grotius is of opinion, that "he is not fully to be depended on, in what relates to the manners of the Hebrews;" and Cudworth goes further; for "though a Jew by nation (says he), he was yet very ignorant of Jewish customs." Fabricius thinks differently; for though he allows some inadvertencies and errors of Philo with regard to these matters, yet he does not see a sufficient foundation on which to charge so illustrious a doctor of the law with ignorance. He allows, however, that Philo's passion for philosophy had made him more than half a Pagan; for it led him to interpret the whole law and the prophets upon Platonic ideas; and to admit nothing as truly interpreted which was not agreeable to the principles of the academy. Besides, this led him farther; he turned every thing into allegory, and deduced the darkest meanings from the plainest words. This most pernicious practice ORIGEN, it is known, imitated, and exposed himself by it to the scoffs of Celsus and of Porphyry. Philo's writings abound with high and mystical, new and subtle, far-fetched and abstrused notions; and indeed the doctrines of Plato and Moses are so promiscuously blended, that it is not an easy matter to assign to each his principles. There are certainly, however, in his works many excellent things. Though he is continually Platonizing and allegorizing the Scriptures, he abounds with fine sentiments and lessons of morality; and his morals are rather the morals of a Christian than of a Jew. History, together with his own writings, give us every reason to believe that he was a man of great prudence, constancy, and virtue.

His works were first published in Greek by Turnebus at Paris 1552. A Latin translation made by Gelenius was afterwards added, and printed several times with it. The Paris edition of 1640 in folio was the best for a whole century; which made Cotelerius say, that "Philo was an author that deserved to have a better text and a better version." In 1742, a handsome edition of his work was published at London by Dr Mangey in two volumes folio; which is certainly preferable if it were only for the paper and print, but it is not so good a one as Philo deserves.

Many of our readers may be desirous of further details respecting this celebrated man; we refer such therefore to *Josephus's Antiquities*, *Eusebius's Ecclesiastical History*, *St Jerome's work De Scriptoribus Ecclesiasticis*, *Eubelius's Bib. Græc. Cave's Hist. Liter.* and vol. II. of *Monuments of the Greek Church*.

PHILOETES, an admiral of the Athenian fleet during the Peloponnesian war. He recommended to his countrymen to cut off the right hand of such of

the enemies as were taken, that they might be rendered unfit for service. His plan was adopted by all the ten admirals except one; but their expectations were frustrated, and instead of being conquerors they were totally defeated at Ægyptos by Lyfander, and Philoctes was put to death with the rest of his colleagues.

PHILOCTETES, in fabulous history, the son of Pean, was the faithful companion of Hercules; who at his death obliged him to swear not to discover the place where his ashes were interred, and presented him with his arrows dipped in the Hydra's blood. The Greeks at the siege of Troy being informed by an oracle that they could never take that city without those fatal arrows, went to Philoctetes, and insisted upon his discovering where he had left his friend; when Philoctetes, to evade the guilt of perjury, let them know where Hercules was intombed, by stamping upon the place: but he was punished for the violation of his oath, by dropping an arrow upon that spot; which, after giving him great agony, was at length cured by Macaon. He was afterwards taken by Ulysses to the siege of Troy, where he killed Paris with one of his arrows.

PHILOLAUS, of Crotona, was a celebrated philosopher of antiquity, of the school of Pythagoras, to whom that philosopher's *Golden Verses* have been ascribed. He made the heavens his principal object of contemplation; and has been idly (A) supposed to have been the author of that true system of the world which Copernicus afterwards revived. This made Bullialdus place the name of Philolaus at the head of two works, written to illustrate and confirm that system.

"He was (says Dr Enfield) a disciple of Archytas, and flourished in the time of Plato. It was from him that Plato purchased the written records of the Pythagorean system, contrary to an express oath taken by the society of Pythagoreans, pledging themselves to keep secret the mysteries of their sect. It is probable, that among these books were the writings of Timæus, upon which Plato formed the dialogue which bore his name. Pintarch relates, that Philolaus was one of the persons who escaped from the house which was burned by Cylon, during the life of Pythagoras; but this account cannot be correct. Philolaus was contemporary with Plato, and therefore certainly not with Pythagoras. Interfering in affairs of state, he fell a sacrifice to political jealousy.

"Philolaus treated the doctrine of nature with great subtlety, but at the same time with great obscurity; referring every thing that exists to mathematical principles. He taught, that reason, improved by mathematical learning, is alone capable of judging concerning the nature of things; that the whole world consists of infinite and finite; that number subsists by itself, and is the chain which by its power sustains the eternal frame of things; that the Monad is not the sole principle of all things, but that the Binary is necessary to furnish materials from which all subsequent numbers may be produced; that the world is one whole, which has a fiery centre, about which the ten celestial spheres revolve, heaven, the sun, the planets, the

Philoctetes,
Philolaus.

Hist. of
Philosophy

A) We say idly, because there is undoubted evidence that Pythagoras learned that system in Egypt. See PHILOSOPHY.

Philolaus. the earth, and the moon; that the sun has a vitreous surface, whence the fire diffused through the world is reflected, rendering the mirror from which it is reflected visible; that all things are preserved in harmony by the law of necessity: and that the world is liable to destruction both by fire and by water. From this

summary of the doctrine of Philolaus it appears probable, that, following Timæus, whose writings he professed, he so far departed from the Pythagorean system as to conceive two independent principles in nature, God and Matter, and that it was from the same source that Plato derived his doctrine upon this subject." Philolaus.

P H I L O L O G Y.

¹ **PHILOLOGY** is compounded of the two Greek words φιλος and λογος, and imports "the desire of investigating the properties and affections of words." The sages of Greece were, in the most ancient times, denominated σοφοι, that is, *wise men*. Pythagoras renounced this pompous appellation, and assumed the more humble title of φιλοσοφος, that is, *a lover of wise men*. The learned Greeks were afterwards called *philosophers*; and in process of time, in imitation of this epithet, the word *philologer* was adopted, to import "a man deeply versed in languages, etymology, antiquities, &c." Hence the term *philology*, which denotes the science that we propose briefly to discuss in the following article.

² **Object and uses of philology.** Though philology, in its original import, denoted only the study of words and language, it gradually acquired a much more extensive, and at the same time a much more useful, as well as more exalted, signification. It comprehended the study of grammar, criticism, etymology, the interpretation of ancient authors, antiquities; and, in a word, every thing relating to ancient manners, laws, religion, government, language, &c. In this enlarged sense of the word, philology becomes a science of the greatest utility; opens a wide field of intellectual investigation; and indeed calls for a more intense exertion of industry, and multifarious erudition, than most of those departments of literature which custom hath dignified with more high-sounding names. It is indeed apparent, that, without the aid of philological studies, it is impossible, upon many occasions, to develope the origin of nations; to trace their primary frame and constitution; to discover their manners, customs, laws, religion, government, language, progress in arts and arms; or to learn by what men and what measures the most celebrated states of antiquity rose into grandeur and consideration. The study of history, so eminently useful to the legislator, the divine, the military man, the lawyer, the philosopher, and the private gentleman who wishes to employ his leisure in a manner honourable and improving to himself, and useful to his country, will contribute very little towards enlightening the mind without the aid of philological researches. For these reasons we shall endeavour to explain the various branches of that useful science as fully and as intelligibly as the nature of the present undertaking will permit.

³ **Object of this article.** Most of the branches of philology have been already canvassed under the various heads of CRITICISM, ETYMOLOGY, GRAMMAR, LANGUAGE, &c. There still remains one part, which has been either slightly touched upon, or totally omitted, under the foregoing topics: we mean, the nature and complexion of most of the oriental tongues; as also some of the radical dialects of the languages of the west. As we would willingly

gratify our readers of every description to the utmost of our power, we shall endeavour in this place to communicate to them as much information upon that subject as the extent of our reading, and the limits prescribed one single article, will permit.

Before we enter upon this subject, we must observe, that it is not our intention to fill our pages with a tedious, uninteresting, catalogue of barbarous languages, spoken by savage and inconsiderable tribes, of which little, or perhaps nothing, more is known than barely their names. Such an enumeration would swell the article without communicating one single new idea to the reader's antecedent stock. We shall therefore confine our inquiries to such languages as have been used by considerable states and societies, and which of consequence have acquired a high degree of celebrity in the regions of the east.

What was the antediluvian language, or whether it was divided into a variety of dialects as at this day, can only be determined by the rules of analogy; and these will lead us to believe, that whatever might have been the primitive language of mankind, if human nature was then constituted as it is at present, a great variety of dialects must of necessity have sprung up in the space of near 2000 years. If we adopt the Mosaic account of the antediluvian events, we must admit that the descendants of Cain for some ages lived separated from those of Seth. Their manner of life, their religious ceremonies, their laws, their form of government, were probably different, and these circumstances would of course produce a variety in their language. The posterity of Cain were an inventive race. They found out the art of metallurgy, music, and some think of weaving; and in all probability many other articles conducive to the ease and accommodation of life were the produce of their ingenuity. A people of this character must have paid no small regard to their words and modes of expression. Wherever music is cultivated, language will naturally be improved and refined. When new inventions are introduced, a new race of words and phrases of necessity spring up, corresponding to the recent stock of ideas to be intimated. Besides, among an inventive race of people, new vocables would be continually fabricated, in order to supply the deficiencies of the primitive language, which was probably scanty in words, and its phraseology unpolished. The Cainites, then, among their other improvements, cannot well be supposed to have neglected the cultivation of language.

Many conjectures have been hazarded both by ancient and modern authors with respect to the origin of writing; an art nearly connected with that of speaking. According to Pliny⁴, "the Assyrian letters had all ways existed; some imagined that letters had been invented

⁴ Variety of dialects before the deluge;

⁵ especially among the children of Cain.

⁶ Nat. Hist. lib. vii. vented cap. 56.

History of
6
Origin of
writing.

vented by the Egyptian Mercury; others ascribed the honour of the invention to the Syrians." Some contend, that letters were an antediluvian invention, preserved among the Chaldeans or Assyrians, who were the immediate descendants of Noah, and inhabited those very regions in the neighbourhood of which the ark rested, and where that patriarch afterwards fixed his residence. This circumstance, they think, affords a strong presumption that the use of letters was known before the deluge, and transmitted to the Assyrians and Chaldeans by Noah their progenitor, or at least by their immediate ancestors of his family. Others, with much probability, conclude that letters were of Divine origin, and were first communicated at Sinai.

The descendants of Seth, according to the oriental tradition, were chiefly addicted to agriculture and tending of cattle. They devoted a great part of their time to the exercises of piety and devotion. From this circumstance they came to be distinguished by the title of the (A) *sons of God*. According to this description, the Sethites were a simple (B), unimproved race of people till they mingled with the race of Cain; after which period they at once adopted the improvements and the vices of that wicked family.

It is not, however, probable, that all the descendants of Seth, without exception, mingled with the Cainites. That family of which Noah was descended had not incorporated with the race of Cain: it was, according to the sacred historian, lineally descended from Seth, and had preserved the worship of the true God, when, it is probable, the greatest part of mankind had apostatized and become idolaters (C). Along with the true religion, the progenitors of Noah had preserved that simplicity of manners and equability of character which had distinguished their remote ancestors. Agriculture and rearing cattle had been their favourite occupations. Accordingly we find, that the patriarch Noah, immediately "after the deluge," became a husbandman, and "planted a vineyard." The chosen patriarchs, who doubtless imitated their pious ancestors, were shepherds, and employed in rearing and tending cattle. Indeed there are strong presumptions that the Chaldeans, Assyrians, Syrians, Canaanites, and Arabians, in the earliest ages followed the same profession.

From this deduction, we imagine it is at least probable, that the ancestors of Noah persisted in the observance of the same simplicity of manners which had

been handed down from Adam to Seth, and from him to Enoch, Methuselah, Lamech, and from this last to Noah. According both to scripture and tradition, innovations were the province of the Cainites, while the descendants of Seth adhered to the primitive and truly patriarchal institutions.

If these premises are allowed the merit of probability, we may justly infer that the language of Noah, whatever it was, differed very little from that of Adam (D); and that if it is possible to ascertain the language of the former, that of the latter will of course be discovered. We shall then proceed to throw together a few observations relating to the language of Noah, and leave our readers to judge for themselves. We believe it will be superfluous to suggest, that our intention in the course of this deduction, is, if possible, to trace the origin and antiquity of the Hebrew tongue: and to try to discover whether that language, or any of its sister dialects, may claim the honour of being the original language of mankind.

Whatever may have been the dialect of Noah and his family, that same dialect, according to the Mosaic account, must have obtained, without any alteration, till the era of the building of the tower of Babel.—Upon this occasion a dreadful convulsion took place; the language of mankind was confounded, and men were scattered abroad upon the face of all the earth.

How far this catastrophe (E) extended, is not the business of the present inquiry to determine. One thing is certain beyond all controversy, namely, that the languages of all the nations which settled near the centre of population were but slightly affected by its influence. A very judicious writer has observed*, that 3000 years after, the inhabitants of those countries exhibited a very strong resemblance of cognation, "in their language, manner of living, and the lineaments of their bodies. At the same time he observes, that the resemblance in all those particulars was most remarkable among the inhabitants of Mesopotamia." This observation, with respect to language, will, we doubt not, be vouched by every one of our readers who has acquired even a superficial knowledge of the languages current in those quarters, at a very early period.

It appears, then, that the languages of the Armenians, Syrians, Assyrians, Arabians, and probably of the Chanaanim, did not suffer materially by the confusion of tongues. This observation may, we imagine, be extended to many of the dialects (F) spoken by the people who settled in those countries not far distant

(A) From this passage (Gen. ch. vi. ver. 2) misunderstood, originated the absurd idea of the connection between angels and mortal women. See *Joseph. Antiqu. Jud. l. i. cap. 4.* See *Euseb. Chron. lib. 1.* All the fathers of the church, almost without exception, adopted this foolish notion. See also *Philos. Jud. p. 198. ed. Turn. Paris 1552.*

(B) The orientals, however, affirm that Seth, whom they call *Edris*, was the inventor of astronomy.

(C) We think it highly probable that idolatry was established before the flood; because it prevailed almost immediately after that catastrophe. See POLYTHEISM.

(D) For the first language communicated to Adam, see the article on LANGUAGE: also *Shuckford's Connex.* Vol. I. l. ii. p. 111. *et seq.*

(E) Josephus and the fathers of the church tell us, that the number of languages produced by the confusion of tongues was 72; but this is a mere rabbinical legend.

(F) The languages of the Medes, Persians, Phœnicians, and Egyptians, very much resembled each other in their original complexion; and all had a strong affinity to the Hebrew, Chaldean, Syriac, &c. See *Walton's Præf. 3*

History of flant from the region where the sacred historian has fixed the original seat of mankind after the deluge. The inference then is, that if Noah and his family spoke the original language of Adam, as they most probably did, the judgment which affected the confusion of tongues did not produce any considerable alteration in the language of such of the descendants of Noah as settled near the region where that patriarch had fixed his residence after he quitted the ark.

9
Only a part of mankind engaged in building the tower,
But supposing the changes of language produced by the catastrophe at the building of the tower as considerable as has ever been imagined, it does not, after all, appear certain that all mankind without exception were engaged in this impious project. If this assertion should be well founded, the consequence will be, that there was a chosen race who did not engage in that enterprise. If there was such a family, society, or body of men, it will follow, that this family, society, &c. retained the language of its great ancestor without change or variation. That such a family did actually exist, is highly probable, for the following reasons:

‡ Gen. ix. 25.

1. We think there is reason to believe, that Ham, upon the heavy curse denounced upon him by his father ‡, retired from his brethren, and fixed his residence elsewhere. Accordingly, we find his descendants scattered far and wide, at a very great distance from the Gordycean mountains, where the ark is generally supposed to have rested immediately after the flood. Some of them we find in Chaldea, others in Arabia Felix, others in Ethiopia (G), others in Canaan, and others in Egypt; and, finally, multitudes scattered over all the coast of Africa. Between those countries were planted many colonies of Shemites, in Elam, Assyria, Syria, Arabia, &c. We find, at the same time, the descendants of Shem and Japheth settled, in a great degree, contiguous to each other. This dispersion of the Hamites, irregular as it is, can scarce, we think, have been accidental; it must have been owing to some uncommon cause, and none seems more probable than that assigned above. If, then, the descendants of Ham separated early, and took different routs, as from their posterior situations it appears they did, they could not all be present at the building of the tower.

10
and those not the descendants of Shem.

‡ Chap. x. verse 22.

2. It is not probable that the descendants of Shem were engaged in this undertaking, since we find that they were not scattered abroad upon the face of all the earth. The children of Shem were || Elam, Ashur, Arphaxad, Lud, and Aram. Elam settled near the mouth of the river Tigris, in the country which, by

Gentile writers, was called *Tlymais*. Above him, on the same river, lay the demefie of Ashur on the western side. In like manner, upon the same river, above him was situated Aram, who possessed the country of Aramien; and opposite to him was Arphaxad, or Arbaces or Arbaches, and his country was denominated *Arphachitis*. Lud, as some think, settled in Lydia, among the sons of Japhet; but this opinion seems to be without foundation (H). Here, then, there is dispersion, but such as must have originated from the nature of the thing. The four, or rather the five, brothers, all settled contiguous, without being scattered abroad upon the face of the whole earth. Besides, there was no confusion of language among these tribes: they continued to use one and the same *lip* through many succeeding generations.

Language.

From these circumstances, it appears that the posterity of Shem were not involved in the guilt of the builders of the tower, and of consequence did not undergo their punishment. If, then, the language of the Shemites was not confounded upon the erection of the tower, the presumption is, that they retained the language of Noah, which, in all probability, was that of Adam. Some dialectical differences would in process of time creep in, but the radical fabric of the Language would remain unaltered.

11
The language of Adam preserved in the family of Shem.

3. The posterity of Shem appear in general to have cultivated the pastoral life. They imitated the style of living adopted by the antediluvian posterity of *Seth*. No sooner had Noah descended from the ark, than he became *Ish ba Alamah*, a man of the earth; that is, a husbandman, and planted a vineyard. We find that some ages after, Laban the Syrian had flocks and herds; and that the chief wealth of the patriarch Abraham and his children consisted in their flocks and herds. Even his Gentile descendants, the Ishmaelites and Midianites, seem to have followed the same occupation. But people of this profession are seldom given to changes: their wants are few, and of consequence they are under few or no temptations to deviate from the beaten track. This circumstance renders it probable, that the language of Noah, the same with that of Adam, was preserved with little variation among the descendants of Arphaxad down to Abraham.

12
down to Abraham.

We have observed above, that Ham upon the curse denounced against him by his father, very probably left the society of his other brothers, and emigrated elsewhere, as Cain had done in the antediluvian world. There is a tradition still current in the East, and which was adopted by many of the Christian fathers (1), that Noah, in the 930th year of his life, by divine appointment,

Proleg.; Gale's *Court of the Gent.* vol. 1. l. 1. ch. 11. page 70. *et seq.*; Boch. *Phaleg* and *Canaan* *pass.* To these we may add the Greek language, as will appear more fully below.

(G) Josephus informs us, that all the nations of Asia called the Ethiopians *Cushim*, l. 1. cap. 7.

(H) The ancient name of Lydia was *Mæonia*. See Strabo *Casaub.* l. 13. page 586. chap. 7. *Rhod.* 577. The Lydians were celebrated for inventing games; on which account they were nicknamed by the Æolian Greeks *παιδοι*, *Lydi* or *Ludi*, from the Hebrew words *lutz*, *lulere*, *illudere*, *deridere*. We find (Ezek. chap. xvii. ver. 10.) the men of Elam and the men of Lud joined in the defence of Tyre: which seems to intimate, that the Elamites and Ludim were neighbours. If this was actually the case, then Lud settled in the same quarter with his brothers.

(1) *Epiph.* vol. i. page. 5. *ibid.* pag. 709. where our learned readers will observe some palpable errors above. *Rhinocorura*, &c. Euseb. *Chron.* pag. 10. Syncellus, pag. 89. Cedrenus, *Chron. Pasch.* &c.

ment, did, in the most formal manner, divide the whole terraqueous globe among his three sons, obliging them to take an oath that they would stand by the decision. Upon this happened a migration at the birth of Peleg, that is, about three centuries after the flood. It is affirmed, that Nimrod the arch-rebel disregarded this partition, and encroached upon the territory of Ashur, which occasioned the first war after the flood.

The Greeks had acquired some idea of this partition, which they supposed to have been between Jupiter, Neptune, and Pluto. Plato seems to have heard of it (κ): "For (says he) the gods of old obtained the dominion of the whole earth, according to their different allotments. This was effected without any contention, for they took possession of their several provinces in a fair and amicable way, by lot."

Josephus, in his account of the dispersion of mankind, plainly intimates a divine destination; and Philo Judæus (ι) was of the same opinion before him.

In consequence of this arrangement, the sons of Shem possessed themselves of the countries mentioned in the preceding pages: the posterity of Japhet had spread themselves towards the north and west; but the Hamites, who had separated from their brethren in consequence of the curse, not choosing to retire to their quarters, which were indeed very distant from the place where the ark rested, seized upon the land of Canaan (m). Perhaps, too, it might be suggested by some malicious spirits, that the aged patriarch was dealing partially, when he assigned Ham and his posterity a quarter of the world to inhabit not only remote from the centre of population, but likewise sequestered from the rest of mankind (n).

Be that as it may, the children of Ham removed eastward, and at length descending from the Carduchean or Gordyean mountains, directed their course westward, and arrived at the plains of Shinar, which had been possessed by the Athurim ever since the era of the first migration at the birth of Peleg. The sacred historian informs us, that the whole earth "was of one language and of one speech;" that in journeying from the east, they lighted upon the plain of Shinar, and dwelt there. In this passage we find no particular people specified; but as we find Nimrod,

one of the descendants of Ham, settled in that country, we are sure that they were the offspring of that patriarch. It would not, we think, be easy to assign a reason how one branch of the family of Ham came to plant itself in the midst of the sons of Shem by any other means but by violence.

It is indeed generally supposed, that Nimrod, at the head of a body of the children of Ham, made war upon Ashur, and drove him out of the country of Shinar; and there laid the foundation of that kingdom, the beginning of which was Babel: that this chief, supported by all the Cushites, and a great number of apostates from the family of Shem and Japhet who had joined him, refused to submit to the divine ordinance by the mouth of Noah, with respect to the partition of the earth; and that he and his adherents were the people who erected the celebrated tower, in consequence of a resolution which they had formed to keep together, without repairing to the quarters assigned them by the determination of heaven. This was the crime which brought down the judgment of the Almighty upon them, by which they were scattered abroad upon the face of all the earth. The main body of the children of Shem and Japhet were not engaged in this impious undertaking; their language, therefore, was not confounded, nor were they themselves scattered abroad. Their habitations were contiguous; those of the Shemites towards the centre of Asia; the dwellings of Japhet were extended towards the north and north-west; and the languages of both these families continued for many ages without the least variation, except what time, climate, laws, religion, new inventions, arts, sciences, and commerce, &c. will produce in every tongue in a succession of years.

The general opinion then was, that none but the progeny of Ham and their associates were present at the building of the tower, and that they only suffered by the judgment (o) consequent upon that attempt. There are even among the Pagans some allusions to the division of the world among the three sons of Noah. Many of the learned have imagined that this patriarch was Saturn; and that his three sons were Jupiter, Neptune, and Pluto, as has been observed above.

Bero-

(κ) Critias, vol. 3. pag. 109. *Serr.* Apollodorus mentions a time when the gods respectively selected particular cities and regions, which they were to take under their peculiar protection.

(λ) L. 10. p. 236. Turn. Paris 1552. We have a plain allusion to this distribution (Deut. ch. xxvii. ver. 7.) "When the most High divided to the nations their inheritance, when he separated the sons of Adam, he set the bounds of the people, according to the number of the children of Israel; for the Lord's portion is his people; Jacob is the lot of his inheritance." From this passage it appears, that the whole was arranged by the appointment of God, and that the land of Canaan was expressly reserved for the children of Israel. St Paul, Acts ch. xvii. ver. 26. speaks of this divine arrangement, "God made of one blood all nations of men, for to dwell on all the face of the earth; and determined the bounds of their habitation."

(m) the ark, according to the most probable accounts, rested upon mount Ararat in Armenia.

(n) We think it is by no means improbable that Noah, well knowing the wickedness of the family of Ham, and especially their inclination to the idolatry of the antediluvians, might actually intend to separate them from the rest of mankind.

(o) Some learned men have imagined that this confusion of language, which the Hebrew calls of *Lip*, was only a temporary failure of pronunciation, which was afterwards removed. This they are led to conclude, from the agreement of the languages of these people in after times.

13
The tower
of Babel
built by
the children
of Ham.

History of
• Euseb.
Chron.

Berosus*, in his history of the Babylonians, informs us, that Noah, at the foot of Mount Baris or Luban, where the ark rested, gave his children their last instructions, and then vanished out of sight. It is now generally believed that the Xithrusus of Berosus was Noah. Eupolemus†, another Heathen writer, tells us, “that the city Babel was first founded, and afterwards the celebrated tower; both which were built by some of those people who escaped the deluge. They were the same with those who in after times were exhibited under the name of *giants*. The tower was at length ruined by the hand of the Almighty, and those giants were scattered over the whole earth.” This quotation plainly intimates, that according to the opinion of the author, only the rascally mob of the Hamites, and their apostate associates, were engaged in this daring enterprize.

† Euseb.
Prep. Ev.
lib. 9.

Indeed it can never be supposed that Shem, if he was alive at that period, as he certainly was, would co-operate in such an absurd and impious undertaking. That devout patriarch, we think, would rather employ his influence and authority to divert his descendants from an attempt which he knew was undertaken in contradiction to an express ordinance of Heaven; and it is surely very little probable that Elam, Ashur, Arphaxad, and Aram, would join that impious confederacy, in opposition to the remonstrances of their father.

The building of the tower, according to the most probable chronology, was undertaken at a period so late, that *all mankind* could not possibly have concurred in the enterprize.

Many of the fathers were of opinion, that Noah settled in Armenia, the country where the ark rested; and that his descendants did not leave that region for five generations ‡, during the space of 659 years. By this period the human race must have been so amazingly multiplied, that the plains of Shinar could not have contained them. According to the Samaritan Pentateuch, and the Septuagint version, Peleg was born in the 134th year of his father Eber. Even admitting the vulgar opinion, that the tower was begun to be built, and the dispersion consequent upon that event to have taken place at this era, the human race would have been by much too numerous to have universally concurred in one sign.

‡ Epiph.
Hæres.
lib. 1.

From these circumstances, we hope it appears that the whole mass of mankind was not engaged in building the tower; that the language of all the human race was not confounded upon that occasion; and that the dispersion reached only to a combination of Hamites, and of the most profligate part of the two other families, who had joined their wicked confederacy.

VOL. XIV.

We have pursued this argument to considerable length, because some have inferred, from the difference in languages existing at this day, that mankind cannot have sprung from two individuals; because, from the connection still existing among languages, some have been bold enough to question the fact, though plainly recorded in sacred history; and lastly, because we imagine that some of our readers, who do not pretend to peruse the writings of the learned, may be gratified by seeing the various opinions respecting the confusion of tongues, and the dispersion of mankind, collected into one mass, equally brief, we hope, and intelligible: and this view of these opinions, with the foundations on which they respectively rest, we think may suffice to prove, that the language of Noah was for some ages preserved unmixed among the descendants of both Shem and Japhet.

Language.
The difference
in the
two families.

To gratify still farther such of our curious readers as may not have access to more ample information, we shall in this place exhibit a brief detail of the circumstances which attended this fatal attempt. The people engaged in it have been held up as a profligate race. The Almighty himself denominates them “*the children of men*,” which is the very appellation by which the antediluvian sinners were characterized; *the sons of God saw the daughters of men*, &c. Their design in raising this edifice was “*to make them a name, and to prevent their being scattered abroad upon the face of the whole earth*.”

Whatever resolution the rest of mankind might take, they had determined to maintain themselves on that spot. The tower was intended as a centre of union, and perhaps as a fortress of defence. Such a stupendous fabric, they imagined, would immortalize their memory, and transmit the name of their confederacy with éclat (r) to future ages. This design plainly intimates, that there was only a party concerned in the undertaking, since, had all mankind been engaged in it, the purpose would have been foolish and futile. Again, they intended, by making themselves a name, to prevent their being scattered abroad upon the face of the earth. This was an act of rebellion in direct contradiction to the divine appointment, which constituted their crime, and brought down the judgment of Heaven upon their guilty heads. The consequence of the confusion of languages was, that the projectors left off to build (q), and were actually scattered abroad, contrary to their intention.

* Gen.
chap. ix.

Abydenus, in his Assyrian annals, records, that the tower was carried up to heaven; but that the gods ruined it by storms and whirlwinds, and ever threw it upon the heads of those who were employed in the work, and that the ruins of it were called *Babel*.

15
Pagan tradition concerning the tower of Babel.

3 Q

Babel,

(r) Many foolish and absurd notions have been entertained concerning this structure. Some have imagined that they meant to take shelter there in case of a second deluge; others, that it was intended for idolatrous purposes; others, that it was to be employed as an observatory. Its dimensions have likewise been most extravagantly magnified. Indeed Strabo, l. 16. mentions a tower of immense size remaining at Babylon in his time, the dimensions of which were a stadium every way. This, however, seems to have been the remains of the temple of Bel or Belus.

(q) For a description of the tower, see the article BABEL.

(r) See the Greek original of this quotation, Euseb. Chron. lib. 1. page 13.

History of *byz.* Before this there was but one language subsisting among men: but now there arose *ταυτηγεννησιν, a manifold speech*; and he adds, that a war soon after broke out between (s) Titan and Cronus." (r) The Sybilline oracles give much the same account of this early and important transaction.

* Philip. 1b. 13. 1: 3. "Justin † informs us, that the Phœnicians who built Tyre were driven from Assyria by an earthquake. These Phœnicians were the descendants of Mizraim the youngest son of Ham; and were, we think, confederates in building the tower, and were driven away by the catastrophe that ensued. Many other allusions to the dispersion of this branch of the family occur in Pagan authors, which the limits to be observed in an inquiry of this nature oblige us to omit. Upon the whole, we think it probable that the country of Shinar lay desolate for some time after this revolution; for the dread of the judgment inflicted upon the original inhabitants would deter men from settling in that insipid region. At last, however, a new colony arrived, and Babel, or Babylon, became the capital of a flourishing kingdom.

Our readers, we believe, will expect that we should say something of Nimrod the mighty hunter, who is generally thought to have been deeply concerned in the transactions of this period. According to most authors, both ancient and modern, this patriarch was the leader of the confederates who erected the tower, and the chief instigator to that enterprize. But if the tower was built at the birth of Pheleg, according to the Hebrew computation, that chief was † either a child, or rather not born at that period (v). The Seventy have pronounced him a giant, as well as a huntsman. They have translated the Hebrew word *gibur*, which generally signifies *strong, mighty*, by the word *γίγας; giant*; an idea which we imagine those translators borrowed from the Greeks. The antediluvian giants are called *Nephelim* and *Rephaim*, but never *Gelurim*. The Rabbinical writers, who justly hated the Babylonians, readily adopted this idea (x); and the fathers of the church, and the Byzantine historians, have universally followed them. He has been called *Nimrod, Nembrod, Nymbrod, Nembros, and Nembri*. Not a few have made him the first *Bacchus*, and compounded his name of *Bar*, a son, and *Cush*, that is, the son of *Cush*. Some have imagined that he was the Orion of the Pagans, whose shade is so nobly described by Homer ‡. But the etymology of this last name implies something (y) honourable, and very unsuitable to the idea of the tyrant *Nimrod*. It must be observed, however,

that we find nothing in Scripture to warrant the supposition of his having been a tyrant; so far from it, that (z) some have deemed him a benefactor to mankind. See *Nimrod*.

The beginning of this prince's kingdom was Babel. Eusebius gives us first † a catalogue of six kings of the Chaldeans, and then another of five kings of Arabian extraction, who reigned in Chaldea after them. This might naturally enough happen, since it appears that the inhabitants of those parts of Arabia which are adjacent to Chaldea were actually Cushites, of the † same family with the Babylonians.

The Cushites, however, were at last subdued, perhaps partly expelled Chaldea by the *Chafidim*, who probably claimed that territory as the patrimony of their progenitors. That the *Chafidim* were neither *Cushites*, nor indeed *Hamites*, is obvious from the name. The Hebrews, and indeed all the Orientals ‡, denominated both the people who inhabited the eastern coast of Arabia *Cushim*, and also the Ethiopians who sprung from the last mentioned people. Had the later inhabitants of Chaldea been the descendants of Cush, the Jewish writers would have called them *Cushim*. We find they called the Phœnicians *Chanaanim*, the Syrians *Aramim*, the Egyptians *Mizraim*, the Greeks *Jonim*, &c. The *Chafidim*, therefore, or modern inhabitants of Chaldea, were positively descended of one *Chesed* or *Chafed*; but who this family-chief was, it is not easy to determine. The only person of that name whom we meet with in early times is the fourth son of Nahor §, the brother of Abraham; and some have been of opinion that the Chaldeans were the progeny of this same *Chesed*. This appears to us highly probable, because both *Abram* and *Nahor* were natives of *Ur* of the *Chafidim*. The former, we know, in consequence of the divine command, removed to *Haran*, afterwards *Charra*; but the latter remained in *Ur*, where his family multiplied, and, in process of time, became masters of the country which they called the land of the *Chafidim*. from *Chesed* or *Chafid*, the name of their ancestor. This account is the more probable, as we find the other branches of Nahor's family settled in the same neighbourhood (A).

How the Greeks came to denominate these people *Chaldæi*, is a question rather difficult to be resolved; but we know that they always affected to distinguish people and places by names derived from their own language. They knew a rugged, erratic nation (B) on the banks of the river *Thermodon*, in the territory of Pontus, bordering on Armenia the *Lefs*.

(s) This war was probably carried on between the leaders of the Hamites and Assur upon their invasion.

(r) Theoph. ad Antol. l. 2. page 107. ed. Paris 1636.

Origin of the name Chaldæ.

History of Lefs. These, in ancient times, were called *Alybes*, or *Chalybes*, because they were much employed in forging and polishing iron. Their neighbours, at length, gave them the name of *Chald* or *Cald*, which imports, in the Armenian dialect, *ferce, hardy, robust*. This title the Greeks adopted, and out of it formed the word *Χαλδαῖοι* "Chaldeans."

The Mosaic history informs us (c), that Ashur went out of *that land* (Shinar) and built Nineveh and several other considerable cities. One of the successors of Ashur was the celebrated Ninus, who first broke the peace of the world*, made war upon his neighbours, and obliged them by force of arms to become his subjects, and pay tribute. Some authors make him the immediate successor of Ashur, and the builder of Nineveh. This we think is not probable; Eusebius, as we have observed above, gives a list of six Arabian princes who reigned in Babylon. These we take to have been the immediate successors of Nimrod, called *Arabians*; because these people were Cushites. Ninus might be reputed the first king of the Assyrians, because he figured beyond his predecessors; and he might pass for the builder of Nineveh, because he greatly enlarged and beautified that city. We therefore imagine, that Ninus was the fifth or sixth in succession after Ashur.

† Lib. 2. Ninus, according to Diodorus Siculus †, made an alliance with Ariæus king of the Arabians, and conquered the Babylonians. This event, in our opinion, put an end to the empire of the Hamites or Cushim in Shinar or Babylonia. The author observes, that the Babylon which figured afterwards did not then exist.

‡ Ch. xxiii. This fact is confirmed by the prophet Isaiah ‡: "Behold the land of the Chasidim; this people was not till Ashur founded it for them that dwell in the wilderness. They set up the towers thereof, &c." After Babylonia was subdued by the Assyrians under Ninus, the capital was either destroyed by that conqueror or deserted by the inhabitants. At length it was re-edified by some one or other of the Assyrian monarchs, who collected the roving Chasidim, and obliged them to settle in the new city. These were subject to the Assyrian empire till the reign of Sardanapalus, when both the Medes and Babylonians rebelled against that effeminate prince.

The Chasidim were celebrated by all antiquity for their proficiency in astronomy, astrology, magic, and curious sciences. Ur or Orchoe (D) was a kind of university for those branches of learning. Such was their reputation in those studies, that over a great part of Asia and Europe a Chaldean and an astrologer were synonymous terms. These sciences, according to the tradition of the Orientals, had been invented by Seth, whom they call *Eshis*; and had been cultivated by his descendants downward to Noah, by whom they were transmitted to Shem, who conveyed them to Arphaxad and his posterity.

To us it appears probable, that the religious sentiments transmitted from Noah through the line of Shem, were kept alive in the family of Arphaxad, and handed down to the families of Serug, Nahor, Terah, Abram, Nahor II. and Haran, &c. The Jewish Rabbins, and all the Persian and Mahomedan writers, make Abraham contemporary with Nimrod; who, say they, persecuted him most cruelly for adhering to the true religion. That these two patriarchs were contemporary, is very improbable, since Nimrod was the third generation after Noah, and Abram the tenth. Abram has been invellied by the rabbinical writers with every department of learning. According to them, he transported from Charæ into Canaan and Egypt, astronomy, astrology, mathematics, geography, magic, alphabetical writing, &c. &c.

After the Babylonish captivity, when the Jews were dispersed over all the east, and began to make *proselytes* of the *gente* among the Pagans, wonderful things were reported of Abram with respect to his attainments in human erudition, as well as his supereminence in virtue and piety. These legendary tales were believed by the proselytes, and by them retailed to their connections and acquaintances. But certainly the holy man either was not deeply versed in human sciences, or did not deem them of importance enough to be communicated to his posterity; since the Jews are, on all hands, acknowledged to have made little progress in these improvements. To think of raising the fame of Abraham, by clasing him with the philosophers, betrays an extreme defect in judgment. He is intitled to praise of a higher kind; for he excelled in piety, was the father of the faithful, the root of the Mes-

3 Q 2

shah,

manufacturing iron, so were they celebrated for making the choicest pieces of armour. They excelled in making *χαλκουργιαι*, or coats of mail, or brigantines used by the bravest of the Persian horsemen. Bochart Pl. Aug. l. 3. cap. 12 and 13, has proved that the word *Chalibha* signifies "scales of brass or steel." From the word *Chaliba*, the Greeks formed their *Χαλκιδες*, *Chalybes*. Xenoph. Cyrop. l. 3. page 43. Steph. represents the Chaldeans, who inhabited a mountainous country bordering upon Armenia, as a very fierce warlike people. Ib. page 127. we have an example of their rapacious character. Id. ib. l. 4. page 192. Hen. Steph. we have an account of their bravery and of their arms. Another instance of their rapacity occurs in their plundering the cattle of Job.

(c) A dispute has arisen about the sense of verse x. chap. 10. Out of that land went forth Ashur, and builded Nineveh. Some approve our translation, which we think is just; others, considering that the inspired writer had been just speaking of Nimrod and the beginning of his kingdom, are of opinion that it should be translated, And out of this land *He* (that is Nimrod) went into Ashur and builded Nineveh. This they make a military expedition, and a violent irruption into the territory of Ashur.

(D) Ur or Orchoe was situated between Nisibis and Corduena. See Ammianus Marcell. Expeditio Juliana, l. 15. It lay not far from the river Tigris. Strabo, l. 16 page 739, tells us that the Chaldean philosophers were divided into different sects, the Orcheni, and Borsippeni, and several others. Diod. Sicul. likewise, lib. ii. page 82. Steph. gives an exact detail of the functions, profession, and establishment of the Chaldeans, to which we must refer our curious readers.

History of fish, and the friend of God. Before these, all other titles vanish away. Such of our readers, however, as have leisure enough, and at the same time learning enough to enable them to consult the rabbinical legends, will be furnished with a full and ample detail of his imaginary exploits and adventures. Others, who are either not willing or not qualified to peruse the writings of the rabbins, may consult Dr Hyde* de Relig. vet. Pers. and the authors of the Universal History †, where they will find materials sufficient to gratify their curiosity. We shall only observe, in addition to what we have already said, that the Persians, Chaldeans, and Arabians, pretended that their religion was that of Abraham; that honourable mention is made of him in the Koran; and that the name of Abraham or Ibrahim was celebrated over all the east. See ABRAHAM.

* Chap. ii.
† Vol. I.

In the progress of this dissertation, we have seen that the language of Noah was, in all probability, the same or nearly the same with that of Adam. Additions and improvements might be introduced, but still the radical stamina of the language remained unchanged. It has likewise, we hope, appeared, that the confusion of language at the building of the tower of Babel was only partial, and affected none but the rebellious crew of the race of Ham and the apostate part of the families of Shem and Japhet. We have concluded, that the main body of the race of Shem, at least, were neither dispersed nor their language confounded; and that consequently the descendants of that patriarch continued to speak their paternal dialect or the uncorrupted language of Noah. To these arguments we may add the liberty to add another, which is, that in all probability the worship of the true God was preserved in the line of Arphaxad, after the generality of the other parts had lapsed into idolatry. Out of this family Abraham was taken, in whose line the true religion was to be preserved. Whether Abraham was an idolater when he dwelt in Chaldea, the scripture does not inform us, though it seems to be evident that his father was. One thing, however, is certain, namely, that Jehovah (E) appeared to him, and pronounced a blessing upon him before he left Ur of the Chaldees. This circumstance no doubt indicates, that this patriarch had made uncommon advances in piety and virtue, even prior to his emigration. The progenitors of his family had been distinguished by adhering to the true religion. About this time, however, they began to degenerate, and to adopt the zebulim of their apostate neighbours. It was then that Abraham was commanded by Heaven to "leave his kindred and his father's house, and to travel into a land which was to be shown him." The Almighty intended that the true religion should be preserved in his line, and therefore removed him from a country and kindred, by the influence of whose bad example his religious principles might be endangered. His family had only of late apostatized; till that period they had preserved both the language and religion of their venerable ancestors.

But however much Abraham might differ from the other branches of his family in his religious sentiments,

his language was certainly in unison with theirs. The consequence of this unquestionable position is, that the language which he carried with him into Canaan was exactly the same with that of his family which he relinquished when he began his peregrinations. But if this be true, it will follow, that the language afterwards denominated Hebrew, and that of the Chaldeans or Chaldeans were originally one and the same. This, we think, will not be controverted. There is then an end of the dispute concerning the original language of mankind. We have advanced some presumptive proofs in the preceding pages, that the language of Adam was transmitted to Noah, and that the dialect of the latter was preserved in the line of Arphaxad downwards to the family of Abraham: and it now appears that the Hebrew and Chaldean were originally spoken by the same family, and of course were the same between themselves, and were actually the first language upon earth, according to the Mosaic history. Numberless additions, alterations, improvements, we acknowledge, were introduced in the course of 2000 years; but still the original stamina of the language were unchanged. Our readers will please to observe, that the Orientals are not a people *given to change*; and that this character, in the earliest ages, was still more prevalent than the present. This assertion, we presume, needs no proof.

In confirmation of these presumptive arguments, we may add the popular one which is commonly urged upon this occasion, viz. that the names of antediluvian persons and places mentioned by the sacred historian, are generally of Hebrew original, and significant in that language. Some of them, we acknowledge, are not so; but in this case it ought to be remembered, that a very small part of that language now exists, and that probably the radicals from which these words are descended are among the number of those which have long been lost.

SECT. I. *The Hebrew Language.*

HAVING thus proved the priority of the Hebrew to every other language that has been spoken by men, we shall now proceed to consider its nature and genius; from which it will appear still more evidently to be an original language, neither improved nor debased by foreign idioms. The words of which it is composed are short, and admit of very little flexion. The names of places are descriptive of their nature, situation, accidental circumstances, &c. Its compounds are few, and inartificially joined together. In it we find few of those artificial affixes which distinguish the other cognate dialects; such as the Chaldean, Syrian Arabian, Phœnician, &c. We find in it no traces of improvement from the age of Moses to the era of the Babylonish captivity. The age of David and Solomon was the golden period of the Hebrew tongue: and yet, in our opinion, it would puzzle a critic of the nicest acumen to discover much improvement even during that happy era. In fact, the Jews were by no means an inventive people. We hear nothing of their progress in literary pursuits; nor do they seem to have

12
Character-
istics of the
Hebrew
language.

Hebrew
Language.

been industrious in borrowing from their neighbours. The laws and statutes communicated by Moses were the principal objects of their studies. These they were commanded to contemplate day and night; and in them they were to place their chief delight. The consequence of this command was, that little or no regard could be paid to taste, or any other subject of philosophical investigation. Every unimproved language abounds in figurative expressions borrowed from sensible objects. This is in a peculiar manner the characteristic of the language in question; of which it would be superfluous to produce instances, as the fact must be obvious even to the attentive reader of the English Bible.

In the course of this argument, we think it ought to be observed, and we deem it an observation of the greatest importance, that if we compare the other languages which have claimed the prize of originality from the Hebrew with that dialect, we shall quickly be convinced that the latter has a just title to the preference. The writers who have treated this subject, generally bring into competition the Hebrew, Chaldean, Syrian, and Arabian. Some one or other of these has commonly been thought the original language of mankind. The arguments for the Syrian and Arabian are altogether futile. The numerous improvements superinduced upon these languages, evidently prove that they could not have been the original language. In all cognate dialects, etymologists hold it as a maxim, that the least improved is likely to be the most ancient.

We have observed above, that the language of Abraham and that of the Chædæim or Chaldeans were originally the same; and we are persuaded, that if an able critic should take the pains to examine strictly these two languages, and to take from each what may reasonably be supposed to have been improvements or additions since the age of Abraham, he will find intrinsic evidence sufficient to convince him of the truth of this position. There appear still in the Chaldean tongue great numbers of (r) words the same with the Hebrew, perhaps as many as mankind had occasion for in the most early ages; and much greater numbers would probably be found if both languages had come down to us entire. The construction of the two languages is indeed somewhat different; but this difference arises chiefly from the superior improvement of the Chaldean. While the Hebrew language was in a manner stationary, the Chaldean underwent progressive improvements; was enlivened by antitheses, rendered sonorous by the disposition of vocal sounds, acquired a copiousness by compounds, and a majesty by affixes and prefixes, &c. In process of time, however, the difference became so great, that the Israelites did not understand the Chaldean language at the era of the

20

dean.

Babylonish captivity. This much the prophet* intimates, when he promises the pious Jews protection from a fierce people; a people of a deeper speech than they could perceive; of a flaming tongue, that they could not understand.^{Hebrew Language. Isa. xl. ver. 17.}

The priority of the Chaldean tongue is indeed contended for by very learned writers. Cambesius calls it the mother of all languages; and most of the fathers were of the same opinion. Amiraus has made a collection of argument, not inconsiderable, in favour of it; and Myricæus, after him, did the same. Erpegius, in his Oration for the Hebrew tongue, thought the argument for it and the Chaldean so equal, that he did not choose to take upon him to determine the question.^{Brit. Prof. ad Gram. Syr. Prof. ad Gram. Chald. Oratio de lingua Heb. xii.}

Many circumstances, however, concur to make us assign the propriety to the Hebrew, or rather to make us believe that it has suffered fewest of those changes to which every living tongue is more or less liable. If we strip this language of every thing obviously adventitious, we shall find it extremely simple and primitive.

1. Every thing metaphorical, supposing the vowels and points (e) essential, was certainly unknown in its original character. 2. All the prefixed and affixed letters were added time after time, to give more compass and precision to the language. 3. The various voices, moods, tenses, numbers, and persons of verbs, were posterior improvements; for in that tongue, nothing at first appeared but the indeclinable radix. 4. In the same manner, the few adjectives that occur in the language, and the numbers and regimen of nouns, were not from the beginning. 5. Most of the Hebrew nouns are derived from verbs; indeed many of them are written with the very same letters. This rule is very general; for few verbs are derived from nouns, and none from prepositions. 6. All the verbs of that language, at least all that originally belonged to it, uniformly consist of three letters, and seem to have been at first pronounced as disyllables. If we anatomize the Hebrew language in this manner, we shall reduce it to very great simplicity; we shall confine it to a few names, of things, persons, and actions; we shall make many of its words monosyllables, and give it the true characters of an original language. If at the same time we reflect on the small number of (u) radical words in that dialect, we shall be more and more convinced of its originality.

21
Reasons for
maintain-
ing the
priority of
the He-
brew.

It will not be expected that we should enter into a minute discussion of the grammatical peculiarities of this ancient language. For these we must refer our readers to the numerous and elaborate grammars of that tongue, which are every where easily to be found. We shall only make a few strictures, which naturally present themselves, before we dismiss the subject.

The generality of writers who have maintained the superior

(r) Most of the Chaldean names mentioned in Scripture are pure Hebrew words compounded; such as *N. buchadnezzar, Nabuzaradan, Rabshakeh, Rabmag, Belsazzar, Rabfaris, Nalar, Malabbe, Porsat or Phara, Barofus, Carchemish, Ur, Cutba, Heb. Cusb, &c.* All these words, and a multitude of others which we could mention, approach so near the Hebrew dialect, that their original is discernible at first sight. Most of these are compounds, which the limits prescribed will not allow us to decompose and explain.

(e) The utility of these points will be proved in the following part of this section.

(u) The radical words in the Hebrew language, as it now stands, are about 5000.

Hebrew Language. 22 All Languages in the East originally the same.

superior antiquity of the Hebrew language, have at the same time contended that all other languages of Asia, and most of those of Europe, have been derived from that tongue as their source and matrix. We, for our part, are of opinion, that perhaps all the languages in the eastern part of the globe are derived from it, and were originally one and the same; and that the differences which afterwards distinguished them sprung from climate, caprice, inventions, religion, commerce, conquests, and other accidental causes, which will occur to our intelligent readers. We have endeavoured to prove, in the preceding pages, that all mankind were not concerned in the building of the fatal tower, nor affected by the punishment consequent upon that attempt; and we now add, that even that punishment was only temporary; since we find, that those very Hamites or Cushim, who are allowed to have been affected by it, did certainly afterwards recover the former organization of their *lips*, and differed not more from the original standard than the descendants of Japhet and Shem.

The Jewish rabbis have pretended to ascertain the number of languages generated by the vengeance of Heaven at the building of Babel. They tell us that mankind was divided into 70 nations and 70 languages, and that each of these nations had its tutelary or guardian angel. This fabulous legend is founded on the number of the progeny of Jacob at the time when that patriarch and his family went down into Egypt. Others attribute its origin to the number of the sons and grandsons of Noah, who are enumerated Gen. chap. x.

The fathers* of the church make the languages at the confusion to amount to 72: which number they complete by adding Cushan and Elishah, according to the Septuagint, who are not mentioned in the Hebrew text. This opinion, they think, is supported by the words of Moses, when he saith, that † “when the Most High divided to the nations their inheritance, when he separated the sons of Adam, he set the bounds of the people according to the number of the tribes of Israel.” That is, say they, he divided them into 72 nations, which was the number of the children of Israel when they came into Egypt. The Targum of Ben-Uzzel plainly favours this interpretation; but the Jerusalem Targum intimates that the number of nations were only 12, according to the number of the tribes of Israel. This passage, however, seems to refer to the tribes of the Chanaanim: and imports, that the Almighty assigned to the different sects of that family such a tract of land as he knew would make a sufficient maintenance for the children of Israel ‡. Others have increased the different languages of the dispersion to 120; but the general opinion has fixed them to 70 or 72. Our readers need scarce be put in mind that these opinions are futile and absurd; neither founded in Scripture, profane history, or common sense. At the same time, it shall not be omitted, that, according to Herodotus, the Egyptians held, that the world was divided into 72 habitable regions: and that, in consequence of this tradition, they made

the cynocephalus the emblem of the world, because that in the space of 72 days that animal pines away and dies.

Hebrew Language. 23 Origin of the name Hebrew.

It has been made a question, whether the Hebrew language was denominated from Heber the progenitor of Abraham, or from a word which in that tongue imports *ever, beyond*. Most of the Christian fathers, prior to St Origen, believed that both the Gentile name *Hebrew*, and the name of the language, were derived from the name of the patriarch; but that learned man imagined, that Abraham was called the *Hebrew*, not because he was a descendant of Heber, but because he was a transfluvianus, or from beyond the river Euphrates. The learned Bochart* has strained hard to prove the former position; but to us his arguments do not appear decisive. We are rather inclined to believe, that Abraham was called *Chibri*, (Hebrew), from the situation of the country from which he emigrated when he came to the country of Chanaan; and that in process of time that word became a Gentile appellation, and was afterwards applied to his posterity (1) often by way of reproach, much in the same manner as we say a *Norlander*, a *Norman*, a *Transatlantic*, &c.

* Phaleg, lib. 1. c. 15.

Here we may be indulged an observation, namely, that Abraham, a Hebrew, lived among the Chaldeans, travelled among the Chanaanites, sojourned among the Philistines, lived some time in Egypt; and in all appearance conversed with all those nations without any apparent difficulty. This circumstance plainly proves, that all these nations at that time spoke nearly the same language. The nations had not yet begun to improve their respective dialects, nor to deviate in any great measure from the monosyllabic tongue of the Hebrews. With respect to the language of Chanaan, afterwards the Phœnician, its similarity to the Hebrew is obvious from the names of gods, men, cities, mountains, rivers, &c. which are the very same in both tongues, as might be shown in numberless cases, were this a proper place for etymological researches.

Before we dismiss this part of our subject, we would wish to gratify our unlearned readers with a brief account of the Hebrew letters, and of the Maioretical points which have been in a manner ingrafted on these letters. In the course of this deduction, we shall endeavour to follow such authors as are allowed to have handled that matter with the greatest accuracy, learning, and perspicuity. If, upon any occasion, we should be tempted to hazard a conjecture of our own, it is cheerfully submitted to the candour of the public.

Much has been written, and numberless hypotheses proposed, with a view to investigate the origin of *alphabetical writing*. To give even an abridged account of all these, would fill many volumes. The most plausible, in our opinion, is that which supposes that the primary characters employed by men were the figures of material objects, analogous to those of the Mexicans, so often mentioned by the authors who have

* Clem. Alex. Strom. Euseb. Chron. lib. 7. Epiph. Hæret. August. &c. † Deut. ch. xxxii. vers. 8.

(1) The Egyptians might not eat bread with the Hebrews, for that is an abomination to the Egyptians. The Philistines (Samuel I. p. 27) always call the Israelites *Hebrews* by way of reproach.

Hebrew Language.
24
Origin of alphabet c writing.

have written the history of that people at the era of the Spanish invasion of their country. As this plan was too much circumscribed to be generally useful, hieroglyphical figures were in process of time invented as subsidiaries to this contracted orthography. In this scheme, we imagine, the process was somewhat more extensive. A *lion* might be sketched, to import fierceness or valour; an *ox*, to denote strength; a *fly*, to signify swiftness; a *hare*, to intimate timorousness, &c.

The next step in this process would naturally extend to the inventing and appropriating of a few arbitrary characters, for representing abstract ideas, and other relations, which could not be well ascertained by the methods above-mentioned. These arbitrary signs might readily acquire a currency by compact, as money and medals do over a great part of the world.— Upon this plan we imagine the ancient Chinese formed their language.

But neither the picture nor the hieroglyphic, nor the method of denoting *ideas* by arbitrary characters appropriated by compact, could ever have arrived at such perfection as to answer all the purposes of ideal communication. The grand desideratum then would be to fabricate characters to represent simple sounds, and to reduce these characters to so small a number as to be easily learned and preserved in the memory. In this attempt the Chinese have notoriously failed; their letters, or rather their characters, are so numerous, that few, if any, of their most learned and industrious authors, have been able to learn and retain the whole catalogue. Indeed those people are not able to conceive how any combinations of 20 or 30 characters should be competent to answer all the purposes of written language.

Many different nations have claimed the honour of this invention. The Greeks ascribed it to the Phœnicians; and consequently used the word *φαινηξισμ**, to all the Phœnician, in the same sense with *αυτονομαζισμ*, to read; and consequently the poet † ascribes the invention to the same ingenious people. The Greeks borrowed their letters from the Phœnicians, and of course looked up to them as the inventors.

Others have attributed the invention to the Egyptians. That people ascribed every useful and ingenious invention to their Thyoth, or Mercury Trimegistus. Plato seems to have believed this tradition (κ), and pretends to record a dispute between the king of Egypt that then reigned and this personage, with respect to the influence that the art of alphabetic writing might possibly have upon the improvements of mankind in science and liberal arts. Diodorus the Sicilian ‡ gives a similar history of the same invention, but carries it back to the reign of Osiris.

Pliny informs us ||, that Gellius attributed letters to the same Egyptian Mercury, and others to the Syrians; but that for “his part, he thought that the Assyrian letters were eternal.” That learned Roman then imagined, that the Assyrian letters had existed at

a period prior to all the records of history; which was in fact the case. By the Assyrian letters, he most mean the Chaldaic, and by the Syrian probably the Hebrew. The earliest Greek historians generally confound the Jews with the Syrians. Herodotus, enumerating the people who had * learned civilization from the Egyptians, mentions the Syrians of Palestine; and elsewhere he tells us, that he had been † the Syrians, and took Cadiz, a large and populous city belonging to that people. Hence it is evident that the Syrian alphabet, or the Syrian letters, were the same with the Hebrew. That the Assyrian or Chaldaic and Hebrew languages were the same, has, we hope, been fully proved already: that their letters were the same in their original structure, can scarce be controverted. These letters, we think, were antediluvian: whether, to use the expression of Plato, they were dictated by some god, or fabricated by some man divinely inspired. As this opinion may admit some dispute, we shall take the liberty to subjoin our reasons.

1. It appears that the era of this invention is buried in impenetrable obscurity. Had an invention of such capital importance to mankind been made in the postdiluvian ages, we imagine the author would have been commemorated in the historical annals of the country where he lived (L).

2. The art of writing in alphabetical characters, according to the sacred records, was practised at so early a period, that there was not a long enough interval between that and the deluge to give birth to that noble invention. If we consider the state of the world during some ages after that disastrous event, we shall quickly be convinced that little respite could be found from the labour and industry indispensably requisite to provide the necessaries, and only a few of the conveniences, of life. Such a state of things was certainly most unfavourable to the invention of those arts and improvements which contribute nothing towards procuring the accommodations of life. The consequence is obvious.

Moses has recorded the history of the creation, of a few of the capital transactions of the antediluvian world, the birth, the age, the death, of the lineal descendants of Seth. He has preserved the dimensions of the ark, the duration of the universal deluge, its effects upon man and all terrestrial animals, the population of the world by the posterity of Noah, the age, &c. of the patriarchs of the line of Shem, from which his own ancestors had sprung. To this he has subjoined the petty occurrences which diversified the lives of Abraham, Isaac, and Jacob, and their descendants. Whence did the historian derive his information? Most probably either from written records then existing, or from divine inspiration. Tradition is a fallible guide; and in many cases the accounts are so minutely precise, as to defy the power of that species of conveyance. The inspired author might probably have extracted

Hebrew
Language.

tracted his abridgment from written memoirs, or histories of the transactions of his ancestors regularly transmitted from the most early periods. These annals he probably abridged, as Ezra did afterwards the history of the Kings of Israel. If this was the case, as it most probably was, the art of writing in alphabeti-

cal letters must have been known and practised many ages before Moses. It has indeed been contended, that the Jewish decalogue, inscribed upon two tables of stone, was the very first specimen of alphabetical writing. The arguments adduced in proof of this fact are lame and inconclusive (M). Had that been the

Hebrew
Language.

(M) The most ingenious and plausible of those arguments which have fallen under our observation, is given by Mr Johnson vicar of Cranbrook, a writer of great learning and piety, who flourished in the beginning of the present century, and whose works deserve to be more generally known than we have reason to think they are at present. After endeavouring to prove that alphabetical writing was not practised before the era of Moses, and expatiating upon the difficulty of the invention, this excellent scholar attempts to show, that the original Hebrew alphabet was actually communicated to the Jewish legislator at the same time with the two tables of the law. "I know not (says he) any just cause why the law should be *written by God*, or by an *angel* at his command, except it were for want of a man that could well perform this part. This could give no addition of authority to the law, especially after it had been published in that astonishing and miraculous manner at Mount Sinai. The true writing of the original was indeed perfectly adjusted, and precisely ascertained to all future ages, by God's giving a copy of it under his own hand: but this, I conceive, had been done altogether as effectually by God's dictating every word to Moses, had he been capable of performing the office of an amanuensis." The learned writer goes on to suppose, that it was for the purpose of *teaching Moses the alphabet*, that God detained him forty days in the mount; and thence he concludes, that the Decalogue was the first writing in alphabetical characters, and that those characters were a divine, and not a human invention.

It is always rash, if not something worse, to conceive reasons not assigned by God himself, for any particular transaction of his with those men whom he from time to time inspired with heavenly wisdom. That it was *not* for the purpose of teaching Moses the alphabet that God detained him forty days in the mount, when he gave him the two tables of the law, seems evident from his detaining him just as many days when he gave him the second tables after the first were broken. If the legislator of the Jews had not been sufficiently instructed in the art of reading during his first stay in the mount, he would have been detained longer; and it is not conceivable, that though in a fit of pious passion he was so far thrown off his guard as to break the two tables, his mind was so totally unhinged by the idolatry of his countrymen, as to forget completely an art which, by the supposition, the Supreme Being had spent *forty days* in teaching him! "But if Moses could, at his first ascent into the mount, perform the office of an amanuensis, why are the original tables said to have been written by the finger of God, and not by him who wrote the *second*?" We pretend not to say why they were written by God rather than man; but we think there is sufficient evidence, that by whomsoever they were written, the characters employed were altogether unknown. The Hebrew alphabet, without the Masoretic points, is confessedly defective; and every man who is in any degree acquainted with the language, and is not under the influence of inveterate prejudice, will readily admit that those points are no improvement. But we cannot, very well suppose an art invented by infinite wisdom, to fall short of the utmost perfection of which it is capable: an alphabet communicated to man by God, would undoubtedly have been free both from defects and from redundancies; we may suppose it would have had a distinct character for every simple sound, and been at least as perfect as the Greek or the Roman.

But we need not fill our pages with reasonings of this kind against the hypothesis maintained by Mr Johnson. We know that "Moses wrote all the words of the *Lord*" i. e. the substance of all that had been delivered in *Exod.* xx. xxi. xxii. xxiii. before he was called up into the mount to receive the table of stone; nay, that he had long before been commanded by God himself, to "write in a book" an account of the victory obtained over Amalek (*Exod.* xvii. 14). All this, indeed, the learned writer was aware of; and to reconcile it with his hypothesis, he frames another, more improbable than even that which it is meant to support. "It is not unreasonable (says he) to believe that God had written these tables of stone, and put them in mount Horeb, from the time that by his angel he had there first appeared to Moses; and that, therefore all the time after, while he kept Joshua's sheep thereabouts, he had free access to those tables, and perused them at discretion." But if belief should rest upon evidence, we beg leave to reply, that to believe all this would be in the highest degree unreasonable: for there is not a single hint in Scripture of the tables having been written at so early a period, or upon such an occasion, as God's first appearance to Moses in the burning bush. We know how reluctant Moses was to go upon the embassy to which he was then appointed; and it is strange, we think passing strange, that when he records so faithfully his own backwardness, and the means made use of by God to reconcile him to the arduous undertaking, he should make no mention of these important tables, if at that period he had known any thing of their existence. Besides all this, is it not wonderful, if Moses had been practising the art of writing, as our author supposes, from the time of the burning bush to the giving of the law, he should then have stood in need of *forty days* teaching from God, to enable him to *read* with ease the first tables, and of other forty, to enable him to *write* the second? This gave such a mean view of the natural capacity of the Hebrew legislator as renders the hypothesis which implies it wholly incredible. See a *Collection of Discourses, &c. in two volumes, by the reverend John Johnson, A. M. vicar of Cranbrook in Kent.*

Hebrew
Language.

the case, some notice must have been taken of so palpable a circumstance. Moses wrote out his history, his laws, and his memoirs; and it appears plainly from the text, that all the learned among his countrymen could read them. Writing was then no novel invention in the age of the Jewish legislator, but current and generally known at that era.

The patriarch J. blived at an earlier period (x). In that book we find many allusions to the art of writing, and some passages which plainly prove its existence. This shows that alphabetical characters were not confined to the chosen seed, since Job was in all probability a descendant of Huz, the eldest son of Nahor* the brother of Abraham. From this circumstance, we think we may fairly conclude, that this art was known and practised in the family of Terah the father of Abraham.

There was certainly a tradition among the Jews in the age of Josephus, that writing was an antediluvian invention †. That historian pretends, that the descendants of Seth erected two pillars, the one of stone and the other of brick, and inscribed upon them their astronomical observations and other improvements.— This legend shows that there did exist such an opinion of the antiquity of the art of writing.

4. There must have been a tradition to the same purpose among the Chaldeans, since the writers who have copied from Berofus, the celebrated Chaldean historian (o), speak of alphabetical writing as an art well known among the antediluvians. According to them, Oannes the Chaldean legislator gave his disciples “an insight into letters and science. This person also wrote concerning the generation of mankind, of their different pursuits, of civil polity, &c. Immediately before the deluge (say they) the god Cronus appeared to Siltuthrus or Xifuthrus, and commanded him to commit to writing the beginning, improvement, and conclusion of all things down to the present term, and to bury these accounts securely in the temple of the Sun at Seppara.” All these traditions may be deemed fabulous in the main; but still they evince that such an opinion was current, and that though the use of letters was not indeed eternal (p), it was, however, prior to all the records of history; and of course, we think, an antediluvian discovery.

This original alphabet, whatever it was, and however constituted, was, we think, preserved in the family of Noah, and from it conveyed down to succeeding generations. If we can then discover the original Hebrew alphabet, we shall be able to investigate the primary species of letters expressive of those articulate sounds, by which man is in a great measure distinguished from the brute creation. Whatever

VOL. XIV.

might be the nature of that alphabet, we are convinced that the ancient Jews deemed it a treasure, therefore preserved it pure and unaltered till the Babylonish captivity. If, then, any monuments are still extant inscribed with letters prior to that event, we may rest assured that these are the remains of the original alphabet.

These have, from time to time, been dug up at Jerusalem, and other parts of Judea, coins and medals, and medallions, inscribed with letters of a form very different from those square letters in which the Hebrew Scriptures are now written.

When the Samaritan Pentateuch was discovered (q), it evidently appeared that the inscriptions on these medals and coins were drawn in genuine Samaritan characters. The learned Abbe Bartholera, in his dissertation “on the two medals of Antigonus king of Judea, one of the later Asmonean princes, proves that all the inscriptions on the coins and medals of Jonathan and Simon Maccabeus, and also on his, were invariably in the Samaritan character, down to the 40th year before the christian era.”

It were easy to prove, from the Mishna and Jerusalem talmud, that the Scriptures publicly read in the synagogues to the end of the second century were written in the Samaritan character, we mean in the same character with the Pentateuch in question. As the ancient Hebrew, however, ceased to be the vulgar language of the Jews after their return from the Babylonish captivity, the copies of the Bible, especially in private hands, were accompanied with a Chaldaic paraphrase; and at length the original Hebrew character fell into disuse, and the Chaldaic was universally adopted.

It now appears that the letters inscribed on the ancient coins and medals of the Jews were written in the Samaritan form, and that the Scriptures were written in the very same characters: we shall therefore leave it to our readers to judge whether (considering the implacable hatred which subsisted between these two nations) it be likely that the one copied from the other; or at least that the Jews preferred to the beautiful letters used by their ancestors, the rude and inelegant characters of their most detested rivals. If, then, the inscriptions on the coins and medals were actually in the characters of the Samaritan Pentateuch (and it is absurd to suppose that the Jews borrowed them from the Samaritans), the consequence plainly is, that the letters of the inscriptions were those of the original Hebrew alphabet, coeval with that language, which we dare to maintain was the first upon earth.

It may, perhaps, be thought rather superfluous to

mention, that the Samaritan colonists, whom the kings of Assyria planted in the cities of Samaria (R), were natives of countries where Chaldaic letters were current, and who were probably ignorant of the Hebrew language and characters. When those colonists embraced the Jewish religion, they procured a copy of the Hebrew Pentateuch written in its native character, which, from superstition, they preserved inviolate as they received it; and from it were copied successively the others which were current in Syria and Palestine when Archbishop Usher procured his.

From the reasons above exhibited, we hope it will appear, that if the Hebrew alphabet, as it appears in the Samaritan Pentateuch, was not the primitive one, it was at least that in which the Holy Scriptures were first committed to writing.

Reg.
Which was
introduced
by Ezra.

Scaliger has inferred, from a passage in Eusebius *, and another in St Jerom †, that Ezra, when he reformed the Jewish church, transcribed the Scriptures from the ancient characters of the Hebrews into the square letters of the Chaldeans. This, he thinks, was done for the use of those Jews who, being born during the captivity, knew no other alphabet than that of the people among whom they were educated.—This account of the matter, though probable in itself, and supported by passages from both Talmuds, has been attacked by Buxtorf with great learning and no less acrimony. Scaliger, however, has been followed by a crowd of learned men (s), whose opinion is now pretty generally espoused by the sacred critics.

Having said so much concerning the Hebrew alphabet in the preceding pages, we find ourselves laid under a kind of necessity of hazarding a few strictures on the vowels and Masoretic points; the *first* essential, and the *last* an appendage, of that ancient language. The number of the one, and the nature, antiquity, and necessity of the other, in order to read the language with propriety and with discrimination, have been the subject of much and often illiberal controversy among philological writers. To enter into a minute detail of the arguments on either side, would require a complete volume: we shall, therefore, briefly exhibit the state of the controversy, and then adduce a few observations, which, in our opinion, ought to determine the question.

The controversy then is, whether the Hebrews used any vowels; or whether the points, which are now called by that name, were substituted instead of them? or if they were, whether they be as old as Mo-

ses, or were invented by Ezra, or by the Massorites (r)? This controversy has exercised the wits of the most learned critics of the two last centuries, and is still far enough from being determined in the present. The Jews maintain, that these vowel points (v) were delivered to Moses along with the tables of the law; and consequently hold them as sacred as they do the letters themselves. Many Christian authors who have handled this subject, though they do not affirm their divine original, nor their extravagant antiquity, pretend, however, that they are the only proper vowels in the language, and regulate and ascertain its true pronunciation. Though they differ from the Jews with respect to the origin of these points, they yet allow them a pretty high antiquity, ascribing them to Ezra and the members of the great synagogue.

At length, however, about the middle of the 16th century, Elias Levita, a learned German Jew who then flourished at Rome, discovered the delusion, and made it appear that these appendages had never been in use till after the writing of the talmuds, about 500 years after Christ. This innovation raised Elias a multitude of adversaries, both of his own countrymen and Christians. Among the latter appeared the two Buxtorfs, the father and the son, who produced some cabalistical books of great antiquity (x), at least in the opinion of the Jews, in which there was express mention of the points. The Buxtorfs were answered by Capellus and other critics ‡, till Father Morinus §, having examined all that had been urged on both sides, produced his learned dissertation on that subject; against which there has been nothing replied of any consequence, whilst his work has been universally admired, and his opinion confirmed by those that have beaten the same field after him.

According to this learned father, it plainly appears that neither Origen, nor St Jerome, nor even the compilers of the talmuds, knew any thing of what has been called the vowel points; and yet these books, according to the same author were not finished till the seventh century. Even the Jewish rabbis who wrote during the eighth and ninth centuries, according to him, were not in the least acquainted with these points. He adds, that the first vestiges he could trace of them were in the writings of *rabbi Ben Affer* chief of the western, and of *rabbi Ben Naphtali* chief of the eastern school, that is, about the middle of the tenth century; so that they can hardly be said to be older than the beginning of that period.

The He-
brew
characters.

Hebrew Language.

Some learned men (v) have ascribed the invention of the vowel points in question to the rabbis of the school of Tiberias: which, according to them, flourished about the middle of the second century. This opinion is by no means probable, because it appears plain from history, that before that period all the Jewish seminaries in that province were destroyed, and their heads forced into exile. Some of these retired into Babylonia, and settled at Sora, Naberda, and Pumbeditha, where they established famous universities. After this era there remained no more any rabbinical schools in Judaea, headed by professors capable of undertaking this difficult operation, nor indeed of sufficient authority to recommend it to general practice, had they been ever so thoroughly qualified for executing it.

Capellus and father Motin, who contend for the late introduction of the vowel-points, acknowledge that there can certainly be no language without vocal sounds, which are indeed the soul and essence of speech; but they affirm that the Hebrew alphabet actually contains vowel characters, as well as the Greek and Latin and the alphabets of modern Europe. These are *aleph, he, vau, yod*. These they call the *mattres lectionis*, or, if you please, the parents of reading. To these some, we think, very properly, add *ain* or *vin, ajin*. These, they conclude, perform exactly the same office in Hebrew that their descendants do in Greek. It is indeed agreed upon all hands, that the Greek alphabet is derived from the Phœnician, which is known to be the same with the Samaritan or Hebrew. This position we shall prove more fully when we come to trace the origin of the Greek tongue. Hitherto the analogy is not only plausible, but the resemblance precise. The Hebrews and Samaritans employed these vowels exactly in the same manner with the Greeks; and so all was easy and natural.

53 The mattres lectionis.

34 Objections answered.

But the asserters of the Masoretic system maintain, that the letters mentioned above are not vowels but consonants or aspirations, or any thing you please but vocal letters. These they endeavour to prove from their use among the Arabians, Persians, and other oriental nations: But to us it appears abundantly strange to suppose that the Greeks pronounced *beta, gama, delta*, &c. exactly as the Hebrews and the Phœnicians did, and yet at the same time did not adopt their mode of pronunciation with respect to the five letters under consideration. To this argument we think every objection must undoubtedly yield. The Greeks borrowed their letters from the Phœnicians; these letters were the Hebrew or Samaritan. The Greeks wrote and (z) pronounced all the other letters of their alphabet, except the five in question, in the same manner with their originals of the east: if they did so, it obviously follows that the Greek and oriental office of these letters was the same.

Another objection to reading the Hebrew without the aid of the Masoretic vowel points, arises from the consideration, that without these there will be a

great number of radical Hebrew words, be *היה* and verbs, without any vowel intervening among the consonants, which is certainly absurd. Notwithstanding this supposed absurdity, it is a well known fact, that all the copies of the Hebrew Scriptures, used in the Jewish synagogues throughout the world, are written or printed without points. These copies are deemed sacred, and kept in a coffer with the greatest care, in allusion to the ark of the testimony in the tabernacle and temple. The priest, however, reads the portions of the law and hagiographa without any difficulty. The same is done by the remnants of the Samaritans at this day. Every oriental scholar knows that the people of these countries look upon consonants as the stamina of words. Accordingly, in writing letters, in dispatches upon business, and all affairs of small moment, the vowels are generally omitted. It is obvious, that in every original language the sound of the vowels is variable and of little importance. Such was the case with the Hebrew tongue: Nor do we think that the natives of the country would find it a matter of much difficulty to learn to read without the help of the vowels. They knew the words beforehand, and so might readily enough learn by practice what vowels were to be inserted.

Hebrew Language.

When the Hebrew became a dead language, as it certainly was in a great measure to the vulgar after the return from the Babylonish captivity; such subsidaries might, we think, have been useful, and of course might possibly have been adopted for the use of the vulgar: but the scribe, the lawyer, and the learned rabbi, probably disdained such beggarly elements. We shall in this place hazard a conjecture, which, to us at least, is altogether new. We imagine that the Phœnicians, who were an inventive, ingenious people, had, prior to the age of Cadmus, who first brought their letters into Greece, adopted the more commodious method of inserting the vowels in their proper places: whereas the Jews, zealously attached to the customs of their ancestors, continued to write and read without them. In this manner the Gephyraei †, who were the followers of Cadmus, communicated them to the Iones their neighbours. We are convinced that the materials of the Greek tongue are to be gleaned up in the east; and upon that ground have often endeavoured to trace the origin of Greek words in the Hebrew, Phœnician, Chaldean, and Arabian languages. Reading without the vowel points we have seldom failed in our search; but when we followed the method of reading by the Masoretic points, we seldom succeeded; and this, we believe, every man of tolerable erudition who will make a trial will find by experience to be true. This argument appears to us superior to every objection. Upon this basis, the most learned Bochart has erected his etymological fabric, which will be admired by the learned and ingenious as long as philology shall be cultivated by men.

* Herod. lib. i. cap. 56.

35 Proof that the Masoretic points are modern.

(v) See Buxtorf the father, in Tiber. cap. 5, 6, 7 Buxtorf the son de Antiq. Punct. P. II. 11.
 (z) This is so true, that according to Helychias and Sudias, *שׁוֹמֵר*, to act the Phœnician, signified "to read."

Hebrew Language.

It has been urged by the zealots for the Masoretic system, that the Arabians and Persians employ the vowel points. That they do so at present is readily granted but whether they did so from the beginning seems to be the question. That Arabia was overspread with Jewish exiles at a very early period, is abundantly certain. It was natural for them to retire to a land where they would not hear of war nor the sound of the trumpet. Accordingly we find that, prior to the age of the Arabian impostor, Arabia swarmed with Jewish settlements. From these Jews, it is highly probable that their neighbours learned the use of the points in question; which in the course of their conquests the Saracens communicated to the Persians. It has been alleged with great show of reason, that without the vowel points, it is often impossible to develop the genuine signification of many words which occur frequently in the language; many words of different and sometimes opposite significations are written with exactly the same consonants. Without the points then, how are we to know the distinction? In answer to this objection, we beg leave to observe, that, during the first period of a language, it is impossible that there should not occur a number of similar sounds of different significations. This is surely to be attributed to the poverty of the language. When a few terms have been once fabricated, men will rather annex new significations to old terms, than be at the expence of time or thought to invent new ones. This must have been the case with the Hebrew in particular; and indeed no language on earth is without instances of this inconveniency, which, however, in a living tongue, is easily overcome by a difference of accent, tone, gesture, pronunciation; all which, we think, might obviate the difficulty.

From the preceding arguments, we think ourselves authorized to infer that the Masora is a novel system, utterly unknown to the most ancient Jews, and never admitted into those copies of the Scriptures which were deemed most sacred and most authentic by that people.

According to ORIGIN.

Breſhith bara Eloëim eth aſamaim oueth aares.

Upon the whole, we presume to give it as our opinion, that in the most early periods, the vowels *alph*, *he*, *jad* or *ya*, *vava* or *ava* and perhaps *oin* or *ajin*, were regularly written wherever they were founded. This to us appears plain from the practice of the ancient Greeks. It is agreed on all hands that the Samaritan and Phœnician alphabets were the same; and that the former was that of the Jews originally. The Phœnicians certainly wrote the vowels exactly, for so did the Greeks who copied their alphabet; if the Phœnicians wrote their vowels, so then did the Jews of the age of Cadmus; but Cadmus was contemporary with some of the earliest judges of Israel; the consequence is evident, namely, that the Jews wrote their

With respect to the original introduction of the points, we agree with the learned and judicious * Dr Prideaux, who imagines that they were gradually introduced after the Hebrew became a dead language, with a view to facilitate the learning to read that language, more especially among the vulgar. By whom they were introduced, we think, cannot easily be determined; nor is it probable that they were all introduced at once, or by one and the same person. They have been ascribed to Ezra by many, for no other reason that we can discover but to enhance their authenticity, and because the sentiment is analogous to the other articles of reformation established by that holy priest. If our curious reader should not be satisfied with the preceding detail, we must remit him to Capellus and Morinus on the one side, and the two Buxtorfs, Schultens, and Dr James Robertson professor of oriental languages in the university of Edinburgh, on the other. This learned orientalist, in his dissertation prefixed to his *Clavis Pentateuchi*, has collected and arranged, with a true spirit of criticism, every thing that has been advanced in favour of the Masoretical system.—*Si Pergama deserta defendi possent, etiam hæc defensa fuissent.*

St Origen, who flourished about the beginning of the 3d century, was a profound Hebrew scholar. He published a most laborious and learned work, which is generally called the *Hexapla*, because it consisted of six columns; the first of which contained the Hebrew text; the second the same text, but written in Greek characters; the third column exhibited the version of Aquila; the fourth, that of Symmachus; the fifth, the Septuagint; and the sixth, the version of Theodotian. In some fragments of that vast work which are still extant, we have a specimen of the manner in which the Hebrew was pronounced in the third century, by which it appears that it was very different from that which results from observing the Masoretical points. The following is an instance copied from the beginning of Genesis.

According to the MASORITES.

Bereſhith bara Elohim eth aſham-ajim veeth aarets.
 Vearets ajetha thòou vabou, vekhofhek gnal penè
 theom verouakh elohim merakhepheth gnal penè ham-
 maim.
 Vajomer elohim jehi or, vajchi or.
 Vajare elohim eth aor ki tob vajabedel elohim bein
 aor ouèin hakhofhek.

vowels as late as the arrival of that Colony-chief in Greece. We ought naturally to judge of the Hebrew by the Chaldaic, Syriac, and Arabian, its sister dialects. All these languages in ancient times had their vowels regularly inserted; and why not the Hebrew in the same manner with the rest?

As these first vowels, which were coeval with the other letters, often varied in their sound and application, the points, in all appearance, were first invented and employed to ascertain their different sounds in different connections. Other marks might be invented to point out the various tones of voice, like the *tauca* or accents, with which the vowels were to be pronounced, as was done among the latter Greeks. In

 And the practice of the ancient Greeks.

process

Hebrew Language. process of time, in order to promote celerity of writing, the vowels were omitted, and the points substituted in their place.

Before we conclude our observations on the Hebrew language, we ought, perhaps, to make an apology for omitting to interlard our details with quotations from the two Talmuds, the Mishna, the Gemara, the Cabbalas, and a multitude of rabbinical writers which are commonly cited upon such an occasion. We believe we could have quoted almost numberless passages from the two Buxtorfs, Father Morin, Capellus, and other Hebrew critics, with no great trouble to ourselves, and little emolument to the far greater part of our readers. But our opinion is, that such a pedantic display of philological erudition would probably have excited the mirth of our learned and roused the indignation of our unlearned, readers. Our wish is to gratify readers of both descriptions, by contributing to the edification of one class without disgusting the other.

We cannot, we imagine, handsomely take leave of the sacred language without giving a brief detail of those excellencies which, in our opinion, give it a just claim to the superiority over those other tongues which have sometimes contended with it for the prize of antiquity: and of these the following in our apprehension deserve particular notice.

38
Excellencies of the Hebrew language.

If this language may claim any advantage over its antagonists, with respect to its being rather a mother than a daughter to any of them, it is undoubtedly in consequence of its simplicity, its purity, its energy, its fecundity of expressions and significations. In all these, notwithstanding its paucity of words, it excels the vast variety of other languages which are its cognate dialects. To these we may add the significancy of the names, both of men and brutes; the nature and properties of the latter of which are more clearly and more fully exhibited by their names in this than in any other tongue hitherto known. Besides, its well authenticated antiquity and the venerable tone of its writings surpass any thing left upon record in any other dialect now extant in the world. These extraordinary qualities excite our admiration at present under every disadvantage; and from this circumstance we may infer its incomparable beauty in the age of the Jewish legislator, and what effects it would naturally produce, could we know it now as it was spoken and written in the days of David and Solomon.

As far, however, as we understand it in its present mutilated condition, and are able to judge of its character from those few books that have come down to our time, we plainly perceive that its genius is simple, primitive, natural, and exactly conformable to the character of those uncultivated patriarchs who used it themselves, and transmitted it to their descendants in its native purity and simplicity. Its words are comparatively few, yet concise and expressive; derived from a very small number of radicals, without the artificial composition of modern languages. No tongue, ancient or modern, can rival it in the happy and rich fecundity of its verbs, resulting from the variety and significancy of its conjugations; which are so admirably arranged and diversified, that by changing a letter or two of the primitive, they express the various modes of acting, suffering, motion, rest, &c. in such a pre-

cise and significant manner, that frequently in one word they convey an idea which, in any other language, would require a tedious paraphrase. These positions might easily be illustrated by numerous examples; but to the Hebrew scholar these would be superfluous, and to the illiterate class neither interesting nor entertaining.

To these we may add the monosyllabic tone of the language, which, by a few prefixes and affixes without affecting the radix, varies the signification almost at pleasure, while the method of affixing the person to the verb exhibits the gender of the object introduced. In the nouns of this language there is no flexion except what is necessary to point out the difference of gender and number. Its cases are distinguished by articles, which are only single letters at the beginning of the word: the pronouns are only single letters affixed; and the prepositions are of the same character prefixed to words. Its words follow one another in an easy and natural arrangement, without intricacy or transposition, without suspending the attention or involving the sense by intricate and artificial periods. All these striking and peculiar excellencies combined, plainly demonstrate the beauty, the stability, and antiquity of the language under consideration.

We would not, however, be thought to insinuate that this tongue continued altogether without changes and imperfections. We admit that many radical words of it were lost in a course of ages, and that foreign ones were substituted in their place. The long sojourning of the Israelites in Egypt, and their close connection with that people, even *quoad sacra*, must have introduced a multitude of Egyptian vocables and phrases into the vulgar dialect at least, which must have gradually incorporated with the written language, and in process of time have become parts of its essence. In Egypt, the Israelites imbibed these principles of idolatry which nothing less than the final extirpation of their polity could eradicate. If that people were so obstinately attached to the Egyptian idolatry, it is not very probable that they would be averse from the Egyptian language. Besides, the Scripture informs us, that there came up out of Egypt a mixed multitude; a circumstance which must have infected the Hebrew tongue with the dialect of Egypt. As none of the genuine Hebrew radicals exceed three letters, whatever words exceed that number in their radical state may be justly deemed of foreign extraction.

Some Hebrew critics have thought that verbs constitute the radicals of the whole language; but this opinion appears to us ill founded: for though many Hebrew nouns are undoubtedly derived from verbs, we find at the same time numbers of the latter deduced from the former.

Before we conclude our detail of the Hebrew tongue, a few of our readers may possibly imagine that we ought to give some account of the Hutchinsonian system; a system so highly in vogue not many years ago. But as this allegorical scheme of interpretation is now in a manner exploded, we shall beg leave to remit our curious Hebraist to Mr Holloway's Originals, a small book in 2 vols 8vo, but replete with multifarious erudition, especially in the Hutchinsonian style and character.—*Edis sit pons au oron.*

Arabic Language

SECT. *The Arabic Language.*

43 Arabic Language originally Hebrew.

We now proceed to give some account of the Arabian language, which is evidently one of the sister dialects of the Hebrew. Both, we imagine, were originally the same; the former highly improved and enlarged; the latter in appearance, retaining its original simplicity and rude aspect, spoken by a people of a genius by no means inventive. In this inquiry, too, as in the former we shall spare ourselves the trouble of descending to the grammatical minutie of the tongue; a method which we are persuaded, would neither gratify our learned nor edify our unlearned readers. To those who are inclined to acquire the first elements of that various, copious, and highly improved tongue, we beg to recommend *Epist. Rudimenta Ling. Arab. Celsi Gram. Arab.* the Dissertations of Horri, translated by the elder Schultens; Mr Richardson's *Persic and Arabic Gram.* &c.

We have pronounced the Hebrew and Arabian sister dialects; a relation which, as far as we know, has been seldom controverted; but we think there is authentic historical evidence that they were positively one and the same, at a period when the one as well as the other appeared in its infant unadorned simplicity. The following detail will, we hope, fully authenticate the truth of our position.

2 Gen. x 25.

“Unto Eber (says the Scripture*) were born two sons. The name of one was Peleg, because in his days the earth was divided: and his brother's name was Joktan,” or rather Yoktan. This last says the sacred historian, “had thirteen sons; and their dwelling reached from Metha (Mocha) to Sephar (A),” a mount of the east. According to this account, the descendants of Yoktan possessed all the maritime coast of Arabia from Metha (Mocha) to mount Sephar towards the east of that peninsula. Moses, describing the rivers of paradise, tells us, that one of the branches of that river † “encompassed the whole land of Havilah, where there was great store of gold.” Havilah was the twelfth son of Yoktan, whom the Arabians call Kobtan; and consequently his territory was situated towards the eastern limit of the possessions of the posterity of the youngest son of Eber. Yoktan or Kobtan was too young to be concerned in the building of the tower; and consequently retained the language of his family, which was undoubtedly the Hebrew. His descendants must have carried the same language into their respective settlements, where it must have been transmitted to succeeding generations. The original language of all the tribes of the Arabians who inhabit a vast tract of country along the southern shore, according to this deduction, was that of their father Kobtan, that is, the Hebrew. Indeed, the most learned Arabians of modern times unanimously acknowledge this patriarch as the founder of their language as well as of their nation.

4 Gen. ii. 11

The other districts of Arabia were peopled by the offspring of Abraham. The Ishmaelites, the posterity

of that patriarch by Hagar, penetrated into the very centre of the peninsula; incorporated, and in process of time became one people with the Kobtanites. Another region was possessed of the children of the same holy man by Chetumah his second wife. The Moabites, Ammonites, Edomites, Amalekites, &c. who settled in the various regions of Arabia Petraea, were all branches of Abraham's family, and used the same language with their great progenitor. The Scripture indeed speaks of people who inhabited the country last mentioned prior to the branches of Abraham's family; but these, according to the same history were extirpated by the former. The conclusion then is, if we credit the Mosiac account, that all the inhabitants of the three divisions of Arabia did, in the earliest periods, universally use the Hebrew tongue.

There was, we are sensible, a region of Arabia inhabited by the Cushim, or descendants of Cush. This district was situated on the confines of Babylonia. Our translators have confounded this country with the modern Ethiopia; and have consequently ascribed the exploits of the Arabian Cushim to the Ethiopians. The Arabian kings of Babylonia were of these Cushim. These were conquered and expelled Babylonia by the Chaldeim. These spoke the Chaldean dialect, as will appear when we come to speak of that of the Assyrians. Here the candid reader is desired to reflect that the Hebrew and Chaldaic are cognate dialects.

The foregoing proofs, deduced from the Mosiac history, will be corroborated by a mass of internal evidence in the succeeding parts of our inquiry.

The Arabic tongue, originally pure Hebrew, was in process of time greatly transformed and altered from its simple unsoftened state. The Arabians were divided into many different tribes; a circumstance which naturally produced many different dialects. These, however, were not of foreign growth. No foreign enemy ever conquered those independent hords. The Persians, Greeks, and Romans, sometimes attempted to invade their territories; but the roughness of the ground, the scarcity of forage, the penury of water, and their natural bravery, always protected them. They were indeed once invaded by the Assyrians or Ethiopians with some show of success; but these invaders were in a short time expelled the country. Their language, of consequence, was never adulterated with foreign words or exotic phrases and idioms. Whatever augmentations or improvements it received were derived from the genius and industry of the natives, and not from adventitious or imported acquisitions. From this circumstance we may justly infer, that the Arabian tongue was a long time stationary, and of course differed in no considerable degree from its Hebrew archetype. The learned Schultens, in his commentary on Job, hath shown, to the conviction of every candid inquirer, that it is impossible to understand that sublime composition without having recourse to the Arabic idioms. That patriarch was a Chuzite. His country might be reckoned a parts of Arabia. His three friends were actually

41 Gradually deviated from that simplicity.

Arabians,

(A) Sephar, in the Septuagint Σοφρα: and in some editions Σοφρα hence probably Σαφρα, *Orig. in Job.* cap. xxii. ver. 14. *σαφρα τρις ποτ Ερημια Σοφρα τρις Αρσανη ελαι.*

Arabic Language.

Arabians, being the descendants of Ishmael and Esau. His country bordered upon that of the predatory Chaldeans, who were an Arabian banditti. When we consider all these circumstances *in cumulo*, we are strongly inclined to believe that the book of Job was actually written in Arabic, as the language stood at that period; which, according to the most probable opinion, could not have been later than the age of Moses. The learned are generally agreed that this whole book, the three first chapters excepted, is a poetical composition, replete with the most brilliant and most magnificent imagery, the boldest, the justest, and most gorgeous tropes and allusions, and a grandeur of sentiment wholly divine. Whoever has read the poetical compositions of the modern Arabians, on divine subjects, with any degree of taste, will, we flatter ourselves, discover a striking similarity both of diction and sentiment. Be this as it may, we think there is no reason to conclude that the Arabic dialect deviated much from the Hebrew standard prior to the Christian era.

42 The two principal dialects of Arabia.

Of those different dialects which prevailed among the various tribes among which the peninsula of Arabia was divided, the principal were the Hemyaret and the Koreish. Though some of these were tributary to the Tobbas, or Hemyarat sovereign of Arabia Felix, yet they took no great pains to cultivate the language of that province, and of course these people did not thoroughly understand it. As for the independent tribes, they had no temptation to cultivate any other language than their own.

The Koreish tribe was the noblest and the most learned of all the western Arabs; and the kaaba, or square temple of Mecca, was before the era of Mohammed solely under their protection. This temple drew annually a great concourse of pilgrims from every Arabian tribe, and indeed from every other country where the Sabian religion prevailed. The language of the Koreish was studied with emulation by the neighbouring tribes. Numbers of the pilgrims were people of the first rank, and possessed all the science peculiar to their country or their age. Great fairs were held during their residence at Mecca, and a variety of gay amusements filled up the intervals of their religious duties. In these entertainments literary compositions bore the highest and most distinguished rank; every man of genius considering not his own reputation alone, but even that of his nation or his tribe, as interested in his success. Poetry and rhetoric were chiefly esteemed and admired; the first being looked upon as highly ornamental, and the other as a necessary accomplishment in the education of every leading man. An assembly at a place called *Ocaab*, had been in consequence established about the end of the sixth century, where all were admitted to a rivalry of genius. The merits of their respective productions were impartially determined by the assembly at large; and the most approved of their poems, written on silk, in characters of gold, were with much solemnity suspended in the temple as the highest mark of honour which could be conferred on literary merit. These poems were called the *Moallabat*, "suspended," or *Moalhabat*, "golden." Seven of these are still preserved in many European libraries.

43 The dialect of the Koreish became the politest, and why.

From this uncommon attention to promote emula-

tion, and refine their language, the dialect of the Koreish became the purest, the richest, and the most polite, of all the Arabian idioms. It was double with a kind of predilection; and about the beginning of the seventh century it was the general language of Arabia, the other dialects being either incorporated with it, or sliding gradually into disuse. By this singular idiomatic union the Arabic has acquired a prodigious fecundity; whilst the luxuriance of synonyms, and the equivocal or opposite senses of the same or similar words, hath furnished their writers with a wonderful power of indulging, in the fullest range, their favourite passion for antithesis and quaint allusion. One instance of this we have in the word *vah*; which signifies a *prince*, a *friend*, and also a *flour*. This same word, with the change of one letter only, becomes *vah*; which, without equivocation, imports a *sovereign*. Examples of this kind occur in almost every page of every Arabic dictionary.

Arabic Language.

But all these advantages of this incomparable language are merely modern, and do not reach higher than the beginning of the sixth century. Prior to that era, as we have observed above, a variety of dialects obtained; and as the Arabs were by their situation in a manner sequestered from all the rest of mankind, it may not perhaps be superfluous to enquire briefly into the cause and origin of this instantaneous and universal change.

44 This superiority modern.

For a course of more than 20 centuries the Arabians had been shut up within the narrow limits of their own peninsula, and in a great measure secluded from the rest of the world. Their commerce with India was purely mercantile, and little calculated to excite or promote intellectual improvements. They traded with the Egyptians from time immemorial; but since the invasion and usurpation of the pastor kings, every shepherd, that is, every Arabian, was an abomination to the Egyptians. From that quarter, therefore, they could not derive much intellectual improvement. Besides, when an extensive territory is parcelled out among a number of petty sects or clans, the feuds and contests which originate from interfering interests and territorial disputes, leave but little time, and less inclination, for the culture of the mind. In these circumstances, the military art alone will be cultivated, and the profession of arms alone will be deemed honourable. Of consequence, we find that, in the general opinion, poetry, rhetoric, and the profession of arms, were the only sciences cultivated by the people in question. As for the science of arms, we are convinced that it was both studied and practised at a very early period; but as to the two former, we imagine they were very late acquisitions, and sprung from some circumstance external and adventitious.

The tribe of the Koreish were much engaged in commerce. They exported frankincense, myrrh, cassia, galbanum, and other drugs and spices, to Damascus, Tripoli, Palmyra, and other commercial cities of Syria and its neighbourhood. Upon these occasions the Arabian traders must have become acquainted with the Greek language, and perhaps with the more amusing and affecting parts of the Grecian literature. They might hear of the high renown of Homer and Demosthenes; and it is not impossible that some of them might be able to read their compositions.

body

Arabic
Language.

body knows with what unremitting ardour the learned Arabs, under the first Khalifs, perused and translated the philosophical works of the Grecian sages. The very same spirit might animate their predecessors, though they wanted learning, and perhaps public encouragement, to arouse their exertions. From this quarter, we think the Arabs may have learned to admire, and then to imitate, the Grecian worthies.

The Ptolemies of Egypt were the professed patrons of commerce as well as of learning. Under these princes all nations were invited to trade with that happy country. The Arabs, now no longer fettered by Egyptian jealousy, carried their precious commodities to Alexandria; where the Grecian literature, though no longer in its meridian splendour, shone however with a clear unclouded lustre. The court of the first Ptolemies was the resort of all the most celebrated geniuses of Greece and of the age; in a word, Alexandria was the native land of learning and ingenuity. Here the ingenious Arab must have heard the praises of learning incessantly proclaimed; must have been often present at the public exhibitions of the poets and orators; and even though he did not understand them exactly, might be charmed with the melody of the diction, and struck with surprise at their effects on the audience. The reader will please to reflect, that the Arabian traders were the first men of the nation, both with respect to birth, learning, and fortune. These wise men, to use the language of Scripture, inspired with the natural curiosity of their race, might hear of the celebrated Olympic games, the public recitations before that assembly, and the glorious prize bestowed upon the conquerors. Such information might animate them to institute something parallel at Mecca, with a view to improve their language, and at the same time to derive honour and emolument to themselves. The Koreishite might promise themselves the like advantages from the establishment of the fair and assembly at Ocah, as the natives of Elis drew from the institution of the Olympic games. For these reasons, we conjecture the literary competitions at the place just mentioned were instituted at so late a period, though the nation had existed more than 2000 years before the establishment of this anniversary. Upon the whole, we are inclined to believe, that the Arabs, notwithstanding all the fine things recorded of them by their own poetical historians, and believed perhaps too easily by those of other countries, were in the days of ignorance like the earliest Romans, *latores et famulari*. For our part, we think it by no means probable that a people of that character should after so long a course of years, have stumbled upon so laudable and so beneficial an institution, without taking the hint from some foreign one of a similar complexion. This we acknowledge is only a conjecture, and as such it is submitted to the judgment of the reader.

There were, as has been observed above, two principal dialects of the original Arabic: the Hamyarite spoken by the genuine Arabs, and the Koreishite or pure Arabic, which at last became the general language of that people. The former of these inclined towards the Syriac or Chaldean; the latter being, according to them, the language of Ishmael, was deeply tinged with the Hebrew idiom. The oriental writers tell us

that Terah, the grandfather of Hamyar, was the first whose language deviated from the Syriac to the Arabic. Hence, say they, the Hamyaritic dialect must have approached nearer to the purity of the Syriac, and of consequence must have been more remote from the true genius of the Arabic than that of any of the other tribes. The fact seems to stand thus: The Hamyarites were neighbours to the Chaldeans and Syrians, and consequently were connected with those people by commerce, wars, alliances, &c. This circumstance is introduced into their language many phrases and idioms from both these nations. That Terah was concerned in adulterating the dialect of the Hamyarites, is a mere oriental legend, fabricated by the Arabs after they began to peruse the Hebrew Scriptures. The Koreish being situated in the centre of Arabia, were less exposed to intercourse with foreigners, and therefore preserved their language more pure and unaltered.

The learned well know, that the Koran was written in the dialect of the Koreish; a circumstance which communicated additional splendour to that branch of the Arabian tongue. It has been proved, that the language of the original inhabitants of Arabia was genuine Hebrew; but upon this supposition a question will arise, namely, whether the Arabians actually preserved their original tongue pure and unsophisticated during a space of 3000 years, which elapsed between the deluge and the birth of Mohammed? or, whether during that period, according to the ordinary course of human affairs, it underwent many changes and deviations from the original standard?

The admirers of that language strenuously maintain the former position; others, who are more moderate in their attachment, are disposed to admit the latter. Charon observes of the oriental languages in general, that they do not vary and fluctuate with time like the European tongues *. “Ce qu'il y a de plus admirable, dit il, et de plus remarquable, dans ces langues, c'est, qu'elles ne changent point, et n'ont point changé du tout, soit à l'égard de termes, soit à l'égard du tour: rien n'y est, ni nouveau ni vieux, nulle bonne façon de parler, n'a été dite en crédit. L'Alcoran, par exemple, est aujourd'hui, comme il y a mille années, le modèle de plus pure, plus courte, et plus éloquente diction.” It is not to our purpose to transcribe the remaining part of the author's reflection upon this subject: From the above it plainly appears that he concludes, that the Arabian tongue has suffered no change since the publication of the Koran; and at the same time insinuates, that it had continued invariable in its original purity through all ages, from the days of Kobtan to the appearance of that book. Whether both or either of these sentiments is properly authenticated will appear in the sequel.

The learned Dr Robertson, professor of oriental languages in the university of Edinburgh, informs us, that the Arabians, in order to preserve the purity of their language, strictly prohibited their merchants, who were obliged to go abroad for the sake of commerce, all commerce with strange women. We know not where this injunction is recorded, but certainly it was a most terrible interdiction to an amorous son of the desert. If such a prohibition actually existed, we suspect it originated from some other source than the fear of corrupting their language. Be that as it may, the Doc-

tor, as well as the great Schultens, is clearly of opinion, that the language in question, though divided into a great number of streams and canals, still flowed pure and limpid in its course.

Our readers who are acquainted with the history of the orientals are already apprized of the steady attachment of those people to ancient customs and institutions. We readily allow, that in the article of Language this same predilection is abundantly obvious; but every oriental scholar must confess, that the style of the Koran is at this day in a manner obsolete, and become almost a dead language. This fact, we believe will not be questioned. If the Arabian has deviated so very considerably from the standard of the Koran in little more than 1000 years, and that too after an archetype is ascertained; by a parity of reason we may infer, that much greater deviations must have affected the language in the space of 3000 years.

48 The style of the Koran now obsolete,

It is universally allowed by such as maintain the unfulfilled purity of the Arabian tongue, that it was originally the same with the Hebrew, or with the ancient Syriac and Chaldaic. Let any one now compare the words, idioms, and phraseology of the Koran with the remains of those three languages, and we think we may venture to affirm that the difference will be palpable. This circumstance, one would think, indicates in the strongest terms a remarkable alteration.

The Arabs themselves are agreed, that, notwithstanding the amazing fecundity of their language, vast numbers of its radical terms have been irrecoverably lost. But this loss could not be supplied without either fabricating new words or borrowing them from foreign languages. To the latter method we have seen their aversion; and must therefore conclude that they adopted the former.

The Chaldeans, Syrians, and Phœnicians, had made innovations on their language at a very early period, even before conquests were undertaken: We see no reason to suppose that the Arabs did not innovate as well as their nearest neighbours: the Hamyarites did actually innovate.

There are, we think, very strong reasons to believe, that Job was an Arabian, and flourished prior to Moses, perhaps as early as Jacob. The style, the genius, the figurative tone of the composition; the amazing sublimity of the sentiments, the allusions, the pathos, the boldness, the variety, and irregularity; the poetical enthusiasm which pervade the whole poem, strongly breathe the Arabian spirit: indeed the very diction is peculiar to that single book, and differs widely from that of the Psalms and every poetical part of the sacred canon. If we compare this book with Mohammed's Koran, we shall scarce find any resemblance of words or phraseology; but a wonderful similarity of figures, enthusiasm, and elevation of sentiments.

49 And resembling the Hebrew in its phraseology.

We are then led to conclude, that the Arabic did actually lose and gain a multitude of vocables between the era of its first establishment among the descendants of Joktan and Ishmael and the birth of the impostor.

The art of writing was introduced among the Arabs at a very late period: Without the assistance of this art one would think it altogether impossible to preserve any language in its primæval purity and simplicity. Our curious readers may here expect some ac-

count of the Arabic character: the following is the most probable one we have been able to collect on that subject.

Arabic Language.

It is generally agreed, that the art of writing was known among the Hamyrites or Homerites at a very early period. These people were foreigners of Arabia during a course of many ages. Their character was somewhat perplexed and confused. It was called *Mofnad*, from the mutual connection of the letters. The alphabet of these people resembled that of the Hebrews both in the number and order of the letters, and is called *alg'id beviz* †, from the first ten letters of the Hebrew alphabet, artificially thrown together.

Pococke's Syriac. Hist. Arab. 52 Art of writing among the Hamyrites. Id. Ibid.

“And this word (says the learned Chardin †) *a, b, g, d*, is formed of the four letters which were heretofore the first in the Arabian language, as they are still in that of the Hebrews.” The same traveller is positive that these were the ancient characters of the Arabs; that they differed from Caphite letters, which were afterwards introduced; and that they were furnished with vowel points. These, we imagine, were the first rude sketches of the Chaldean character, which probably the Hamyarites retained in their pristine unpolished form, after they had been polished and reduced to a more elegant size by the original inventors.

Vol. III. p. 153.

Monuments bearing inscriptions in these characters are, they tell us, still to be seen in some places of Arabia. Some were engraved on rocks; and to these we think it probable that the patriarch Job alludes in those passages where he seems to intimate an inclination to have his sufferings recorded in a book, and graven in the rock for ever. All the Arabians agree, that the dialect of the Hamyarites inclined towards the Syriac or Chaldean. This we have imputed to the connection of that people with the Chaldeans, who lived in their neighbourhood. If the Hamyaritic dialect was infected with the Syriac or Chaldaic, there can be no doubt that they derived their letters from the same quarter.

51 In Chaldaic characters.

We conclude then, that the Hamyarites knew the art of writing from the earliest antiquity, and that the letters they employed were the rude Chaldaic in their unimproved state §. Some of the Arabians do indeed hold, that Ishmael was the first author of letters; but that his characters were rude and indistinct, without any interval between letters or words, and that these were adopted by Kedar and his other children: but this tradition hath met with little credit.

§ Pococke Orat. de Ling. Arab.

With respect to the highly polished Koreishites, it is agreed on all hands, that they were unacquainted with the use of letters till a few years before the birth of Mohammed. Two difficulties here present themselves. The first is, how the Koreishite dialect, without the art of writing, happened to excel all the other dialects of the Arabic tongue, assisted by that art, apparently so necessary for preserving a language in its original purity. The second is still, we think, rather greater, namely, how the Koreish learned that most useful art at so late a period as the sixth century. It is a well known fact, that ever after the Babylonish captivity Arabia swarmed with Jewish villages, in which the art of writing was generally known; and almost at the beginning of the Christian era; multitudes of Christians retired to the same country, in order to avoid the persecutions which they suffered in the Roman empire. In these circumstances, we think it rather

52 Art of writing among the Koreishites.

Arabic
Language.

ther strange, that the Koreishites, highly polished and acute as they were, never thought of laying hold on the opportunity of learning an art so very useful. These two problems we leave to be solved by our more learned readers.

But however they be solved, it is universally acknowledged, that the Koreish were ignorant of letters till a few years before the birth of their prophet. Ebn Chalican (b) one of their most celebrated historians, informs us, that Moramar the son of Morra, an Arabian, a native of Anbaris, a city of Irak (c), first invented alphabetical characters, and taught his countrymen to use them, from whom this noble invention was derived to the Koreishites. These letters, though neither beautiful nor convenient, were long used by the Arabs. They were denominated *Cuphite*, from *Cupha* a city of Irak. In this character the original copy of the Koran was written. These we think were the original clumsy characters which were retained by the vulgar after the beautiful square Chaldaic letters were invented; and probably used by priests, philosophers, and the learned in general. These letters are often at this day used by the Arabs for the titles of books and public inscriptions.

53
Improved
about 300
years after
Moham-
med.

Abauli the son of Moela §, about 300 years after the death of Mohammed, found out a more elegant and more expeditious character. This invention of Abauli was afterwards carried to perfection by Ebn Bowla, who died in the year of the Hegira 413, when Kader was caliph of Bagdad. This character, with little variation, obtains at this day. As we think this article of some importance, we shall, for the sake of our unlearned readers, transcribe an excellent account of this whole matter from the very learned Schultens.

“The Cuphic characters, says he, which had been brought from the region of the Chaldeans to the province of Hejaz, and to Mecca its capital, in the age of Mohammed, was employed by the Koreishites, and in it the koran was first written. But as this character was rude and clumsy, in consequence of its size, and ill calculated for expedition, Abauli Ebn Moela devised a more elegant and expeditious one. This person was vizir to Haradius the 41st caliph, who began to reign in the year of the hegira 322. Accordingly, in the 10th century, under this emperor of the Saracens, the form of the Arabian alphabet underwent a change; and the former clumsy embarrassed character was made to give way to the polished, easy, and expeditious type. Regarding this expedition alone, the author of the invention left very few vowel characters; and as the Hebrew manner of writing admits five long ones and five short in different shapes, he taught how to express all the vowels, both long and short, suitably to the genius of the language, by three, or rather by two, small points, without any danger of a mistake: an abbreviation truly deserving applause and admiration: for by placing a very small line above $\overset{\cdot}{\text{a}}$ he expressed *a* and *e*; and by placing the same below $\underset{\cdot}{\text{a}}$ he meant to imitate *i* only. To the other short

ones, *o* and *u*, he assigned a small $\overset{\cdot}{\text{u}}$ above. In order to represent the long ones, he called in the *matres lectionis*, the quiescent letters ā, ē, ī so that *pkata* with *clif* i. e. *timated a* and *o* long, i. e. *kametz* and *cholem*; *jod* placed after *k. fram* became *tzeri* and *chirek* long. *Waw* annexed to *damma* made *sebur k.*”

Arabic
Language.

In this passage, this great orientalist acknowledges that the vizir above-mentioned, who carried the Arabian alphabet to the pinnacle of perfection, invented and annexed the vowel points for the sake of ease and expedition in writing; from which we may infer, that prior to the tenth century the Arabians had no vowel points; and consequently either read without vowels, or contented themselves with the *matres lectionis* above-mentioned.

The design of the author of the invention in fabricating these points, was confessedly ease and expedition in writing; a circumstance which furnishes a violent presumption that the Hebrew vowel-points were devised and annexed at some late period for the very same purposes.

Some, indeed, have gone so far as to affirm that the Arabians were the original fabricators of the vowel-points. The Arabians † (says the learned Dr Gregory Sharp) were the original authors of the vowel-points. They invented three, called *fatha*, and *damma*, and *kesra*: but these were not in use till several years after Mohammed; for it is certain that the first copies of the koran were without them. The rabbis stole them from the Arabs.” This, however, is carrying the matter too far, since it is certain that the Jews were acquainted with the points in question long before the period above mentioned.

† Diff. on
the Origin
and Const.
of Lang.
&c.

Though it is none of our intention to enter into a minute detail of the peculiarities of this noble language, we cannot omit observing one thing, which indeed belongs to grammar, but is not generally taken notice of by the Arabic grammarians. The roots of verbs in this dialect are universally trilateral; so that the composition of the 28 Arabian letters would give near 22,000 elements of the language. This circumstance demonstrates the surprising extent of it: for although great numbers of its roots are irrecoverably lost, and some perhaps were never in use; yet if we suppose 10,000 of them, without reckoning quadrilaterals to exist, and each of them to admit only five variations, one with another, in forming derivative nouns, the whole language would then consist of 50,000 words, each of which may receive a multitude of changes by the rules of grammar.

54
Surprising
extent of
the Arabic
language.

Again, the Arabic seems to abhor the composition of words, and invariably expresses very complex ideas by circumlocution; so that if a compound word be found in any dialect of that language, we may at once pronounce it of foreign extraction. This is indeed a distinguishing feature in the structure of this tongue, as well as of some of its sister dialects. This circumstance has, in our opinion, contributed not a little to the amazing fecundity of that language: for as every ingredient in the composition of a complex idea requires

a

(b) See this whole detail in Dr Pocock's *Specim. Hist. Arab.* p. 255. et seq.

(c) *Irak*, “*Babylonia*,” from *Erech*, one of the cities built by Nimrod. The Arabians have generally restored the ancient names of places. Thus with them Tyre is *Tzur*, Sidon *Syd*, Egypt *Mezri*, &c.

Arabic Language.

a word to express it, as many words became necessary to complete the language as there were simple ideas to be intimated by discourse. Were all the compounds of the Greek language to be dissolved, as probably once they were, the vocables of that tongue would infinitely exceed the present number.

The Arabic authors boast most unconscionably of the richness and variety of their language. No human understanding, say they is capacious enough to comprehend all its treasures. Inspiration alone can qualify one for exhausting its sources. Ebn Chalawaib, a most renowned grammarian of theirs, has spent a whole volume upon the various names of the lion, which amount to 500; another on the names of the serpent, which make up 200. Mohammed al Firacabodius, affirms that he wrote a book on the usefulness and different denominations of honey, in which he enumerates 80 of them; and after all, he assures that he was still far from having exhausted his subject. To excel in a language so amazingly copious, was certainly a proof of uncommon capacity, and considered as no mean talent even among the Koreihites. Hence Mohammed, when some people were expressing their admiration of the eloquence of the koran, told them that he had been taught by the angel Gabriel the language of Ithamel, which had fallen into desuetude.

§ Pococke's Specimen

In a language so richly replenished with the choicest and most energetic terms, both oratory and poetry were cultivated with ease. All the difficulty consisted in making a choice among words and phrases equally elegant. We may compare one of those poets or orators to a young gentleman, of a taste highly refined, walking into a repository where a profusion of the richest and most elegant dresses are piled up in wild confusion. Our beau is here distressed with variety; but to be able to choose the most handsome and most becoming he must have received from nature a superior good taste; which he must likewise have cultivated by assiduous industry, and by associating with the most genteel company.

55 Oratory and poetry of the Arabs.

The orations of the Arabs were of two kinds, metrical and prosaic. The former they compared to pearls set in gold, and the latter to loose ones. They were ambitious of excelling in both; and whoever did so was highly distinguished. His success in either of those departments was thought to confer honour, not only on his family, but even on his tribe. In their poems were preserved the genealogies of their families, the privileges of their tribes, the memory of their heroes, the exploits of their ancestors, the propriety of their language, the magnificence of banquets, the generosity of their wealthy chiefs and great men, &c. After all, we cannot avoid being of the unpopular opinion, that this mighty parade of eloquence and poetry did not reach backwards above two centuries before the birth of Mohammed, as it certainly vanished at the era of the propagation of his religious institutions. The two succeeding centuries were the reigns of superstition and bloodshed. The voice of the muses is seldom heard amidst the din of arms.

The ancient Arabs, at whatever time poetry began to be in request among them, did not at first write poems of considerable length. They only expressed themselves in metre occasionally, in acute rather than harmonious strains. The Proverbs of Solomon, and

the book of Ecclesiastes seem to be composed in this species of versification. The prosody of the Arabs was never digested into rules till some time after the death of Mohammed; and this is said to have been done by Al Khalti al Farabidi, who lived in the reign of the caliph Naran of Raschid.

Arabic Language.

After so many encomiums on the copiousness of the Arabic tongue, one class of our readers may possibly expect that we should subjoin a brief detail of its genius and character; and this we shall do with all possible brevity.

66 Genius and character of the language.

All the primary or radical words of the language are composed of different combinations of consonants by triads; so that the various combinations and conjunctions of radicals make more than 10,000, even without including those which may arise from the meeting of guttural letters. From this quality of the language has flowed that stability of the dialect which has preserved it pure and entire for so many thousand years, and secured it from those changes and that fluctuation to which most other tongues are subject.

Perhaps notwithstanding its copiousness and variety, no other language can vie with the one in question in point of perspicuity and precision. It is possessed of a brevity and rotundity which, amidst the greatest variety, enables it to express with clearness and energy what could not be expressed in any other tongue without tedious circumlocutions. To this purpose we shall beg leave to transcribe a passage from Bishop Pocock's oration on the Arabic language. As we imagine few of our readers who will have the curiosity to peruse this article can be unacquainted with the Latin tongue, we shall give it as it stands in the original without a translation:

“ Neque in nulla certe laudis parte, mira illa qua, non solum verborum in significando, perspicuitate, sed in prolatione, elegantiae et dulcedini caverunt, sedulitas; quoque, non solum accuriata, inter literas ex significata proportione, sensus vel intentioni, vel remissioni, prout res postulaverit, literarum appositione, subductione, vel juxta organorum, rationem prospexerunt; sed et ne quid delicatulus auribus ingratum, ne quid horridum, aut *αρρηκων* reperiatur, effecerunt Hoc in genere est, quod nusquam in verbo aliquo, genuinae apud Arabes originis, concurrant, non intercedente vocalis alicujus motione consonantes, cum vel tres, vel plures, aliis in linguis frequenter colliduntur. Immo neque, si adsint, quae asperitati remedio sint, vocales, quas libet temere tamen committunt consonantes; sed ita rei natura postulat, ut concurrere debeant illa, quae se invicem, sine asperitatis inductione consequi, et inter se connecti non possunt; illi vel situs, vel literarum mutatione, eas abjiciendo, inferendo, emolliendo, aliisque quibus possent modis remedia quarunt; adeo ab omni, quod vel absorum, vel dissonum est, abhorrent. Quid si nobis fecus videntur, et asperius sonare ab Arabibus prolata, illud auribus nostris, et uani, non linguae imputandum, nec mollius illis sonare nostra, quam eorum nobis censendum. Quin et gutturalium, quae nobis maxima asperitatis cauta videntur, absentiam, ut magnum in lingua Graeca defectum, arguunt Arabes.

The learned Dr Hunt, late professor of the Hebrew and Arabic languages at Oxford, is of the same opinion with the very learned prelate, part of whose oration

Arabic
Language.

tion we have transcribed above, with respect to the delicacy and elegance of the Arabian language:—"Nusquam, mihi credite, (inquit ille) auribus magis pareitur quam in Arabia; nulla lingua a *κακωγορια*, alienior quam Arabica. Quamquam enim nonnullæ ejus literæ minus fortasse fuaviter, immo durius etiam sonuerint, ita tamen Arabes eas temperarunt cum lenibus, duras cum mollibus, graves cum acutis miscendo, voces inde non minus auribus jucundæ, quam pronuntiatio faciles confecerint, totique sermone miram sonorum tam dulcedinem quam varietatem addiderint. Quod quidem orationis modulandæ studium in Corano adeo manifestum est, ut primi Islamismi oppugnatores cum librum magicæ ideo arte scriptum dixerint. Non auribus tantum gratus est Arabismus, sed et animi conceptibus exprimendis aptus, sonos suos sententiis semper accommodans, et felici verborum junctura eorum naturam depingens."

To these we might add quotations from Erpenius's oration on the same subject, from Golius, Schultens, Hottinger, Bochart, and Sir William Jones; besides a whole cloud of oriental witnesses, whose extravagant encomiums would rather astonish than edify the far greater part of our readers. These panegyrics may perhaps be in some measure hyperbolical; but in general we believe them pretty well founded. At the same time we are convinced that the Arabic, however melodious in the ear of a native, sounds harsh and unharmonious in that of a European.

57
Difficulty
of acquiring a
thorough
knowledge
of it.

When we consider the richness and the variety of the Arabic tongue, we are led to conclude, that to acquire a tolerable degree of skill in its idioms, is a more difficult task than is generally imagined; at least some people who have acquired the knowledge of the Greek and Latin, and likewise of the more fashionable modern languages, with facility enough, have found it so. Be that as it may, there are two classes of men who, in our opinion cannot handsomely dispense with the knowledge of that almost universal tongue: the gentleman who is to be employed in the political transactions of the most respectable mercantile company upon earth, in the eastern parts of the world; and the divine, who applies himself to investigate the true purport of the sacred oracles; without this, the former will often find himself embarrassed in both his civil and mercantile negotiations; and the latter will often grope in the dark, when a moderate acquaintance with that tongue would make all sunshine round about him.

Bochart, Hottinger, Schultens, Pocock, Hunt, and Robertson, &c. have taken wonderful pains, and lavished a profusion of learning, in proving the affinity and dialectical cognation between the Hebrew and Arabic. Much of this labour, we think, might have been spared. We presume to affirm, that no person tolerably versed in both languages can read a single paragraph of the Arabic version of the New Testament, or indeed of the Koran itself, without being convinced of the truth of this position: it is but slipping the latter of its adventitious frippery, and the kindred features will immediately appear.

The learned professors of the university of Leyden were the first who entered upon the career of Arabian learning. To them the European students are prin-

cipally indebted for what knowledge of that language they have hitherto been able to attain. Though several Italians have contributed their endeavours, yet the fruit of their labours had been rendered almost useless by more commodious and more accurate works printed in Holland.

Chaldean
language,
&c.

The palm of glory, in this branch of literature, is due to Golius, whose works are equally profound and elegant; so perspicuous in method, that they may always be consulted without fatigue, and read without languor. Erpenius's excellent grammar, and his memorable dictionary, will enable the student to explain the history of *Taimur* by *Ibni Arabshub*. If he has once mastered that sublime work, he will understand the learned *Arabic* better than most of the Khatabs of Constantinople or of Mecca.

The Arabian language, however, notwithstanding all its boasted perfections, has undoubtedly shared the fate of other living languages; it has gradually undergone such considerable alterations, that the Arabic spoke and written in the age of Mohammed may be now regarded as a dead language: it is indeed so widely different from the modern language of Arabia, that it is taught and studied in the college of Mecca just as the Latin is at Rome.

The dialect of the Highlands of Yemen is said to have the nearest analogy to the language of the Koran, because these Highlanders have little intercourse with strangers. The old Arabic is through all the East, like the Latin in Europe, a learned tongue, taught in colleges, and only to be acquired by the perusal of the best authors.

"*Ut folia in sylvis pronos mutantur in annos, &c.*"

SECT. III. *Of the Chaldean, Phœnician, or Ethiopian Abyssinian, and Egyptian Languages.*

As there is a very strict connection and dialectical analogy among these languages, we have arranged them all under one section; especially since what is observed relating to one of them may, without the least straining, be extended to them all. We shall begin with the Chaldaic.

58
Connection
of the
Chaldean,
Phœnician,
Ethiopic,
and Egyptian
languages.

The Chaldeans, or Chasidim, as they are always called in Scripture, were the descendants of Chesed the son of Nabor, the brother of Abraham. The descendants of this patriarch drove the Cushim or Arabians out of Babylonia, and possessed themselves of that country at a very early period. As these Chasidim or Chaldeans were the posterity of Nabor, the descendant of Heber, they undoubtedly spoke the original Hebrew tongue as well as the other branches of that family. But being an ingenious inventive people, they seem to have polished their language with much care and delicacy of taste.

The only genuine remains of the ancient Chaldaic language are to be found in the Hebrew Scriptures; and those are contained in 268 verses, of which we have 200 in Daniel, reaching from verse 4th chapter 2d to chapter 8th exclusive; in Ezra 67, in chapter 4th, 17 verses; chapter 5th, the same number; chapter 6th, 18 verses; and in chapter 7th, 15: in Jeremiah, chapter 10th, there is extant only one verse. From these fragments, compared with the Hebrew

Chaldean Language, &c.

brew, it plainly appears, that the difference between that language and the Chaldaic is scarce equal to that between the Doric and Ionic dialects of the Greek.

Whatever might have been the form of the most ancient Chaldaic letters, it is generally known that the beautiful square characters, in which the Hebrew Scriptures began to be written after the age of Ezra, were current among them at an era prior to the Babylonish captivity. Those elegant character were probably the invention of the Chaldean academies, which were established in various parts of that extensive and fertile country.

59
Chaldean differs little from the Hebrew.

The Chaldean declensions and conjugations differ so little from the Hebrew modifications, that it would be almost superfluous to dwell upon them in this section. The most effectual way to acquire an idea of the ancient, Chaldaic, is to decompound the names confessedly of that dialect, which occur in many places of Scripture. By this method of proceeding, its beautiful structure and expressive energy will be readily comprehended even by the most illiterate classes of our readers. At the same time, we must observe, that the Chaldaic and ancient Syriac bore so near a resemblance to each other, that they have generally been classed under one head.

The first Chaldaic word that occurs in the Old Testament is *bara* "creavit." This word has all along been assigned to the language under consideration; for what reason, we confess we are not able to discover. The greatest part of the Hebrew tongue is now lost. The words *lar*, "a son," and *bara* "creavit," (rather *flavit*), may probably be of that number. Another Scripture word which is often quoted, and always ascribed either to the Syriac or Chaldaic, is *igar* or *jigar jahadutha*, which signifies "a monument of witnesses." Every body knows, that when Jacob and Laban made their compact, the latter denominated the heap of stones reared upon that occasion in this manner; while the former called it *Galeed*, as we now write and pronounce it. This pronunciation, however, does not appear to us altogether genuine. The word is probably compounded of *galgal*, *cumulus*, "a heap," and *yer* *chad*, *aternitas*, *seculum*, "eternity, an age:" so that *galgal yad* *galehad*, or *galaad* as it came to be written afterwards signified an "everlasting heap." Laban then had respect to the end for which the monument was erected; but Jacob alluded to its duration. It appears, however, upon this and every other occasion, when Chaldaic words are mentioned, that *a, a,* was a favourite letter both with the Syrians and Chaldeans. We may likewise observe, that the same people always changed the Hebrew *shin* into *thau*, in order to avoid the serpentine sound of that consonant.

60
Its proper names pure Hebrew.

The Chaldaic names of gods, men, places, &c. which occur in Scripture, appear to be no other than Hebrew polished and improved. *Bel*, *Belus* in Latin, is evidently *בעל Baal*, or we think rather *בעל Bechel*. The Phœnicians, and sometimes the Hebrews, used it to signify the most high. The Chaldeans used their word *Bel* for the same purpose; and because this word originally imported the *High One*, they dignified their first monarch with that name. They denominated their capital city *Ba-bel* which imports the *temple of Bel*, and afterwards *Babylon*, which intimates the *abode or dwelling of our lord the sun*. *Neb* was a name of the

moon among the Babylonians, derived from the Hebrew *נבב nabab*, *vati inari*, "to prophesy." *Azer* was the planet Mars, from *אזר Azer* or *Ezur*, *accinsit*, "to gird," alluding to the girding on of arms. *Abud* was an Assyrian name of the sun, a word deduced from the Hebrew *אבד abud*, *unus*, "one." *Nizar* was the name of an Arabian idol †, which often occurs in the composition of Babylonian names. In Arabic it signifies an eagle: we think, however, that the word is the Hebrew *נצר nazor*, *custodivit, servavit*, "to keep, to preserve." To these names of deities many more might be added, which the nature of our design will not allow us to mention.

Chaldean Language, &c.

* Merob lib. 7. c. 23.
† P. 50. l. c. Specim. H. R. Arab.

Almost all the Chaldean proper names which occur either in sacred or profane history are evidently of Hebrew original, or cognate with that language. We shall subjoin a few examples: *Nabonassar* is evidently compounded of *Nabo* and *nazar*, both Hebrew words. *Nabopolassar* is made up of *Nabo-Pul*, the same with *Bel* and *Azer* or *Azor*, above explained. *Belsis* is made up of *Bel* and *אש Ba*, "fire." *Nebuchadnezzar*, *Belshazzar*, *Beltisazzar*, *Neiglissar*, *Nebuzaradan*, *Rabmag*, *Rabiaris*, *Nergal-Sharezer*, *Rabshakeh*, *Ezrahaddon*, *Merodach*, *Evil Merodach*, and numberless others, are so manifestly reducible to Hebrew vocables, when decompounded, that the oriental scholar will readily distinguish them.

Names of places in the Chaldaic are likewise so nearly Hebrew, that nothing but the dialectical tone separates them. Thus *Ur* of the Chaldeans is actually *אור light*, that city being sacred to the sun; *Sippora* is plainly the Hebrew word *Zipporah*; *Carchemish*, a city on the Euphrates, is evidently compounded of *Kir* or *Kar* "a city," and *Chemosh*, a name of the sun. In short, every Chaldean or old Syrian word now extant, without any difficulty, bewray their Hebrew original. As for their dialectical differences, these we remit to the Chaldaic and Syriac grammars and lexicons.

61
Phœnician language derived from the Hebrew.

We now proceed to the consideration of the Phœnician language, which is known to have been that of the ancient Canaanites. That this was one of the original dialects, and consequently a cognate of the Hebrew, is universally acknowledged. Instead therefore of endeavouring to prove this position, we may refer our readers to the works of the learned Mr Bochart, where that author has in a manner demonstrated this point, by deriving almost all the names of the Phœnician colonies from the Hebrew, upon the supposition that the dialect of those people was closely connected with that tongue. St Augustine *de Civitate Dei*, has observed, that even in his time many of the vulgar in the neighbourhood of Carthage and Hippo spoke a dialect of the old Punic which nearly resembled the Hebrew. Procopius, *de bellis Get.* informs us, that there existed even in his days in Africa a pillar with this inscription in Hebrew; "We rise from the face of Joshua the robber, the son of Nun." The names of all the ancient cities built by the Carthaginians on the coast of Africa are easily reducible to a Hebrew original. The Carthaginian names of persons mentioned in the Greek and Latin history, such as Himilco, Hamilcar, Adrubal, Hannibal, Hanno, Dido, Anna or Hannah, Sophoniba, Gongo, Malherbal, Adherbal, &c. all breathe a Hebrew extraction.

Chaldean
Language,
&c.

The Greeks borrowed a great part of their religious worship from the people of whose language we are treating; of consequence, the names of most of their gods are Phœnician. Almost every one of these is actually Hebrew, as might easily be shown. The names of persons and places mentioned in the fragments of Sanchoniathon, preserved by Eusebius, are all of Hebrew complexion. The names mentioned in the Hebrew scriptures of places which belonged to the Canaanites prior to the invasion of the Israelites under Joshua, are as much Hebrew as those which were afterwards substituted in their stead. The Punic scene in Plautus has been analysed by Bochart and several other learned men, by whom the language has been clearly proved to be deduced from the Hebrew, with some dialectical variations.

The island of Melita (Malta now) was inhabited by a colony of Phœnicians many ages before the Moors took possession of it. Among the vulgar of that island many Punic vocables are current to this day, all which may be readily traced up to the Hebrew fountain. To these we may add many inscriptions on stones, coins, medals, &c. which are certainly Phœnician, and as certainly of Hebrew extraction. We have thrown together these few hints without pursuing them to any great length, as we deemed it unnecessary to dwell long on a point so hackneyed and so generally acknowledged.

62
Origin of
the Ethio-
pians

Before we proceed to treat of the ancient language of the Ethiopians, we find ourselves obliged to hazard a few strictures of the origin of that ancient nation. If we can once settle that single point, the discovery will open an avenue to their primitive dialect, the article about which we are chiefly concerned in the present discussion.

In our Section concerning the Hebrew language, we were led often to mention the patriarch Cush the eldest son of Ham. The posterity of this family-chief under his son Nimrod, possessed themselves of Shinar, afterwards denominated *Chaldea*. These were probably the Arabians whose kings (according to Eusebius, Africanus, and other ancient chronologers) reigned in Babylon during several successive generations. Those were the Cushim or Cushites, whom the learned Mr Bryant has conducted over a great part of the world, and to whose industry and ingenuity he has ascribed almost all the inventions, arts, sciences, laws, policy, religions, &c. which distinguished mankind in the earliest ages.

In process of time, the posterity of Chafid or Chafid called *Chafim* or *Chafim* in the east, and *Chaldeans* in the west, drove out the Cushim, and seized upon their country. The Cushim retired westward, and spread themselves over that part of Arabia situated towards the south east. They probably extended themselves over all the eastern part of that peninsula, from the sea to the wilderness between Arabia and Syria. These were the Ethiopians mentioned in Scripture by a very pardonable inadvertency of our trans-

lators. These, then, we think, were the primitive Cushim.

Josephus informs us³, that all the Asiatics called the Ethiopians of Africa by the name of *Cushim*. This denomination was not given them without good reason: it imports at least, that they deemed them the descendants of Cush; it being the constant practice of the orientals in the early ages to denominate nations and tribes from the name of their great patriarch or founder. The name *Cushim* must then have been given to the Ethiopians, from a persuasion that they were the progeny of the son of Ham who bore that name. By what route soever the Cushim penetrated into that region of Africa which was called by their name, it may be taken for granted that they were the descendants of Cush above mentioned.

It has been observed above, that the posterity of Cush possessed the country of Shinar or Chaldea at a very early period, but were expelled by the Chafidim or Chaldeans. Upon this catastrophe, or perhaps somewhat later, a colony from the fugitive Cushim transported themselves from the south and south east coast of Arabia over the sea, which lies between that country and Ethiopia. However imperfect the art of navigation might be in that age, the distance was so small that they might easily make a voyage cross that narrow sea in open boats, or perhaps in canoes. However that may have been, it cannot be doubted that the tribes on both sides of that branch of the sea were kindred nations.

If, then, both the northern and southern Cushim sprung from the same stock, there can be no doubt that both spoke the same language. The language of the Babylonian Cushim was Chaldaic, and of consequence that of the Ethiopian Cushim was the same. We may therefore rest assured, that whatever changes the Ethiopian dialect may have undergone in the course of 3000 years, it was originally either Chaldaic, or at least a branch of that language. Scaliger informs us, that the Ethiopians call themselves Chaldeans; and that, says he, not without reason, because of those many sacred and profane books which are extant among them, the most elegant and most beautiful are written in a style near that of the Chaldean or Assyrian. Marianus Victorius, who was the first that reduced the Ethiopic tongue to the rules of grammar, tells us in his *Proœmium*, "that the Ethiopians call their tongue Chaldaic; that it springs from the Babylonian; and is very like the Hebrew, Syriac, and Arabic: At the same time (he concludes), that this language may be easily learned by those who are masters of the Hebrew." The learned Bochart, and Bishop Walton in his *Proleg*, are clearly of the same opinion.

The vulgar letters of the Ethiopians, according to Diodorus Siculus, were the same with the sacred characters of the Egyptians (p). From this account, if the Sicilian may be trusted, the sacred letters of these people, concerning which so many wise conjectures

step.

(p) We find the same observation confirmed by Heliodorus (*Ethiop.* lib. x. p. 476.) "The royal letters of the Ethiopians (says he) were the sacred characters of the Egyptians." Calliodorus likewise assures us, "That the letters inscribed upon the Egyptian obelisks were Chaldeans." See Sect. *Shanjerit*.

Chaldean Language, &c. tures have been formed, were actually Chaldaic. To carry on this investigation a little farther, we may observe, that Sir William Jones seems to have proved, by very plausible arguments, that the Shanferit characters were deduced from the Chaldaic. This circumstance affords a presumption that the Ethiopian Cuslim were likewise concerned with the Egyptians; who, as is remarked in the Section concerning the *Shanferit*, probably introduced the religion of the Brahmans into Hindostan. This is advanced as a conjecture only; and yet when we consider the affinity between the Egyptian and Gentoo religions, we are strongly inclined to hope that this surmise may one day be verified by undeniable facts.

The original Ethiopians were a people highly civilized; their laws, their institutions, and especially their religion, were celebrated far and wide. Homer talks in raptures of the piety of the Ethiopians, and sends his gods every now and then to revel 12 days with that devout people. The Sicilian adduces a number of very specious arguments to prove that those two nations had sprung from the same stock. He mentions a similarity of features, of manners, of customs, of laws, of letters, of the fabrication of statutes, of religion, as evidences of the relation between those two neighbouring nations. There was, every body knows, a communion, as to sacred rites, between the two countries. The Egyptians sent annually a deputation of their priests, furnished with the portable statues of their gods, to visit the fanes of the devout Ethiopians. Upon this occasion, a solemn religious banquet was prepared, which lasted 12 days, and of which the priests of both nations were partakers. It was, we imagine, a kind of sacramental institution, by which both parties publicly avouched their agreement in the ceremonies of their religion respectively. These observations plainly show, that the most ancient Ethiopians were a people highly civilized; indeed so much, that the Egyptians were at one time contented to be their scholars. The tone of their language was certainly the same with that of the Chaldeans or Arabian Cuslim, from whom they were descended. We know not whether there are any books in the ancient Ethiopic now extant; so that it is not easy to produce instances of its coincidence with the Chaldaic. Diogenes Laertius* informs us, that Thrasyllus, in his catalogue of the books composed by Democritus, mentions one, *περὶ τῶν ἐν Μερὸν ἑσθῶν γραμμάτων*, concerning the sacred letters in the island of Meroe (E); and another concerning the sacred letters in Balyon. Had these books survived the ravages of time, they would in this age of research and curiosity have determined not only the point under our consideration, but the affinity of sacred rites among the Chaldeans, Ethiopians, and Egyptians.

We have now shown that the Ethiopians were a colony of Cuslites; that the Cuslites were originally sovereigns of Shinar or Chaldaea, and consequently spoke either Chaldaic or a dialect of that tongue;

that their colonists must have used the same language; that the ancient Ethiopians were a people highly polished, and celebrated in the most early ages on account of their virtue and piety. It has likewise appeared, that the common letters of that people were the sacred characters of the Egyptians. The letters, we imagine, were the Cuslites; for which see the Sect. on the *Arabic*. When they were discarded, and the modern substituted in their room, cannot be determined; nor is it we apprehend, a matter of much importance. We shall therefore drop that part of the subject, and refer our curious and inquisitive readers to the very learned Job Ludolf's (F) excellent grammar and Dictionary of the Abyssinian or Geez tongue, where they will find every thing worth knowing on the that subject. We shall endeavour to gratify our readers with a very brief account of the modern Ethiopic or Abyssinian tongue; for which both they and we will be obliged to James Bruce, Esq; that learned, indefatigable, and adventurous traveller; who, by his observations on that country, which he made in person, often at the hazard of his life, has discovered, as it were, a new world both to Europe and Asia.

The most ancient language of Ethiopia, which we shall now call *Abyssinia* (its modern name), according to that gentleman, was the *Geez*, which was spoken by the ancient Cuslites shepherds. This, we should think, approaches nearest to the old Chaldaic. Upon a revolution in that country, the court resided many years in the province of Amhara, where the people spoke a different language, or at least a very different dialect of the same language. During this interval, the *Geez*, or language of the shepherds, was dropt, and retained only in writing, and as a dead language: the sacred Scriptures being in that tongue only saved it from going into disuse. This tongue is exceedingly harsh and unharmonious. It is full of these two letters D and T, in which an accent is put that nearly resembles stammering. Considering the small extent of sea that divides this country from Arabia, we need not wonder that it has great affinity with the Arabic. It is not difficult to be acquired by those who understand any other of the oriental languages; and as the roots of many Hebrew words are only to be found here, it seems to be absolutely necessary to all those who wish to obtain a critical skill in that language.

The Ethiopic alphabet consists of 26 letters, each of which, by a *virgula* or point annexed, varies its sound in such a manner as that those 26 form as it were 62 distinct letters. At first they had but 25 of these original letters, the Latin P being wanting; so that they were obliged to substitute another letter in its place. *Paulus*, for example, they call *Taulus*, *Aulus*, or *Caulus*; *Petros*, they pronounced *Ketros*. At last they substituted T, and added this to the end of their alphabet; giving it the force of P, though it was really a repetition of a character rather than the invention of a new one. Besides these, there are 20 others of the nature of diphthongs: but some of them are

are probably not of the same antiquity with the letters of the alphabet, but have been invented in later times by the scribes for convenience.

The Amharic, during the long banishment of the royal family in Shoa, became the language of the court, and seven new characters were of necessity added to answer the pronunciation of this new language; but no book was ever yet written in any other language than *Gees*. There is an old law in the country handed down by tradition, that whoever shall attempt to translate the Holy Scripture into Amharic or any other language, his throat shall be cut after the manner in which they kill sheep, his family sold to slavery, and their houses razed to the ground.

Before we leave this subject, we may observe that all the ancients, both poets and historians, talk of a double race of Ethiopians; one in India, and another in Africa. What may have given rise to this opinion it is not easy to discover. Perhaps the swarthy complexion of both people may have led them to this sentiment. Eusebius indeed informs us*, that "a numerous colony of people emigrated from the banks of the Indus, and crossing the ocean, fixed their residence in the country now called Ethiopia." For our part, we are rather inclined to believe that the original Ethiopians transported themselves into India, and there perhaps co-operated with the Egyptians in digging the excavations and framing the statues, some of which are still to be seen in that country, and which we have mentioned in another Section. The Greeks called those people *Aethiopes*, *Æthiopes* we believe, from their sun-burnt countenance; but indeed they were very little acquainted either with the country or its inhabitants.

brew.

The most ancient name of Egypt was *Mizraim*, of consequence the Arabians still call it *Mesra*. It was likewise distinguished by other names, such as *Oveana*, *Aeria*, &c. It appears from the sacred historian, that it was inhabited by the descendants of Mizraim the second son of Ham. Mizraim had several sons, who, according to the Scripture account, settled respectively in that country. If we trust to the sacred records, there will be little difficulty in ascertaining the language of the Mizraim. It will appear to be one of the sister dialects of the Hebrew, Phœnician, Arabic, Chaldaic, &c.; and this, to us appears to be the fact. But the origin of that people, their language, religion, laws, and institutions, have been so warped and confounded both by their own historians and those of other countries, that one is scarce able to determine what to believe or what to reject. Herodotus, Diodorus Siculus, Strabo, Ptolemy, and most other ancient geographers and historians, are universally agreed, that Egypt, at least that part of it called *Delta*, was overflowed by the sea, and consequently uninhabitable for many centuries after the dispersion of mankind. When we consider the low situation of the Delta, and the violent current of the tide from the coast of Phœnicia and Palestine towards that shore, we would be almost tempted to adopt this hypothesis; but the fa-

cred records avouch the contrary. According to them, we find Egypt a populous, rich, and flourishing kingdom, as early as the age of Abraham. Had the Lower Egypt been a pool of stagnating water at any time after the general deluge, we think it could not have been drained, cleared, cultivated, and stocked with inhabitants, so early as the days of Abraham.

Chaldean
Language,
&c.

Diodorus Siculus, however, is positive that the Egyptians were a colony of Ethiopians; and this he endeavours to prove by the similarity of features, customs, laws, religious ceremonies, &c. between the two nations. That there was a constant intercourse of good offices between these two branches of the Hæmatæ, cannot be questioned; and that they nearly resembled each other in many respects, is too evident to admit of contradiction. The excavations, originally dug out of the solid rocks of porphyry and marble, in which the natives resided before the plains were drained, have been observed by a most judicious traveller (G) very few years ago. At the same time, the most accurate and judicious travellers (H) who have visited that region in modern times, are generally of opinion that the land has gained nothing on the sea since the period when Herodotus wrote his description of that country; from which circumstance we may be led to conclude, that the idea of the inundation of the Delta is not founded in fact.

§ Lib. 15.
passim.

But even admitting that the Egyptian Delta has acquired nothing from the sea since the age of Herodotus to the present, it certainly does not follow that the region in question was never overflowed by that element; since there are in many parts of the globe, large tracts of land certainly once covered with sea, which have continued to this day in the very same situation in which they were 2000 years ago. We leave the decision of this point to the judgment of our readers.

We have already hinted our opinion of the nature of the Egyptian language; but because Egypt is generally thought to have been the native land of hieroglyphics, and because many are of opinion that hieroglyphical characters were prior to the alphabetical, we shall hazard a few conjectures with respect to that species of writing.

The end of speech, in general is to enable men to communicate their thoughts and conceptions one to another when present; the use of writing is to perform the same office when people are at so great a distance that vocal sounds cannot mutually reach them. Hieroglyphics are said to have been invented to supply this defect. The most ancient languages were every where full of tropes and figures borrowed from several objects. As in that stage of society men have not learned to abstract and generalize, all their ideas are borrowed from such objects as most forcibly strike their senses. This circumstance would naturally suggest to savages the idea of conveying their sentiments to each other, when absent, by delineations of corporeal objects. Thus, if a savage asked a loan of his friend's

68

Egyptian
hierogly-
phics.

(G) See Mr Bruce's Travels, Vol. I,

(H) Mr Bruce, Dr Shaw, Bishop Pocock, Savary, Volney, &c.

Chaldean
Language,
&c.

friend's horse, he might find means to have conveyed to him the figure of that animal; and so of others. This was the very lowest species of ideal communication, and has been styled *picture-writing*.

Necessity would soon impel our savage correspondents to fabricate a method more extensively useful, which would likewise be suggested by the constant use of the metaphorical mode of speech. Some savage leader, more sagacious than the vulgar herd, would observe that certain sensible objects were fitted according to the rules of analogy, to represent certain human passions, and even some abstract ideas; and this would be readily enough adopted by the herd as a new improvement. In this case a *horn* might be the emblem of *power*, a *sword* of *bravery*, a *lion* of *fury*, a *fox* of *cunning*, a *serpent* of *malice*, &c. By and by artificial signs might be contrived to express such ideas as could not readily be denoted by bodily objects. This might be called *symbolical writing*. Such was the foundation of the Chinese characters; and hence that prodigious number of letters of which the written language of that people is composed. Farther they could not proceed, notwithstanding their boasted inventive powers; and farther, we believe no nation ever did proceed, who had once upon a time no other characters but hieroglyphical. The Mexicans, had arrived at the very lowest stage of hieroglyphical writing, but had not taken one step towards alphabetical. The Hurons employ hieroglyphical symbols, but never entertained a single idea of alphabetical. Hieroglyphical characters are the images of objects conveyed to the mind by the organs of vision; alphabetic are arbitrary artificial marks of sound, accommodated by compact to convey to the mind the ideas of objects by the organs of hearing. In a word, we think that there is not the least analogy between these two species to conduct from the one to the other: we are therefore of opinion, that hieroglyphical characters were never the vulgar channels of ideal conveyance among civilized people.

69
Were never
in vulgar
use:

We know that in this point we differ from many learned, judicious, and ingenious writers; some of whom have taken much pains to investigate the intermediate stages through which the fabricators of characters must have passed in their progress from hieroglyphical to alphabetical writing. These writers have adopted a plan analogous to Bishop Wilkins's project of an artificial language. In this theory, we own, we are led to suspect that they supposed all mankind were once upon a time *savages*, and were left to hammer out words, as well as characters, by necessity, ingenuity, experience, practice, &c. For our part, we have endeavoured to prove, in our section on the Hebrew language, that alphabetical writing was an antediluvian invention: and we now lay it down as our opinion, that among all those nations which settled near the centre of civilization, hieroglyphics were comparatively, a modern fabrication.

The orientals are, at this day, extravagantly devoted to allegory and fiction. Plain unadorned truth with them has no charms. Hence that extravagant medley of fables and romance with which all antiquity is replete, and by which all ancient history is disguised and corrupted. Every doctrine of religion, every precept of morality, was tendered to mankind in parables

Vol. XIV.

and proverbs. Hence, says the Scripture, to understand a proverb, the words of the wise, and their dark sayings. The eastern sages involved their maxims in this enigmatical dress for several reasons; to fix the attention of their disciples; to assist their memory: to gratify their allegorical taste; to sharpen their wit and exercise their judgment; and sometimes perhaps to display their own acuteness, ingenuity, and invention.

It was among the ancients an universal opinion, that the most sacred arcana of religion, morality, and the sublime sciences, were not to be communicated to *uninitiated rabble*. For this reason every thing sacred was involved in allegorical darkness.

Here, then, we ought to look for the origin of hieroglyphical or picture-writing among the civilized nations of the east. They did not employ that species of writing because they were ignorant of alphabetical characters, but because they thought fit to conceal the most important heads of their doctrines under hieroglyphical figures. The Egyptian priests were most celebrated for their skill in devising those emblematical representations; but other nations likewise employed them. We learn from the fragments of Berossus the Chaldean historian, preserved by Syncellus and Alexander Polyhistor, that the walls of the temple of Belus at Babylon were covered all over with those emblematical paintings. These characters were called *ερασι*, because they were chiefly employed to represent sacred objects; and *γλυφικα*, because they were originally carved or engraved. Their name points to their original use. Instead of pursuing these observations, which the nature of our design will not permit, we must refer our readers to Herodotus, l. ii. Diodorus Sic. l. i. Strabo, l. xvii. Plut. Isis and Osiris; and among the Christian fathers, to Clem. Alex. Euseb. Præp. Evang.; but chiefly to Horapollo's Hieroglyphica.

From this deduction we would conclude, that this species of writing was an adventitious mode in Egypt, peculiar to the priests, and employed chiefly to exhibit things sacred; and that among all civilized people it did not supersede the use of alphabetical characters, nor did the use of the latter originate from the former. When alphabetical letters were invented, if indeed they were a human invention, they were antecedent to the other in use and extent. The Egyptian priests alone knew the true import of those sacred symbols; and communicated that knowledge first to their own children from generation to generation, then to the initiated, and last of all to the *grandees* of the nation, all of whom were indeed initiated. The hieroglyphics of Egypt were not then the symbols of any sacred occult language; but signs invented by the priests and prophets or wise men, in order to represent their deities, the attributes and perfections of their deities, and the mysterious arcana of their religion, and many other circumstances relating to objects of importance, which were deemed either too sacred or too important to be imparted to the vulgar.

The Egyptians ascribed the invention of letters to a person whom they called *Thoth**, *Thautb*, or *Thyeth*: the Greeks *Ηερακλεις*; and the Romans *Mercurius*. Plato † calls him a god, or a godlike man; † Phadrus. Diodorus ‡ makes him pivity counsellor to Osiris; San- ‡ Lib. i. chonathon

choniathon ap. Euseb. § connects him with the Phœnician Cronus or Saturn. To this Mercury the Egyptians ascribe the invention of all the arts and sciences. He was probably some very eminent inventive genius, who flourished during the first ages of the Egyptian monarchy, and who perhaps taught the rude savages the art of writing.

72
Two kinds
of alphabetic
characters in
Egypt.
|| Lib. I.

According to Diodorus Siculus, the Egyptians had two kinds of letters ||: the one sacred the other common; the former the priests taught their own children, the latter all learned promiscuously. In the sacred characters the rites and ceremonies of their religion were couched; the other was accommodated to the ordinary business of life. Clem. Alexand. mentions three different styles of writing employed by the Egyptians†. “The pupils, who were instructed by the Egyptians, first learned the order and arrangement of the Egyptian letters, which is called *epistolography*, that is, the manner of writing letters; next, the sacred character, which the sacred scribes employed; lastly, the hieroglyphic character, one part of which is expressed by the first elements, and is called *Cyriologic*, that is, *capital*, and the other *symbolic*. Of the symbolic kind, one part explains properly by imitation; and the other is written tropically, that is, in tropes, and figures; and a third by certain enigmatical expressions. Accordingly, when we intend to write the word *sun*, we describe a circle; and when the moon, the figure of that planet appearing horned, conformable to the appearance of that luminary after the change.” In this passage we have an excellent description of the three different modes of writing used by the Egyptians; the common, the sacred, and the hieroglyphic. The last he describes according to its three divisions, in exact conformity to our preceding observations.

† Strom.
lib. 5.

73
The sacred
letters and
language
of Egypt
Chaldaic.

By the description above translated, it plainly appears, that the sacred character of the Egyptians was entirely different from the hieroglyphic; and by this consideration we are in a good measure justified, in supposing, as we have done all along, that the sacred letters of the Egyptians were actually the Chaldaic. The inscriptions on the obelisks mentioned by Cassiodorus, so often quoted, were certainly engraved in the sacred character; and the character in which they were drawn was that above mentioned. If the sacred letters were Chaldaic, the sacred language was probably the same.

The Egyptians pretended, that the Babylonians derived the knowledge of the arts and sciences from them; while, on the other hand, the Babylonians maintained, that the former had been tutored by them. The fact is, they both spoke the same language; used the same religious rites; had applied with equal success to astrology, astronomy, geometry, arithmetic, and the other sciences; of course a rivalry had arisen between the two nations, which laid the foundation of those opposite pretensions.

The most faithful specimen of the vulgar language of the Egyptians, is, we believe, still preserved in the Coptic, which, however, is so replete with Grecisms that it must be difficult to trace it out.

Under the Ptolemies, the Greek was the language of the court, and consequently must have diffused itself over all the country. Hence, we believe, two-thirds of the Coptic are Greek words, diversified by

their terminations, declensions, and conjugations only. To be convinced of the truth of this, our learned and curious readers need only consult Christian Sholtz's Egyptian and Coptic grammar and dictionary, corrected and published by Godfred Woide, Oxford, 1788.

Chaldean
Language,
&c.

The Egyptians and Phœnicians were in a manner cousin-germans, and consequently must have spoken the same language; that is, one of the sister dialects of the Hebrew, Chaldean, Arabian, Cushite, &c.— This is not a mere conjecture; it may be realized by almost numberless examples. It is true, that when Joseph's brethren went down to Egypt, and that ruler designed to converse with them, they could not understand the Egyptian idiom which he spoke; nor would he, had he been actually an Egyptian, have understood them without an interpreter. The only conclusion from this circumstance is, that by this time the Egyptian had deviated considerably from the original language of mankind. The Irish and Welch, every body knows, are only different dialects of the Celtic tongue; and yet experience proves, that a native of Ireland and another of Wales cannot well comprehend each other's language, nor converse intelligibly without an interpreter. The Erse, spoken in the Highlands of Scotland, and the Irish are known to be both branches of the old Celtic? yet a Scotch Highlander and an Irishman can hardly understand each other's speech. By a parity of reason, a Hebrew and an Egyptian might, in the age of Joseph, speak only different dialects of the same original tongue, and yet find it difficult to understand one another. The fact seems to be, the Hebrew dialect had been in a manner stationary; from the migration of Abraham to that period; whereas the Egyptian, being spoken by a powerful, civilized, and highly cultivated people, must have received many improvements, perhaps additions, in the course of near two centuries.

74
The Egyptian
and
Phœnician
languages
the same.

The descendants of Canaan and of Mizraim were strictly connected in their religious ceremonies; they worshipped the same objects namely, the *Hôp of heaven*; they mourned *Ostris* and *Adonis* in concert; they carried on a joint commerce, and, we think, spoke the same language; we may therefore, conclude, that their vulgar letters were nearly the same, both in form, disposition, and number. Their original number was probably 16. viz. five vowels, six mutes, simple and middle, four liquids, and the solitary *ε*.— With these, it is likely, was joined a mark of aspiration, or an *h*, such as we have in the Roman alphabet, and find on some Greek monuments. Cadmus was originally an Egyptian; that leader brought a new set of letters into Greece. These are generally deemed to be Phœnician. They were nearly the same with the ancient Pelasgic, as will be shown in the section of the *Greek language*. The latter, we think, were from Egypt, and consequently the former must have been from the same quarter. Danaus, Perseus, Lelex, &c. were of Egyptian extraction; they too adopted the Cadmean characters, without substituting any of their own.

75
The vulgar
letters of
Egypt
nearly the
same with
the Hebrew
or
Phœnician.

The Jonim, or Ionians, emigrated from Gaza, a colony of Egyptians; and their letters are known to have differed very little from those of Cadmus and the Pelasgi

Pelasgi

Chaldean Language, &c.

Pelafgi. The conclusion, therefore, is, that the vulgar Egyptian letters were the same with the Phœnician.

Chaldean Language, &c.

We are abundantly sensible that there are found upon Egyptian monuments characters altogether different from those we have been describing. At what time, by what people, and to what language, these letters belonged, we will not pretend to determine. The Ethiopians, the Chaldeans, the Persians, the Greeks, the Romans, the Saracens have, at different times, been sovereigns of that unhappy country. Perhaps other nations, whose memory is now buried in oblivion, may have erected monuments, and covered them with inscriptions composed of words taken from different languages, perhaps, upon some occasions, whimsically devised, with a view to perplex the curious antiquaries of future ages. Some of these are composed of hieroglyphics intermingled with alphabetical characters, artificially deranged, in order to render them unintelligible. These we do not pretend to develop: because the most inquisitive and sagacious antiquaries are not yet agreed as to their purport and signification.

76
Egyptian names of Hebrew original.

We shall now go on to show, that most part of the names of persons and places, &c. which have been conveyed down to us, may, in general, be reduced to a Hebrew, Phœnician, Syrian, or Chaldean original. As the first of these languages is most generally known, we shall employ it as our archetype or standard beginning with those terms which occur in Scripture.

The word *Pharaoh*, the title of the *melech* or king of Egypt, is, we think, compounded of two terms, which plainly discover a Hebrew original. According to an oriental tradition, the first who assumed this title was the sovereign of the *royal shepherds*; a race of people from Arabia and Phœnicia. They conquered Egypt at an early period, and kept possession of it for several centuries. They gloried in the title *מֶלֶךְ שׁוֹפְרִים*, or *מֶלֶךְ שׁוֹפְרִים*, which according to Josephus *con. Apion*, signifies "royal shepherds." The word *Pharaoh* seems to be compounded of *פֶּר* *Phar*, "a bullock;" and *רַעַה* *Rachab* "to feed;" hence *פֶּר רַעַה* *Pharachab*, as we think it ought to be written. The name given to Joseph is evidently of kin with the Hebrew; for *zaphnath* differs very little from the Hebrew verb *tzaphan*, which signifies "to hide, to keep secret;" *Paneah* or *Phaneah*, signifies much the same with the Hebrew *Phanah*, *aspexit*: so that the name actually intimates one who sees hidden things; which was certainly the very idea the prince intended to convey by giving him that name.

Potiphar, or *Potipherah*, the name of Joseph's father-in-law, has likewise a dialectical affinity with the Hebrew idiom. In that language *Putab* signifies "to open, to explain," which was one part of the sacerdotal office; and *Phar* imparts "a bullock." Potiphar was then priest of the bullock, that is, the ox, *apis*, sacred to the sun (1). This person was priest or prince of *On*, which according to Cyrillus on Hosea, was an Egyptian name of that luminary. The He-

brew word *hon* or *chon* signifies "power, wealth, sufficiency: a very proper epithet for the sun, who was thought to bestow those blessings. The name of Joseph's wife was *Afenath* or *Afnath*, compounded of *Ishab* "a woman," and *Nath* or *Neit*, an Egyptian name of "Minerva, a votary of Minerva."

Almost all the names of cities belonging to Egypt which are mentioned in Scripture are evidently Hebrew. To be satisfied as to this position, our curious readers may consult Jamieson's *Synologia*, an excellent book very little known. The names of most of the Egyptian deities are significant in the Hebrew tongue; and in that dialect the names appear to have been imposed with great judgment and propriety, plainly indicating some office assigned them, or pointing to some peculiar attribute. We shall produce a few instances.

77
And significant in that language.

Osiris was the great divinity of Egypt; he was certainly the sun. The Egyptians gave their deities a variety of names in allusion to their various offices and attributes. Jablonski has in a manner wearied himself with tracing the signification of this name. In Hebrew we have *Ofsir* "to grow rich, to be enriched." The sun may be called the great enricher of nature, and therefore might properly be called by a name alluding to that quality. *Ifts* was both the moon and the earth. *Ishab* is the Hebrew word for woman, and Horapollon assigns this very derivation. *Anubis* was one of the names of Mercury among the Egyptians: He was always figured with the head of a dog. He accompanied *Ifts* in her peregrinations in quest of Osiris, and frightened away the wild beasts from attacking the princes. In Hebrew, *Nubah* signifies "to bark." Here the analogy, we think is evident. Many Egyptian names begin with *Can*, such as *Canobus*, *Cavopus*, &c. The Hebrew word *Caben* or *Cohen*, *Syr*, *Con* or *Chon*, intimates both a prince and a priest. *Ob* or *Aub*, in Hebrew, imports "a bottle, a flaggon," any thing round and prominent like the human belly. In the language of Egypt it was often applied to the sun, in allusion to his rotundity. In the temple of *Jupiter Ammon* or *Amon*, in the desert of Lybia, there was a statue of the god representing the navel of the human body, which was probably framed in allusion to this fancy. Hence the Pythones, or people who, according to the Scripture, had familiar spirits, were said to prophecy by the inspiration of *Ob*, as the Delphic priestess did by that of Apollo. Again, many Egyptian names end with *sis*, as *Calasiris*, *Termodisiris*. This termination is no doubt a cognate of the Hebrew and Chaldean *sar* or *zar*, signifying "a prince, or grande, &c." The river Nile in the Ethiopic dialect is called *Siris*; that is, we believe the king of rivers. The same flood seems to derive the name by which it is generally known, from the Hebrew *nebel*, "a valley, or torrent running down a valley." The same river was often called *Oceanus*, a word composed of *eg*, or *ec*, *och*, which signifies "a king, a leader," and the Hebrew *oin* "a fountain; so that the word imports the king of fountains. The Hebrews always denominated the land of Egypt

(1) The Septuagint (Gen. xli. v. 45 and 50.) translate *On* by *Πυθων*.

72
Persian
Language.

the land of Mizraim; the Egyptians themselves, in later times, seem to have called it *Agyptus*, "Egypt," which some think is compounded of *Ai*, Hebrew, "an island, a country a province," and *Copt* or *Cypt*, "a famous city in that country."

From this specimen, we hope it will appear that the Egyptian language in the more early ages was one of those dialects into which that of the descendants of the postdiluvian patriarchs was divided, and perhaps subdivided, a few centuries after the deluge. Among all those, we believe, such an affinity will be found, as plainly demonstrates that they originally sprung from one common stock. Here we might easily follow the Egyptian language into Greece; and there we are persuaded we might trace a vast number of Egyptian terms into that tongue, which, however, the nature of this inquiry will not permit. If our learned readers should incline to know more of the affinity of the Egyptian tongue with the others so often mentioned, they may consult Bochart's *Chanaan*, Warton's *Prælog.* Gebelin's *Monde Prim.* Jameſon's *Spicilegia*, &c.

SECT. IV. Of the Persian Language.

THE Persian language is divided into the ancient and modern; the former of which is at this day very imperfectly known, the latter is at present one of the most expressive, and at the same time one of the most highly polished, in the world. We shall, in treating of this language, in compliance with the plan we have all along followed, begin with the ancient.

When Mohammed was born, and ANU'SHIRAV'AN, whom he calls the *just king*, sat on the throne of Persia, two languages were generally prevalent in that empire (κ). The one was called *Deri*, and was the dialect of the court, being only a refined and elegant branch of the *Parſi*, so called from the province of which *Shiraz* is now the capital; and that of the learned, in which most books were composed, and which had the name of *Pahlavi*, either from the heroes who spoke it in former times, or from *p-hlu*, a tract of land which included some considerable cities of *Iran*: The ruder dialects of both were spoken by the rustics of several provinces; and many of these distinct idioms were vernacular, as happens in every kingdom of considerable extent. Besides the *Parſi*, and *Pahlavi*, a very ancient and obscure tongue was known to the priests and philosophers, called the language of the *zend*, because a book on religious and moral duties which they held sacred, and which bore that name, had been written in it; while the *Pazend* or comment on that work was composed in *pahlavi*, as a more popular dialect. The letters of this book were called *zend*, and the language *zavesta*.

The *Zend* and the old *Pahlavi* are now almost extinct in *Iran*, and very few even of the Guebres can read it; while the *Parſi* remaining almost pure in *Shahnameh*, has, by the intermixture of Arabic words, and many imperceptible changes, now become a new language exquisitely polished by a series of fine writers

both in prose and verse, analogous to the different idioms gradually formed in Europe after the subversion of the Roman empire.

The very learned and laborious Sir William Jones is confident that the *Parſi* abounds with words from the Shanſcrit, with no other change than such as may be observed in the numerous dialects of India; that very many Persian imperatives are the roots of Shanſcrit verbs; and that even the nouns and tenses of the Persian verb substantive, which is the model of all the rest, are deducible from the Shanſcrit by an easy and clear analogy. From this he infers that the *Parſi*, like the various idiom dialects, is derived from the language of the Bramins. This conclusion, we imagine, is not altogether just, since by the same train of reasoning we may infer that the Shanſcrit is derived from the *Parſi*.

The same learned gentleman adds, that the multitude of compounds in the Persian language proves that it is not of Arabic but Indian original. This is undoubtedly true; but though the *Parſi* is not of Arabic original, it does not necessarily follow that it is of Shanſcrit. We might with the same propriety, and with an equal show of reason, conclude, that the Greek language is descended of the Shanſcrit, because it too abounds with compounds. We may then rest assured, that neither the one nor the other argument adduced by the ingenious president proves that the *Parſi* tongue is a descendant of the Shanſcrit.

The gentleman so often mentioned, assures us, that the *Zend* bears a strong resemblance to the Shanſcrit; which, however, it might do without being actually derived from it, since we believe every oriental scholar will find that all the languages from the Mediterranean to the utmost coast of Hindostan exhibit very strong signatures of a common original. The *Parſi*, however, not being the original dialect of Iran or Persia, we shall pursue it no farther at present, but return to give some account of the *Pahlavi*, which was probably the primitive language of the country. We have observed above, that the *Pazend* or comment on the *Zend* was composed in the *Pahlavi* for the use of the vulgar. This, according to Sir William, was a dialect of the Chaldaic; and of this assertion he exhibits the following proof.

By the nature of the Chaldean tongue, most words ended in the first long vowel, like *shemaiá* "heaven;" and that very word, unaltered in a single letter, we find in the *Pazend*, together with *lailia* "night," *meyá* "water," *nirá* "fire," *matrá* "rain," and a multitude of others, all Arabic or Hebrew, with a Chaldean termination; so *zamar*, by a beautiful metaphor from *pruning trees*, means in Hebrew, to *compose verses*, and thence, by an easy transition, to *sing* them; now in *Pahlavi* we see the verb *zamarantee* "to sing," with its forms *zamarauemi* "I sing," and *zamaruniá* "he sang;" the verbal terminations of the Persian being added to the Chaldaic root. All these words are integral parts of the language; not adventitious like the Arabic nouns and verbals engrafted on modern Persian.

81
The Pahlavi.

Per&ian Language.

Per&ian Language.

From this reasoning it plainly appears, 1st, that Pahlavi was the ancient language of Persia; and, 2d, that the ancient Persian was a cognate dialect of the Chaldaic, Hebrew, Arabic, Phœnician, &c. M. Anquetil has annexed to his translation of the *Zendavesta* two vocabularies in Zend and Pahlavi, which he found in an approved collection of *Rawayat* or *Traditional Pieces* in modern Persian. His vocabulary of the Pahlavi strongly confirms this opinion concerning the Chaldaic origin of that language. But with respect to the Zend, it abounded with vast numbers of pure Sanscrit words, to such a degree, that six or seven words in ten belonged to that language.

gauge of the Zend and the Sanscrit will be easily accounted for, without making the Hindoos masters of Iran or Persia, and then driving them back to the shores of the Ganges. That the nations of Turan or Scythia did actually over run that country, and make themselves masters of a considerable part of it at different times is vouched by the records and traditions of the Persians themselves. Upon those occasions a number of Tartarian words might be introduced into the country, and acquire a currency among the inhabitants. As the Annals of Ancient Persia have been long since destroyed and consigned to eternal oblivion, it is impossible to ascertain either the extent or duration of these irruptions. Indeed the nature of our design does not call for that investigation.

82
Derived from Chaldaic and Sanscrit, &c.

From this deduction it would appear, that the oldest languages of Persia were Chaldaic and Sanscrit; and that when they had ceased to be vernacular the Pahlavi and Zend were deduced from them respectively, and the Parsi either from the Zend, or immediately from the dialect of the Brahmans; but a I had perhaps a mixture of tartarian; for the best lexicographers assert, that numberless words in ancient Persian are taken from the Cimmerians. With respect to the last of these, we cannot help being of opinion, that colonies of people from the neighbourhood of Persia did transport themselves into Crim Tartary, and perhaps into Europe. These colonists brought along with them those vocables which still occur in their dialect. Emigrants from those quarters must have found their way into Scandinavia, since numberless Persian words are still current in those regions. Perhaps Odin and his followers emigrated from the neighbourhood of Media and Persia, and brought with them the dialect of the nations from whose country they had taken their departure.

In order to corroborate the cognition between the Chaldaic and Pahlavi languages, we shall subjoin a few arguments derived from the Mosaic history, and the other writings of the Old Testament. These we believe will be admitted as irrefragable proofs of the position above advanced by such as admit the authenticity of these records.

84
Proofs from Scripture of the origin of the Pahlavi.

Elam is always allowed to have been the progenitor of the Persians. This patriarch was the eldest son of Shem the son of Noah; and according to the Mosaic account, his posterity settled in the neighbourhood of the descendants of Alhur, Arphaxad, Lud, and Aram, the other sons of Shem. The country where they settled was denominated *Elymais** as late as the beginning of the Christian era. This name was retained till the Saracens conquered and took possession of that country. If this was the case, as it certainly was, the Elamites or Persians spoke a dialect of the primary language, which, in the first Section, we have proved to have been the Hebrew.

* Strabo, lib. 11.

83
The Zend from the same source.

With respect to the Zend, it might well be a dialect of the Sanscrit, and was probably a sacred language; and if so, concealed from the vulgar, and reserved for the offices of religion. If Zoroastres, or Zaradulht as the orientals call him, travelled into Egypt, and was initiated in the mysteries of the Egyptian religion, as some pretend he was, he might be instructed in the sacred dialect of that people by the priests under whom he studied. When that philosopher returned into Persia, and became the apostle of a new religion, he might compose the volume of his laws and religious institutions in the sacred language of his Egyptian tutors. This language then became that of the Magi, who concealed it carefully from the knowledge of the uninitiated, as the priests did in Egypt and the Brahmans in Hindostan.

When the four eastern monarchs invaded the five cities of the plain in Canaan †, Chedorlaomer king of Elam was at the head of the confederacy. Amraphel king of Shinar, that is Babylon or Chaldea, was one of the allies: Arioch king of Elazar was another; and Tidal, king of some scattered nations in the same neighbourhood, was the fourth. That Chedorlaomer was principal in this expedition, is obvious from the historian's detail of the second, where that prince is placed first, and the rest are named *the kings that were with him*. This passage likewise demonstrates, that Elam, Shinar, and Elazar, lay contiguous, and were engaged in the same cause. Wherever the country in question is mentioned in Scripture prior to the era of Daniel and Ezra, it is always under the name of *Elam*. To go about to prove this would be superfluous.

† Gen. chap. xiv.

In our Section on the *Sanscrit* language, we shall give a detail of a number of particulars, which to us seem to furnish a presumption that the language, in question was imported from Egypt into Hindostan. We confess there are not sufficient data to improve these presumptions into absolute certainty; but we hope the time is at hand when the worthy members of the Asiatic Society will discover abundant materials to ascertain the truth of this position. We are the rather inclined to adopt this hypothesis, when we consider the character of Zoroastres in connection with that of the Egyptian Cohens and of the Indian Brahmans.

According to Xenophon‡, the Persians knew nothing of horsemanship before the age of Cyrus: but that historian informs, that after that monarch had introduced the practice of fighting on horseback, they became so fond of it, that no man of rank would deign to fight on foot. Here it ought to be considered, that the historian above mentioned was now writing a moral, military, and political romance; and therefore introduces this anecdote, in order to exalt the character of his hero: so that we are not to suppose that the people under consideration were unacquainted with the art of horsemanship till that period.

‡ Ctes. lib. 1

If this opinion should one day appear to be well-founded we do believe the coincidence between the lan-

The very name *Phars* or *Pharax* is certainly of Hebrew

Perſian
Language.

brew origin, and alludes to the ſkill that people profefſed in horſemanſhip. The original ſeems to be *Pharſab, ungula* "a hoof;" and in the Arabic *Pharas* intimates a *horſe*, and *Pharis* a *horſeman*. Conſequentially the people were denominated *Parſai*, and the country *Parſ*, becauſe they were trained from their infancy to ride the *great horſe*, which indeed they deemed their greateſt honour. This name was perhaps firſt impoſed upon them by the neighbouring nations, and in proceſs of time became their gentle appellation. *Mithras* is generally known to have been the chief divinity of the Perſians; a name which is plainly derived from *Mi kar* "great." We find in Strabo the Perſian god *Amanas*, which is plainly a cognate of *Hamah* the "ſun or fire." Hence we believe comes *Hamarim*, the "heaths or chapels" where the fire ſacred to the ſun was kept burning; which, we believe, the Greeks called *ἱερῶνια* or "fire-temples." Herodotus * mentions a cuſtom among the Perſians, according to which, when they came to engage an enemy, they caſt a rope with a kind of gin at the end of it on their enemy, and by thoſe means endeavoured to entangle and draw him into their power. The people of Perſia who employed this net or gin were called *Sagartes*, from *ſarags, ſarag*, or *ſevig*, a word which in Hebrew, Arabic, and Chaldaic, ſignifies to "hamper or entangle;" hence perhaps the Greek word *σάργα*, a "basket or net." *Sar* or *zar* in Hebrew, Phœnician, Syriac, &c. ſignifies "a lord, a prince," and hence we have the initial ſyllable of the far-famed *zar-tuſht, Zoroaſtres*. In a word, moſt of the Perſian names that occur in the Grecian histories, notwithstanding the ſenſalouſ manner in which they have been diſguiſed and metamorphoſed by the Greeks, may ſtill with a little ſkill and induſtry be traced back to a Hebrew, Chaldaic, Syriac, or Phœnician origin. In the books of Daniel, Ezra, Nehemiah, and Eſther, we find a number of Perſian names which are all of a Hebrew or Chaldaic complexion; to inveſtigate theſe at much greater length would be foreign to the deſign of the preſent article. If our curious reader ſhould incline to be more fully ſatiſfied as to this point, he may conſult Bochart's *Chanaan*, D'Herbelot's *Bib. Orient.* Walton's *Proleg.* &c.

It now appears, we hope to the entire ſatiſfaction of our readers, that the Pahlavi is a remnant of the old Perſian, and that the latter is a cognate branch of the Hebrew, Chaldaic, Syriac, &c. We have likewiſe adduced ſome preſumptive proofs that the Zend was copied from the ſacred language of the Egyptians: we ſhall now endeavour to explain by what changes and revolutions the language firſt mentioned arrived at its preſent ſummit of beauty and perfection.

85
Proſe of
the Perſian
language.

We have obſerved above, that the Sythians, whom the old Perſians called *Σακαι Saca*, and whom the modern call *Turan*, often invaded and over-ran Perſia at a very early period. The conſequence was, an infusion of Scythian or Tartarian terms, with which that language was early impregnated. This in all probability occaſioned the firſt deviation from the original ſtandard. The conqueſts of Alexander, and the dominion of his ſucceſſors, muſt, one would imagine, introduce an inundation of Greek words. That event, however, ſeems to have affected the language in no

conſiderable degree, at leaſt very few Grecian terms occur in the modern Perſian.

Perſian
Language.

The empire of the *Arſacide* or Parthians, we apprehend, produced a very important alteration upon the ancient Perſian. They were a demi-Scythian tribe; and as they conquered the Perſians, retained the dominion of thoſe parts for ſeveral centuries, and actually incorporated with the natives, their language muſt neceſſarily have given a deep tincture to the original dialect of the Perſians. Sir William Jones has obſerved that the letters of the inſcriptions at *Iſſakhr* or Perſepolis bear ſome reſemblance to the old Runic letters of the Scandinavians. Thoſe inſcriptions we take to have been Parthian; and we hope, as the Parthians were a Tartarian clan, this conjecture may be admitted till another more plausible is diſcovered. The Perſians, it is true, did once more recover the empire; and under them began the reign of the Deri and Parſi tongues; the former conſiſting of the old Perſian and Parthian highly poliſhed; the latter of the ſame languages in their uncultivated vernacular dreſs. In this ſituation the Perſian language remained till the invaſion of the Saracens in 636; when theſe barbarians over-ran and ſettled in that fine country; demolſhed every monument of antiquity, records, temples, palaces; every remain of ancient ſuperſtition; maſſacred or expelled the miniſters of the Magian idolatry; and introduced a language, though not entirely new, yet widely diſſering from the old exemplar.

But before we proceed to give ſome brief account of the modern Perſian, we muſt take the liberty to hazard one conjecture, which perhaps our adepts in modern Perſian may not find themſelves diſpoſed to admit. In modern Perſian we find the ancient Perſian names wonderfully diſtorted and deſtroyed from that form under which they appear in the Scripture, in Cteſias, Megathenes, and the other Greek authors. From this it has been inferred that not only the Greeks, but even the ſacred hiſtorians of the Jews, have changed and metamorphoſed them moſt unmercifully, in order to accommodate them to the ſtandard of their own language. As to the Greeks, we know it was their conſtant practice, but we cannot believe ſo much of the Hebrews. We make no doubt of their writing and pronouncing the names of the Perſian monarchs and governors of that nation nearly in the ſame manner with the native Perſians. It is manifeſt, beyond all poſſibility of contradiction, that they neither altered the Tyrian and Phœnician names of perſons and places when they had occaſion to mention them, nor thoſe of the Egyptians when they occurred in their writings. The Babylonian and Chaldaic names which are mentioned in the Old Teſtament vary nothing from the Chaldean original. No reaſon can be aſſigned why they ſhould have transformed the Perſian names more than the others. On the contrary, in Ezra, Nehemiah, and Eſther, we find the Perſian names faithfully preſerved throughout.

The fact, we imagine, is this: Our modern admirers of the Perſic have borrowed their names of the ancient kings and heroes of that country from romances and fabulous legends of more modern date and compoſition. The archives of Perſia were deſtroyed by the Saracens: nothing of importance was written in that country till two centuries after the era of Mohammed. What ſucceeded was all fiction and romance.

conqueſt.

The

Perſian Language.

The authors of theſe entertaining compositions either forged names of heroes to answer their purpoſe, or laid hold on ſuch as were celebrated in the ballads of their country, or preſerved by vulgar tradition. The names were no doubt very different from thoſe of the ancient kings and heroes of Perſia; and probably many of them had undergone conſiderable changes during the continuance of the Parthian empire. Upon this foundation has the learned Mr Richardſon erected a very irregular, fabric, new, and, to uſe his own expreſſion, we think built upon *pillars of ice*. He has taken much pains to invalidate the credit of the Grecian hiſtories of the Perſian empire, by drawing up in battle array againſt their records legions of romantic writers, who were not born till near a thouſand years after the events had taken place; and to complete the probability, who lived 200 years after all the chronicles of the Medes and Perſians had been finally deſtroyed by the fury of the Saracens.

After the deciſive victory obtained over the Perſians at Kodeſſi, their ancient government was overturned, their religion proſcribed, their laws trampled under foot, and their civil tranſactions diſturbed by the forcible introduction of the lunar for the ſolar calendar; while, at the ſame time, their language became almoſt overwhelmed by an inundation of Arabic words: which from that period, religion, authority, and faſhion, incorporated with their idiom.

From the ſeventh till the tenth century the Perſian tongue, now impregnated with Arabic words, appears to have laboured under much diſcouragement and neglect. Bagdad, built by Almanſor, became ſoon after the year 762 the chief reſidence of the khalifs, and the general reſort of the learned and the ambitious from every quarter of the empire. At length the acceſſion of the Buyah princes to the Perſian throne marked in the tenth century the great epoch of the revival of Perſian learning. About the year 977 the throne of Perſia was filled by the great Azaduddawla; who firſt aſſumed the title of *Sulian*, afterwards generally adopted by eaſtern princes. He was born in Iſpahan, and had a ſtrong attachment to his native kingdom. His court, whether at Bagdad or in the capital of Perſia, was the ſtandard of taſte and the favourite reſidence of genius. The native dialect of the prince was particularly diſtinguiſhed, and became ſoon the general language of compoſition in almoſt every branch of polite learning. From the end of the tenth till the ſiſteenth century may be conſidered as the moſt flouriſhing period of Perſian literature. The epic poet Ferdauſi, in his romantic hiſtory of the Perſian kings and heroes, diſplays an imagination and ſmoothneſs of numbers hardly inferior to Homer. The whole fanciful range of Perſian enchantment he has interwoven in his poems, which abound with the nobleſt efforts of genius. This bard has ſtamped a dignity on the monſters and fi&ions of the eaſt, equal to that which the prince of epic poetry has given to the mythology of ancient Greece. His language may at the ſame time be conſidered as the moſt refined dialect of the ancient Perſian, the Arabic being introduced with a very ſparing hand; whiſt Sadi, Jami, Hafez, and other ſucceeding writers, in proſe as well as verſe, have blended in their works the Arabic without reſerve; gaining perhaps in the nervous luxuriance of the one language

87
The moſt flouriſhing period of Perſian literature.

what may ſeem to have been loſt in the ſofter delicacy of the other. Hence Ebn Fekreddin Anju, in the preface to the Dictionary called *Farhang Jenungi*, ſays, that the Deri and the Arabic idioms were the languages of heaven; God communicating to the angels his milder mandates in the delicate accents of the firſt, whiſt his ſtern commands were delivered in the rapid accents of the laſt.

For near 300 years the literary fire of the Perſians ſeems indeed to have been almoſt extinguished; ſince, during that time, hardly any thing of that people which deſerves attention has appeared in Europe: enough, however, has already been produced, to inſpire us with a very high opinion of the genius of the eaſt. In taſte, the orientals are undoubtedly inferior to the beſt writers of modern Europe; but in invention and ſublimity they are excelled, perhaps equalled, by none. The Perſians aſſect a rhetorical luxuriance, which to a European wears the air of unneceſſary redundancy. If to theſe leading diſtin&ions we add a peculiar tone of imagery, of metaphor, of illuſion, derived from the difference of government, of manners, of temperament, and of ſuch natural objects as characterize Aſia from Europe; we ſhall ſee at one view, the great points of variation between the writers of the eaſt and weſt. Amongſt the oriental hiſtorians, philoſophers, rhetoricians, and poets, many will be found who would do honour to any age or people; whiſt their romances, their tales, and their fables, ſtand upon a ground which Europeans have not yet found powers to reach. We might here quote the Arabian Nights Entertainments, Perſian Tales, Pilpay's Fables, &c.

We ſhall now annex a few ſtri&ures on the genius of that noble language; though it is our opinion that the province of the philologiſt is to investigate the origin, progrefs, and final improvement of a language, without deſcending to its grammatical minutiae or peculiar idiomatic diſtin&ions. We have already obſerved, that the tongue under conſideration is partly Arabic and partly Perſian, though the latter generally has the aſcendant. The former is nervous, impetuous, and maſculine; the latter is flowing, ſoft, and luxuriant. Wherever the Arabic letters do not readily incorporate with the Perſian, they are either changed into others or thrown away. Their letters are the Arabic with little variation; theſe being found more commodious and expeditious than the old letters of the Deri and Perſi. Their alphabet conſiſts of 32 letters, which like the Arabic, are read from right to left; their form and order will be learned from any grammar of that language. The letters are divided into vowels and conſonants as uſual. The Arabic characters, like thoſe of the Europeans; are written in a variety of different hands; but the Perſians write their poetical works in the *Talick*, which answers to the moſt elegant of our Italic hand.

There is a great reſemblance between the Perſian and English languages in the facility and ſimplicity of their form and conſtruction: the former, as well as latter, has no difference of terminations to mark the gender either in ſubſtantives or a&jectives: all inanimate things are neuter; and animals of different ſexes have either different names, or are diſtinguiſhed by the words *nr* male, and *ma* female. Sometimes indeed

deed

deed a word is made feminine, after the manner of the
 Persian Language. Arabians, by having *s* added to it.

The Persian substantives have but one variation of case which is formed by adding a syllable to the nominative in both numbers: and answers often to the dative, but generally to the accusative, case in other languages. The other cases are expressed for the most part by particles placed before the nominative. The Persians have two numbers, singular and plural: the latter is formed by adding a syllable to the former.

The Persian adjectives admit of no variation but in the degrees of comparison. The comparative is formed by adding *ter*, and the superlative by adding *terin* to the positive.

The Persians have active and neuter verbs like other nations; but many of their verbs have both an active and neuter sense, which can be determined only by the construction. Those verbs have properly but one conjugation, and but three changes of tense: the imperative, the aorist, and the preterite; all the other tenses being formed by the help of particles or auxiliary verbs. The passive voice is formed by adding the tenses of the substantive verb to the participle of the active.

In the ancient language of Persia there were very few or no irregularities; the imperative, which is often irregular in the modern Persian was anciently formed from the infinitive, by rejecting the termination *eden*; for originally all infinitives ended in *den*, till the Arabs introduced their harsh consonants before that syllable, which obliged the Persians, who always affected a sweetness of pronunciation, to change the old termination of some verbs into *ten*, and by degrees the original infinitive grew quite obsolete: yet they still retain the ancient imperative, and the aorists which are formed from it. This little irregularity is the only anomalous part of the Persian language; which nevertheless far surpasses in simplicity all other languages ancient or modern.

With respect to the more minute and intricate parts of this language, as well as its derivations, compositions, constructions, &c. we must remit our readers to Minnikie's *Institutiones Linguae Turicae cum rudimentis parallelis linguarum Arab. et Pers.* Sir William Jones's Persian Grammar; Mr Richardson's Arabian and Persian Dictionary; D. Herbelot's *Bibl. Orient.* Dr Hyde de *Relig. vet. Pers.* &c. Our readers, who would penetrate into the innermost recesses of the Persian history, colonies, antiquities, connections, dialects, may consult the last mentioned author, especially chap. xxxv. *De Persia et Persarum nominibus, et de Moderna atque veteri lingua Persica usque dialectis.* In the preceding inquiry we have followed other authors, whose accounts appeared to us more natural, and much less embarrassing.

To conclude this section, which might easily have been extended into a large volume, we shall only take the liberty to put our readers in mind of the vast utility of the Arabian and Persian languages. Numberless events are preserved in the writings of the orientals which were never heard of in Europe, and must have for ever lain concealed from the knowledge of its inhabitants, had not these two tongues been studied and understood by the natives of this quarter of the globe. Many of those events have been transmit-

ted to posterity in poems and legendary tales like the Runic fragments of the north, the romances of Spain, or the Heroic ballads of Great Britain. Such materials as these, we imagine, may have suggested to Firdausi, the celebrated heroic poet of Persia, many of the adventures of his *Shahnamé*: which, like Homer when stripped of the machinery of supernatural beings, is supposed to contain much true history, and a most undoubted picture of the superstition and manners of the times. The knowledge of these two languages has laid open to Europe all the treasures of oriental learning, and has enriched the mind of Britons with Indian science as much as the produce of these regions has increased their wealth and enervated their constitution.

Before we conclude this section, we shall subjoin a few strictures on the nature of Persian poetry, in order to render our inquiry the more complete. The modern Persians borrowed their poetical measures from the Arabs: they are exceedingly various and complicated; they consist of 19 different kinds; but the most common of them are the *Iambic* or *Trochaic* measure, and a metre that chiefly consists of those compounded feet which the ancients called *επιτριταε*, which are composed of iambic and spondees alternately. In lyric poetry their verses generally consist of 12 or 16 syllables; they sometimes, but seldom, consist of 14. Some of their lyric verses contain 13 syllables: but the most common Persian verse is made up of 11; and in this measure are written all their great poems, whether upon heroic or moral subjects, as the works of Firdausi and Jami, the Bostar of Sadi, and the *Mesnavi* of Gelaleddin. This sort of verse answers to our common heroic rhyme, which was brought to so high a degree of perfection by Pope. The study of the Persian poetry is so much the more necessary, as there are few books or even letters written in that language, which are not interspersed with fragments of poetry. As to their prosody, nothing can be more easy and simple. When the student can read prose easily, he will with a little attention read poetry with equal facility.

SECT. V. *Shanferit and Bengalse Languages.*

THE Shanferit, though one of the most ancient languages in the world, was little known even in Asia till about the middle of the present century. Since that period, by the indefatigable industry of the very learned and ingenious Sir William Jones and the other worthy members of that society of which he has the honour to be president, that noble and ancient language has at length been brought to light; and from it vast treasures of oriental knowledge will be communicated both to Europe and Asia; knowledge which, without the exertions of that establishment, must have lain concealed from the researches of mankind to the end of the world. In this section we propose to give to our readers such an account of that language as the limits of the present article, and the helps we have been able to procure, shall permit.

The Shanferit language has for many centuries lain concealed in the hands of the bramins of Hindostan. It is by them deemed sacred, and is of consequence confined solely to the offices of religion. Its name imports

⁹⁰ Utility of the Arabian and Persian languages.

Persian Language.

⁹¹ Persian Poetry.

⁹² The Shanferit one of the most ancient languages in the world.

Shanferit imports the *perfect language*, or, according to the eastern style, *the language of perfection*; and we believe no language ever spoken by man is more justly intitled to that high epithet.

93
Traces of Shanferit in every district of Asia and elsewhere.

The grand source of Indian literature, and the parent of almost every dialect from the Persian gulph to the China seas, is the Shanferit; a language of the most venerable and most remote antiquity, which, tho' at present shut up in the libraries of the bramins, and appropriated solely to the records of their religion, appears to have been current over most of the oriental world. Accordingly traces of its original extent may be discovered in almost every district of Asia. Those who are acquainted with that language have often found the similitude of Shanferit words to those of Persian and Arabic, and even of Latin and Greek; and that not in technical and metaphorical terms, which refined arts and improved manners might have occasionally introduced, but in the main ground-work of language, in monosyllables, the names of numbers, and appellations of such things as would be first discriminated on the immediate dawn of civilization.

The ancient coins of many different and distant kingdoms of Asia are stamped with Shanferit characters, and mostly contain allusions to the old Shanferit mythology. Besides, in the names of persons and places, of titles and dignities, which are open to general notice, even to the furthest limits of Asia, may be found manifest traces of the Shanferit. The scanty remains of coptic antiquities afford little scope for comparison between that idiom and this primitive tongue; but there still exists sufficient ground to conjecture, that, at a very early period, a correspondence did subsist between these two nations. The Hindoos pretend, that the Egyptians frequented their country as disciples, not as instructors; that they came to seek that liberal education and those sciences in Hindostan, which none of their own countrymen had sufficient knowledge to impart. Perhaps we may examine the validity of this claim hereafter.

94
Number of books in that language.

But though numberless changes and revolutions have from time to time convulsed Hindostan, that part of it which lies between the Indus and the Ganges still preserves that language whole and inviolate. Here they still offer a thousand books to the perusal of the curious; many of which have been religiously handed down from the earliest periods of human existence.

95
Characteristics of it.

The fundamental part of the Shanferit language is divided into three classes: *Dhaat*, or roots of verbs, which some call primitive elements; *Shubh*, or original nouns; and *Eva*, or particles. The latter are ever indeclinable, as in other languages; but the words comprehended in the two former classes must be prepared by certain additions and inflexions to fit them for a place in composition. And here it is that the art of the grammarian has found room to expand itself, and to employ all the powers of refinement. Not a syllable, not a letter, can be added or altered but by regimen; not the most trifling variation of the sense, in the minutest subdivision of declension or conjugation, can be effected without the application of several rules: all the different forms for every change of gender, number, case, person, tense, mood, or degree, are methodically arranged for the assistance of the me-

emory, according to an unerring scale. The number of the radical or elementary parts is about 700; and to these, as to the verbs of other languages, a very plentiful stock of verbal nouns owes its origin; but these are not thought to exceed those of the Greek either in quantity or variety.

Shanferit and Bengalese Languages.

To the triple source of words mentioned above, every term of truly Indian origin may be traced by a laborious and critical analysis. All such terms as are thoroughly proved to bear no relation to any one of the Shanferit roots, are considered as the production of some remote and foreign idiom, subsequently ingrafted upon the main stock; and it is conjectured, that a judicious investigation of this principle would throw a new light upon the first invention of many arts and sciences, and open a fresh mine of philological discoveries. We shall now proceed to give as exact an account of the constituent parts of this language as the nature of our design will permit.

96
It is copious and nervous.

The Shanferit language is very copious and nervous. The first of these qualities arises in a great measure from the vast number of compound words with which it is almost overstocked. "The Shanferit (says Sir William Jones), like the Greek, Persian, and German, delights in compounds; but to a much higher degree, and indeed to such excess, that I could produce words of more than 20 syllables; not formed ludicrously like that by which the buffoon in Aristophanes describes a feast, but with perfect seriousness, on the most solemn occasions, and in the most elegant works." But the style of its best authors is wonderfully concise. In the regularity of its etymology it far exceeds the Greek and Arabic; and, like them, has a prodigious number of derivatives from each primary root. The grammatical rules also are numerous and difficult, though there are not many anomalies. As one instance of the truth of this assertion, it may be observed, that there are seven declensions of nouns, all used in the singular, the dual, and the plural numbers, and all of them differently formed, according as they terminate with a consonant, with a long or a short vowel; and again, different also as they are of different genders: not a nominative case can be formed to any one of these nouns without the application of at least four rules, which vary likewise with each particular difference of the nouns, as above stated: add to this, that every word in the language may be used through all the seven declensions, which is a full proof of the difficulty of the idiom.

The Shanferit grammars are called *Braakoon*, of which there are many composed by different authors: some too abstruse even for the comprehension of most bramins, and others too polix to be ever used but as references. One of the shortest, named the *Sarajostee*, contains between two and three hundred pages, and was compiled by Anobhōōtēē Seroopēnām Achārige, with a conciseness that can scarcely be paralleled in any other language.

97
Shanferit

The Shanferit alphabet contains 50 letters; and it is one boast of the bramins, that it exceeds all other alphabets in this respect: but it must be observed, that as of their 34 consonants, near half carry combined sounds, and that six of their vowels are merely the correspondent long ones to as many which are short, the advan-

Shanferit
and Benga-
lese Lan-
guages.

tage seems to be little more than fanciful. Besides these, they have a number of characters which Mr Hallid calls connected vowels, but which have not been explained by the learned president of the Asiatic Society.

* Plate
CCCXC.

The Shanferit character used in Upper Hindostan * is said to be the same original letter that was first delivered to the people by Brahma, and is now called *Dicwanāgar*, or the language of angels, which shows the high opinion that the bramins have entertained of that character. Their consonants and vowels are wonderfully, perhaps whimsically, modified and diversified; to enumerate which, in this place, would contribute very little either to the entertainment or instruction of our readers. All these distinctions are marked in the *Beids* (L), and must be modulated accordingly; so that they produce all the effect of a laboured recitative: but by an attention to the music of the chant, the sense of the passage recited equally escapes the reader and the audience. It is remarkable, that the Jews in their synagogues chant the Pentateuch in the same kind of melody; and it is supposed that this usage has descended to them from the remotest ages.

93
Poetry.

The Shanferit poetry comprehends a very great variety of different metres, of which the most common are these:

The *munnee kurreneh chhund*, or line of 12 or 19 syllables, which is scanned by three syllables in a foot, and the most approved foot is the anapaest.

The *cātee chhund*, or line of 11 syllables.

The *anūshṭose chhund*, or line of eight syllables.

The poems are generally composed in stanzas of four lines, called *ashlogues*, which are regular or irregular.

The most common ashlogue is that of the *anūshṭose chhund*, or regular stanza of eight syllables in each line. In this measure the greatest part of the *Māhābāret* is composed. The rhyme in this kind of stanza should be alternate; but the poets do not seem to be very nice in the observance of a strict correspondence in the sounds of the terminating syllables, provided the feet of the verse are accurately kept.

This short *anūshṭose ashlogue* is generally written by two verses in one line, with a pause between; so the whole then assumes the form of a long distich.

The irregular stanza is constantly called *anyāchhund*, of whatever kind of irregularity it may happen to consist. It is most commonly compounded of the long line *cātee chhund* and the short *anūshṭose chhund* alternately; in which form it bears some resemblance to the most common lyric measure of the English.

To pursue this subject to greater length is scarce possible for us, as matters stand at present. Our readers must suspend their curiosity till more volumes of the *Asiatic Researches* are published, where we make no doubt the whole mystery of this extraordinary language will be plainly unfolded.

Perhaps our readers may feel a curiosity to be informed of the origin of this oriental tongue. If we believe the bramins themselves, it was coeval with the race of man, as was observed towards the beginning of

this secton. The bramins, however, are not the only people who ascribe a kind of eternity to their own particular dialect. We find that the Shanferit in its primitive destination was appropriated to the offices of religion. It is indeed pretended, that all the other dialects spoken in Hindostan were emanations from that fountain, to which they might be traced back by a skilful etymologist. This, we think, is an argument of no great consequence, since we believe that all the languages of Europe, by the same process, may be deduced from any one of these current in that quarter of the globe. By a parity of reason, all the different dialects of Hindostan may be referred to the language in question. Indeed, if we admit the authority of the Mosaic history, all languages whatsoever are derived from that of the first man. It is allowed that the language under consideration is impregnated with Persian, Chaldaic, Phœnician, Greek, and even Latin idioms. This, we think, affords a presumption that the Shanferit was one of those original dialects which were gradually produced among the descendants of Noah, in proportion as they gradually receded from the centre of population. What branch or branches of that family emigrated to Hindostan, it is not easy to determine. That they were a party of the descendants of Shem is most probable, because the other sects of his posterity settled in that neighbourhood. The sum then is, that the Hindoos were a colony consisting of the descendants of the patriarch Shem.

It appears, however, by almost numberless monuments of antiquity still existing, that at a very early period a different race of men had obtained settlements in that country. It is now generally admitted, that colonies of Egyptians had peopled a considerable part of Hindostan. Numberless traces of their religion occur everywhere in those regions. The very learned president himself is positive, that vestiges of those sacerdotal wanderers are found in India, China, Japan, Tibet, and many parts of Tartary. Those colonists, it is well known, were zealous in propagating their religious ceremonies wherever they resided, and wherever they travelled. There is at the same time even at this day a striking resemblance between the sacred rites of the vulgar Hindoos and those of the ancient Egyptians. The prodigious statues of Salfette and Elephanta fabricated in the Egyptian style; the vast excavations hewn out of the rock in the former; the woolly hair of the statues, their distorted attitudes, their grotesque appearances, their triple heads, and various other configurations—plainly indicate a foreign original. These phenomena suit no other people on earth so exactly as the sons of Mizraim. The Egyptian priests used a sacred character, which none knew but themselves; none were allowed to learn except their children and the choice of the initiated. All these features mark an exact parallel with the bramins of the Hindoos. Add to this, that the dress, diet, lustrations, and other rites of both sects, bore an exact resemblance to each other. Sir William Jones hath justly observed, that the letters of the Shanferit, strip of all adventitious appendages, are really the square Chaldaic cha-

Origin of
Shanferit.

(L) The books which contain the religion of the bramins.

Shanferit and Bengalese Languages. characters. We learn from Cassiodorus* the following particulars: "The height of the obeliks is equal to that of the circus; now the higher is dedicated to the sun, and the lower to the moon, where the sacred rites of the ancients are intimated by Chaldaic signatures by way of letters." Here then it is plain that the sacred letters of the Egyptians were Chaldaic, and it is allowed that those of the bramins were of the same complexion; which affords a new presumption of the identity of the Shanferit with those just mentioned.

* Lib. iii. epist. 2. ct. 51.

That the Egyptians had at a very early period penetrated into Hindostan, is universally admitted. Olliris, their celebrated monarch and deity, according to their mythology, conducted an army into that country; taught the natives agriculture, laws, religion, and the culture of the vine, &c. He is said at the same time to have left colonies of priests, as a kind of missionaries, to instruct the people in the ceremonies of religion. Sesostris, another Egyptian potentate, likewise over-ran Hindostan with an army, and taught the natives many useful arts and sciences. When the pastor-kings invaded and conquered Egypt, it is probable that numbers of the priests, in order to avoid the fury of the merciless invaders who demolished the temples and persecuted the ministers of religion, left their native country, and transported themselves into India. These, we should think, were the authors both of the language and religion of the bramins. This dialect, as imported by the Egyptians, was probably of the same texture with the sacred language of that people, as it appeared many ages after. The Indians, who have always been an inventive and industrious race of men, in process of time cultivated, improved, diversified, and constructed that language with such care and assiduity, that it gradually arrived at that high degree of perfection in which at present it appears.

Had the learned president of the Asiatic Society (M) when he instituted a comparison between the deities of Hindostan on the one side and of Greece and Italy on the other, examined the analogy between the gods of Hindostan and those of Egypt, we think he would have performed a piece of service still more eminent. Having first demonstrated the similarity between the divinities of India and Egypt, he might then have proceeded to investigate the resemblance of the Egyptian and Phœnician with those of Greece and Rome. By this process a chain would have been formed which would have conducted his reader to comprehend at one view the identity of the Zabian worship almost throughout the world.

We foresee that it will be objected to this hypothesis, that all the dialects of Hindostan being clearly reducible to the Shanferit, it is altogether impossible that it could have been a foreign language. To this we answer, that at the early period when this event is supposed to have taken place, the language of the posterity of the sons of Noah had not deviated considerably from the primitive standard, and consequently the language of the Egyptians and the Hindoos was nearly

the same. The Shanferit was gradually improved: the language of the vulgar, as is always the case, became more and more different from the original archetype; but still retained such a near resemblance to the mother-tongue as proved the verity of its extraction.

Shanferit and Bengalese Languages.

To the preceding account of the Shanferit language we shall annex a few strictures on the language of Bengal, which we believe is derived from the other, and is in most common use in the southern parts of Hindostan.

Bengal language deriv'd from the Shanferit.

Though most of the ancient oriental tongues are read from right to left, like the Hebrew, Chaldaic, Arabic, &c. yet such as properly belong to the whole continent of India proceed from left to right like those of Europe. The Arabic, Persian, &c. are the grand sources whence the former method has been derived; but with these, the numerous original dialects of Hindostan have not the smallest connection or resemblance.

The great number of letters, the complex mode of combination, and the difficulty of pronunciation, are considerable impediments to the study of the Bengal language; and the carelessness and ignorance of the people, and the inaccuracy of their characters, aggravate these inconveniencies. Many of their characters are spurious; and these, by long use and the hurry of business, are now almost naturalized into the language.

The Bengal alphabet, like that of the Shanferit, from which it is derived, consists of 50 letters, whose form, order, and sound, may be learned from Mr Halded's grammar of the Bengal language. The vowels are divided into long and short, the latter of which are often omitted in writing. Most of the oriental languages are constructed upon the same principle, with respect to the omission of the short vowels. The Hebrews had no sign to express it before the invention of the Masoretic points; in Arabic it is rarely inserted unless upon very solemn occasions, as in the Koran; in the modern Persian it is universally omitted: so to all the consonants in the Shanferit, the short vowel is an invariable appendage, and is never signified by any diaeretical mark; but where the construction requires that the vowel should be dropped, a particular stroke is set under the letter. It is in vain to pretend, in a sketch like this, to detail the sound and pronunciation of these letters: this must be acquired by the ear and by practice.

101 Bengal alphabet.

In the Bengal language there are three genders, as in Greek, Arabic, &c. The authors of this threefold division of genders, with respect to their precedence, appear to have considered the neuter as a kind of residuum resulting from the two others, and as less worthy or less comprehensive than either (see Section of the *Greek*). The terminations usually applied upon this occasion are *aa* for the masculine, and *ee* for the feminine. In Shanferit as in Greek and Latin, the names of all things inanimate have different genders, founded on vague and incomprehensible distinctions: the same is the case with the Bengal.

102 Genders, &c. of this language.

103
Peculiarities
of
Shanferit
and Benga-
lese nouns.

A Shanferit noun, on its first formation from its general root, exists equally independent of case as of gender. It is neither nominative, nor genitive, nor accusative; nor is impressed with any of those modifications which mark the relation and connection between the several members of a sentence. In this state it is called an *imperfect* or *crude* noun. To make a nominative of a word, the termination must be changed and a new form supplied. Thus we see, that in the Shanferit, at least the nominative has an equal right with any other inflexion to be called a case. Every Shanferit noun has seven cases, exclusive of the vocative; and therefore comprehends two more than even those of the Latin. Mr Halhed above mentioned details all the varieties of those with great accuracy, to whose Grammar we must refer our readers. The Bengal has only four cases besides the vocative: in which respect it is much inferior to the other.

It would be difficult to account for the variety of words which have been allotted to the class of pronouns by European grammarians. The first and second person are chiefly worthy of observation: these two should seem to be confined to rational and conversable beings only: the third supplies the place of every object in nature; wherefore it must necessarily be endued with a capacity of shifting its gender respectively as it shifts the subject; and hence it is in Shanferit frequently denominated an adjective. One of the demonstratives *hic* or *ille* usually serves for this purpose; and generally the latter, which in Arabic has no other name than *abmeer le ghaayb*, "the pronoun of the absentee," for whose name it is a substitute.

104
Bengalese
pronouns.

In most languages where the verb has a separate inflection for each person, that inflection is sufficient to ascertain the personality; but in Bengal compositions, though the first and second persons occur very frequently, nothing is more rare than the usage of the pronoun of the third; and names of persons are inserted with a constant and disgusting repetition, to avoid, as it should seem, the application of the words *HE* and *SHE*. The second person is always ranked before the first, and the third before the second. The personal pronouns have seven cases, which are varied in a very irregular manner. Leaving these to the Bengalian grammar, we shall proceed to the *verb*.

The Shanferit, the Arabic, the Greek and Latin verbs, are furnished with a set of inflections and terminations so comprehensive and so complete, that by their form alone they can express all the different distinctions both of persons and time. These separate qualities in them are perfectly blended and united. Thus by their root they denote a particular act, and by their inflexion both point out the time when it takes place and the number of the agents. In Persian, as in English, the verb admits but of two forms, one for the present tense and one for the aorist; and it is observable, that while the past tense is provided for by a peculiar inflexion, the future is generally supplied by an additional word conveying only the idea of time, without any other influence on the act implied by the principal verb. It is also frequently necessary that the different state of the action, as perfect or imperfect, be further ascertained in each of the tenses, past, present, and future. This also, in the learned

languages, is performed by other variations or inflections, for which other verbs and other particles are applied in the modern tongues of Europe and Persia.

Every Shanferit verb has a form equivalent to the middle voice of the Greek, used through all the tenses with a reflexive sense, and the former is even the most extensive of the two in its use and office; for in Greek the reflexive can only be adopted intransitively when the action of the verb descends to no extraneous subject; but in Shanferit, the verb is both reciprocal and transitive at the same time.

Neither the Shanferit, nor the Bengalese, nor the Hindostanic, have any word precisely answering to the sense of the verb *I have*, and consequently the idea is always expressed by *est mihi*; and of course there is no auxillary form in the Bengal verb correspondent to *I have written*, but the sense is conveyed by another mode. The verb substantive, in all languages, is defective and irregular, and therefore the Shanferit calls it a *jeni-verb*. It is curious to observe that the present tense of this verb, both in Greek and Latin, and also in the Persian, appears plainly to be derived from the Shanferit. In the Bengalese, this verb has but two distinctions of time, the present and the past; the terminations of the several persons of which serve as a model for those of the same tense in all other verbs respectively.

Verbs of the Bengal language may be divided into three classes, which are distinguished by their penultimate letter. The simple and most common form has an open consonant immediately preceding the final letter of the infinitive. The second is composed of those words whose final letter is preceded by another vowel or open consonant going before it. The third consists entirely of causals derived from verbs of the first and second conjugations. The reader will easily guess at the impossibility of prosecuting this subject to any greater length: we shall therefore conclude with a few remarks collected from the grammar so often mentioned, which we apprehend may be more amusing, if not more instructing.

The Greek verbs in *μ* are formed exactly upon the same principle with the Shanferit conjugations, even in the minutest particulars. Instances of this are produced in many verbs, which from a root form a new verb by adding the syllable *mi*, and doubling the first consonant. This mode furnishes another presumption of the Egyptian origin of the Shanferit. Many Greeks travelled into Egypt: many Egyptian colonies settled in Greece. By one or other of those channels the foregoing innovation might have been introduced into the Greek language.

To form the past tense, the Shanferit applies a syllabic augment, as is done in the Greek: the future has for its characteristic a letter analogous to that of the same tense in the Greek, and it omits the reduplication of the first consonant. It may be added, that the reduplication of the first consonant is not constantly applied to the present tense of the Shanferit more than to those of the Greek.

The natural simplicity and elegance of many of the Asiatic languages are greatly debased and corrupted by the continual abuse of auxiliary verbs; and this inconvenience has evidently affected the Persian, the Hindostan, and the Bengal idioms.

Shanſcrit and Bengaleſe Language. The infinitives of verbs in the Shanſcrit and Bengaleſe are always uſed as ſubſtantive nouns. Every body knows that the ſame mode of arrangement very often occurs in the Greek.

In the Shanſcrit language, as in the Greek, there are forms of infinitives and of particles comprehensive of time; there are alſo other branches of the verb that ſeem to reſemble the gerunds and ſupines of the Latin.

All the terms which ſerve to qualify, to diſtinguiſh, or to augment, either *ſubſtance* or *action*, are claſſed by the Shanſcrit grammarians under one head; and the word uſed to expreſs it literally ſignifies *increase* or *addition*. According to their arrangement, a ſimple ſentence conſiſts of three members; the *agent*, the *action*, the *ſubject*: which, in a grammatrical ſenſe, are reduced to two; the *noun* and the *verb*. They have a particular word to ſpecify ſuch words as amplify the noun which imports quality, and answers to our *adjectives* or *epithets*: Such as are applied to denote relation or connection, are intimated by another term which we may tranſlate *prepoſition*.

107 Shanſcrit and Bengaleſe adjectives. The adjectives in Bengaleſe have no diſtinction of gender or number; but in Shanſcrit theſe words preſerve the diſtinction of gender, as in the Greek and Latin.

Prepoſitions are ſubſtitutes for caſes, which could not have been extended to the number neceſſary for expreſſing all the ſeveral relations and predicaments in which a noun may be found, without cauſing too much embarraſſment in the form of a declenſion. Thoſe are too few in the Greek language, which occaſions much inconvenience. See ſect. *Greek*.

The Latin is leſs poliſhed than the Greek, and of conſequence bears a much nearer reſemblance to the Shanſcrit, both in words, inflections, and terminations.

The learned are now convinced that the uſe of numerical figures was firſt derived from India. Indeed the antiquity of their application in that country far exceeds the powers of investigation. All the numerals in Shanſcrit have different forms for the different genders, as in Arabic. There appears a ſtrong probability that the European method of computation was derived from India, as it is much the ſame with the Shanſcrit, though we think the Europeans learned it from the Arabians. The Bengaleſe merchants compute the largeſt ſums by *fours*; a cuſtom evidently derived from the original mode of computing by the fingers.

The Shanſcrit language, among other advantages, has a great variety in the mode of arrangement; and the words are ſo knit and compacted together, that every ſentence appears like one complete word. When two or more words come together in *regimine*, the laſt of them only has the termination of a caſe; the others are known by their poſition; and the whole ſentence ſo connected, forms but one compound word, which is called a *foot*.

SECT. VI. *Of the Chineſe Language.*

108 Antiquity of the Chineſe. THE Chineſe, according to the moſt authentic accounts, are a people of great antiquity. Their ſituation was ſuch, as, in the earlieſt ages of the world,

in a great meaſure ſecured them from hoſtile invaſion. Their little commerce with the reſt of mankind precluded them the knowledge of thoſe improvements which a mutual emulation had often generated among other nations, who were ſituated in ſuch a manner, with relation to each other, as ſerved to promote a mutual intercourſe and correſpondence. As China is a large and fertile country, producing all the neceſſaries, conveniencies, and even the luxuries of life, its inhabitants were not under the neceſſity of looking abroad for the two former, nor expoſed to the temptation of engaging in foreign commerce, in order to procure the latter. Perfectly ſatiſhed with the articles which their own country produced, they applied themſelves entirely to the practice of agriculture and other arts connected with that profeſſion; and their frugality, which they retain even to this day, taught them the leſſon of being contented with little: of conſequence, though their population was almoſt incredible, the produce of their ſoil was abundantly ſufficient to yield them a ſubſiſtence. Their inventions were their own; and as they borrowed nothing from other people, they gradually began to deſpiſe the reſt of mankind, and, like the ancient Egyptians, branded them with the epithet of *barbarians*.

Thoſe people had at an early period made amazing proficiency in the mechanical arts. Their progreſs in the liberal ſciences, according to the lateſt and indeed the moſt probable accounts, was by no means proportioned. In mathematics, geometry, and aſtronomy, their knowledge was contemptible; and in ethics, or moral philoſophy, the complexion of their laws and cuſtoms proves their ſkill to have been truly ſuperficial. They value themſelves very highly at preſent upon their oratorical talents; and yet of all languages ſpoken by any civilized people, theirs is confeſſedly the leaſt improved. To what this untowardly defect is owing, the learned have not yet been able to determine.

109 Their language as original tongue. The language of the Chineſe is totally different from thoſe of all other nations, and bears very ſtrong ſignatures of an original tongue. All its words are monosyllabic, and compoſitions and derivations are altogether unknown. Their nouns and verbs admit of no flexions: in ſhort, every thing relating to their idioms is peculiar, and incapable of being compared with any other dialect ſpoken by any civilized people. Moſt barbarous languages exhibit ſomething that reſembles an attempt towards thoſe diacritical modifications of ſpeech; whereas the Chineſe, after a ſpace of 4000 years, have not advanced one ſtep beyond the very firſt elements of ideal communication. This circumſtance, we think, is a plain demonſtration that they did not emigrate from that region where the primitive race of mankind is thought to have fixed its reſidence. Some have imagined, we believe with good reaſon, that they are a *Tartarian* race, which, breaking off from the main body of that numerous and widely extended people, directed their march towards the ſouth-eaſt. There, falling in with delightful and fertile plains which their poſterity now inhabit, they found themſelves accommodated ſo much to their liking, that they dropped all deſire of changing their habitations. The country of China is, indeed, ſo environed with mountains, deſerts, and ſeas, that

Chinese
Language.

it would have been difficult for men in their primitive state to have emigrated into any of the neighbouring regions. Thus secluded from the rest of mankind, the Chinese, in all probability, were left to the strength of their own inventive powers to fabricate a language, as well as the other arts and improvements necessary for the support and convenience of life.

It is indeed obvious that their stock of vocables, when they emigrated from Tartary, was neither ample nor properly accommodated to answer the purposes of the mutual conveyance of ideas. With this slender stock, however, they seem to have been satisfied; for it does not appear that any additions were afterwards made to that which was originally imported. Instead of framing a new race of terms by compounding their primitive ones; instead of diversifying them by inflections, or multiplying them by derivatives, as is done in every other language; they rather chose to retain their primitive words, and by a variety of modifications, introduced upon their orthography or pronunciation, to accommodate them to a variety of significations. Were it possible to scrutinize all the Tartarian dialects, and to reduce them to their primitive monosyllabic character, perhaps the original language of the Chinese might be investigated and ascertained. We know that attempts have been made to compare it with some of the other Asiatic languages, especially the *Hebrew*: This labour has, however, proved unsuccessful, and no primeval identity has been discovered. Before this comparison could be instituted with the most distant prospect of success, the language last mentioned must be stripped of all its adventitious qualities; and not only so, but it must be reduced to the monosyllabic tone, and then contrasted with the Chinese monosyllables; an undertaking which we are persuaded would not be readily executed. After all, we are convinced that no resemblance of any importance would be discovered.

110
Process of
its fabrica-
tion.

The Chinese language must then, in our opinion, have been a Tartarian dialect, as the people themselves were colonists from Tartary. We have observed above, that those people have not hitherto found out the art of composition of words. This is the more surprising, when we consider that, in the characters which form their written language, they employ many compositions. For example, the character by which they represent *misfortune*, is composed of one hieroglyphic which represents a *house*, and another which denotes *fire*; because the greatest misfortune that can befall a man is to have his house on fire. With respect to the language which they use in speech, though they very often employ many words to express one thing, yet they never run them together into one word, making certain changes upon them that they may incorporate the more conveniently, but always preserve them entire and unaltered.

111
Paucity of
its words

The whole number of words in the Chinese language does not exceed 1200; the nouns are but 326. It must certainly appear surprising, that a people whose

manners are so highly polished and refined, should be able to express so many things as must of necessity attend such a course of life by so small a number of words, and those too monosyllables. The difficulties which attend this singular mode must be felt almost every instant; circumstances which, according to the ordinary course of things, should have induced them to attempt both an augmentation of the number of their words and an extension of those which they had by composition and derivation. We learn from Du Halde* that the Chinese have two different dialects: * *Hist. of China*, vol. ii. the one vulgar, which is spoken by the vulgar, and varies according to the different provinces; the other is called the *Mandarin language*, and is current only among the learned. The latter is properly that which was formerly spoken at court in the province of *Kiang-nan*, and gradually spread among the polite people in the other provinces. Accordingly, this language is spoken with more elegance in the provinces adjoining to *Kiang-nan* than in any other part of the kingdom. By slow degrees it was introduced into all parts of the empire, and consequently became the universal language.

It then appears that the modern language of China was originally the court dialect, and utterly unknown to the bulk of the people. From this circumstance we think it may fairly be concluded that this dialect was deemed the royal tongue, and had been fabricated on purpose to distinguish it from the vulgar dialects. We learn from Heliodorus, that the *Ethiops* had a royal language which was the same with the sacred idiom of the Egyptians. This Mandarin tongue was originally an artificial dialect fabricated with a view to enhance the majesty of the court, and to raise its very style and diction above that of the rest of mankind. The Chinese, a wonderfully inventive people, might actually contrive a language of that complexion, with an intention to render it obscure and enigmatical (s). Such a plan would excite their admiration, and would at the same time greatly exceed their comprehension. In process of time, when the Chinese empire was extended, the Mandarins who had been brought up at court, and understood nothing of the provincial dialects, found it convenient to have the most eminent persons in every province taught the language employed by themselves, in order to qualify them for transacting the affairs of government with them in a language which both understood. By this means the royal dialect descended to the vulgar, and in process of time became universal. The Tartar dialect formerly in use vanished; only a few vestiges of it remained; which gradually incorporating with the royal language, occasioned the variation of provincial tongues abovementioned.

We are therefore clearly of opinion, that the modern language of the Chinese was deduced from the original Mandarin, or court dialect, and that this last was an artificial speech fabricated by the skill and ingenuity of that wonderful people. The learned have long held it up as the primary dialect, because, say they, it bears

(s) An attempt of this nature, among a people like the Chinese, is by no means improbable; nor is it success less probable. For a proof of this, we need only have recourse to Bishop Wilkins's *Artificial Language*, and Pfsalmanazar's *Dictionary of the language of Formosa*.

Chinese Language. bears all the signatures of an original unimproved language. In our opinion, nothing appears more ingeniously artificial. It is universally allowed that, in its structure, arrangement, idioms, and phraseology, it resembles no other language. Is not every learned man now convinced that all the Asiatic languages yet known, discover unequivocal symptoms of their cognation and family resemblance? The Ethiopians, Chaldeans, Arabians, Persians, Egyptians, Hebrews, Phœnicians, the Brahmans, Bengalese, the Hindoos bordering upon China, all speak only different dialects of one language, varying from the original in dialect only, some in a greater some in a lesser degree: why should the Chinese alone stand altogether insulated and unallied?

The languages of the North all wear congenial features. The Tartar, or Tatar dialects of every clan, or every canton, of every denomination, exhibit the most palpable proofs of a near affinity: the Gothic and Slavonian dialects, which pervade a great part of Europe and some parts of Asia, are obviously brethren, and may easily be traced up to an Asiatic original. Even some of the American jargon dialects contain vocables which indicate an Asiatic or European original. Our readers, we flatter ourselves, will agree with us, that had the language of the Chinese been the original language, a resemblance must have still existed between it and its descendants. If it had originated from any other language, it would have retained some characteristic features of its parent archetype. As neither of these are to be found in the fabric of the language under consideration, the conclusion must be, that it is a language entirely different from all other tongues; that it is constructed upon different principles, descended from different parents, and framed by different artists.

The Chinese themselves have a common and immemorial tradition, that their language was framed by *Tao* their first emperor, to whom they attribute the invention of every thing curious, useful, and ornamental. Traditional history, when it is ancient, uniform, and universal, is generally well founded: upon this occasion we think the tradition above mentioned may be fairly admitted as a collateral evidence.

112
A proof of its artificial structure.

The paucity of vocables contained in this singular language, we think another presumption of its artificial texture. The Chinese *Onomatopœia* would find it an arduous task to devise a great number of new terms, and would therefore rest satisfied with the smallest number possible. In other languages we find the like economy was observed. Rather than fabricate new words, men chose sometimes to adapt old words to new, and, upon some occasions, even to contrary significations. To spare themselves the trouble of coining new terms, they contrived to join several old ones into one; whence arose a numerous race of compounds. Derivatives too were fabricated to answer the same purpose. By this process, instead of creating new vocables, old ones were compounded, diversified, deflected, ramified, metamorphosed, and tortured into a thousand different shapes.

The Greek is deservedly esteemed a rich and copious language; its radical words have been curiously traced by several learned men, who, after the most laborious and exact scrutiny, have found that they do not amount

to more than 300. The Shanferit language is highly compounded; its radical terms, however, are very few in number. Upon the whole, we think we may conclude, that the more any language abounds in compounds and derivatives, the smaller will be the number of its radical terms. The Arabic admits of no composition, and of consequence, its words have been multiplied almost *in infinitum*; the Shanferit, the Persian, and the Greek, abound with compounds, and we find their radicals are few in proportion.

Chinese Language.

There are, we think, three different methods which may be employed in order to enrich and extend the range of a language. 1st, By fabricating a multitude of words; the plan which has been pursued by the Arabs. 2d, By framing a multitude of compounds and derivatives; the artifice employed by the Greeks and the authors of the Shanferit. 3d, By varying the signification of words without enlarging their number; the method practised by the Chinese and their colonists. The Arabians, we think, have shown the most fertile and inventive genius, since they have enriched their language by actually creating a new and a most numerous race of words. The fabricators of the Shanferit and the collectors of the Greek have exhibited art, but comparatively little fertility of genius. Leaving, therefore, the Arabians, as in justice we ought, masters of the field in the contest relating to the formation of language, we may range the Greek and Shanferit on the one side, and the Chinese on the other; and having made this arrangement, we may attempt to discover on which side the largest proportion of genius and invention seems to rest.

113
Three different methods of enriching a language.

The Greek and Shanferit (for we have selected them as most highly compounded) exhibit a great deal of art in modifying, arranging, and diversifying their compounds and derivatives, in such a manner as to qualify them for intimating complex ideas; but the Chinese have performed the same office by the help of a race of monosyllabic notes, simple, inflexible, invariable, and at the same time few in number. The question then comes to be, whether more art is displayed in new modelling old words by means of declensions, conjugations, compounds, and derivatives; or by devising a plan according to which monosyllabic radical terms, absolutely invariable, should, by a particular modification of sound, answer all the purposes performed by the other. The latter appears to us much more ingeniously artificial. The former resembles a complicated machine composed of a vast number of parts, congenial indeed, but loosely connected; the latter may be compared to a simple, uniform engine, easily managed, and all its parts properly adjusted. Let us now see in what manner the people in question managed their monosyllabic notes, so as to qualify them for answering all the purposes of speech.

114
That adopted by the Chinese.

Though the number of words in the Chinese language does not amount to above 1200: yet that small number of vocables, by their artificial management, is sufficient to enable them to express themselves with ease and perspicuity upon every subject. Without multiplying words, the sense is varied almost *in infinitum* by the variety of the accents, inflections, tones, aspirations, and other changes of the voice and enunciation; circumstances which make those who do not thoroughly

Chinese Language. thoroughly understand the language frequently mistake one word for another. This will appear obvious by an example.

The word *too* pronounced slowly, drawing out the *v* and raising the voice, signifies a *lord* or *master*. If it is pronounced with an even tone, lengthening the *v*, it signifies a *boy*. When it is pronounced quick and lightly, it imports a *kitchen*. If it be pronounced in a strong and masculine tone, growing weaker towards the end, it signifies a *column*.

By the same economy, the syllable *po*, according to the various accents, and the different modes of pronunciation, has eleven different significations. It signifies *gliss to boil, to winnow rice, wise or liberal, to prepare, an old woman, to break or cleave, inclined, a very little, to water, a slave or captive*. From these examples, and from almost numberless others which might be adduced, it is abundantly evident that this language, which at first sight appears so poor and confined, in consequence of the small number of the monosyllables of which it is composed, is notwithstanding very copious, rich, and expressive.

Again, the same word joined to various others, imports a great many different things; for example *mou*, when alone, signifies a *tree, wood*; but when joined with another word, it has many other significations. *Mou loo*, imports "wood prepared for building;" *mou lin*, is "bars, or wooden grates;" *mou hia*, "a box;" *mou sang*, "a chest of drawers;" *mou tsiang*, "a carpenter;" *mou eul*, "a mullroom;" *mou nu*, "a sort of small orange;" *mou sung*, "the planet Jupiter;" *mou mien*, "cotton," &c. This word may be joined to several others, and has as many different significations as it has different combinations.

Thus the Chinese, by a different arrangement of their monosyllables, can compose a regular and elegant discourse, and communicate their ideas with energy and precision; nay even with gracefulness and propriety. In these qualities they are not excelled either by the Europeans or Asiatics, who use alphabetical letters. In fine, the Chinese so naturally distinguish the tones of the same monosyllable, that they comprehend the sense of it, without making the least reflection on the various accents by which it is determined.

We must not, however, imagine, as some authors have related, that those people cant in speaking, and make a sort of music which is very disagreeable to the ear; these different tones are pronounced so curiously, that even strangers find it difficult to perceive their difference even in the province of *Kang-nan*, where the accent is more perfect than in any other. The nature of it may be conceived by the guttural pronunciation in the Spanish language, and by the different tones that are used in the French and Italian: these tones are almost imperceptible; they have, however, different meanings, a circumstance which gave rise to the proverb, that *the tone is all*.

If the fineness and delicacy of their tones are such as to be scarce perceptible to a stranger, we must suppose that they do not rise high, but only by small intervals; so that the music of their language must somewhat resemble the music of the birds, which is within a small compass, but nevertheless of great variety of notes. Hence it will follow, that strangers

will find it very difficult, if not impossible, to learn this language; more especially if they have not a delicate ear and a flexible voice, and also much practice. The great difference then between the Chinese and Greek accents consists in this, that the Greeks had but two accents, the grave and acute, distinguished by a large interval, and that not very exactly marked: for the acute, though it never rises above a fifth higher than the grave, did not always rise so high, but was sometimes pitched lower according to the voice of the speaker. The Chinese must have many more accents, and the intervals between them must be much smaller, and much more carefully marked; for otherwise it would be impossible to distinguish them. At the same time, their language must be much more musical than the Greek, and perhaps more so than any language ought to be; but this becomes necessary for the purposes abovementioned. Du Halde is positive, that notwithstanding the perpetual variation of accents in the Chinese tongue, and the almost imperceptible intervals between these tones, their enunciation does not resemble singing: many people, however, who have resided in China, are equally positive that the tone with which they utter their words does actually resemble *canting*; and this, when we consider the almost imperceptible intervals by which they are perpetually raising and lowering the tone of their voice, appears to us highly probable.

As the people of whose language we are treating at present communicate a variety of different significations to their monosyllabic words by their different accentuation, so they employ quantity for the very same purpose. By lengthening or shortening the vowels of their words, they employ them to signify very different things. The same they perform by giving their words different aspirations, as likewise by sounding them with different degrees of roughness and smoothness; and even sometimes by the different motion, posture, or attitude, with which their enunciation is accompanied. By these methods of diversifying their monosyllables (says Du Halde), they make 330 of them serve all the purposes of language, and these too not much varied in their termination; since all the words in that language either terminate with a vowel or with the consonant *n*, sometimes with the consonant *g* annexed.

From this account, we think it is evident that the Chinese, by a wonderful exertion of ingenuity, do, by different tones and prosodical modifications, by means of a very inconsiderable number of words, all invariable radicals, actually perform all that the most polished nations have been able to achieve by their compounds, derivatives, &c. diversified by declensions, conjugations, and flexions of every kind; circumstances which, in our opinion, reflect the greatest honour on their inventive powers.

With respect to the grammar of this language, as it admits of no flexions, all their words being indeclinable, their cases and tenses are all formed by particles. They have no idea of genders; and even the distinction of numbers, which in almost all other languages, even the most unimproved, is marked by a particular word, is in the Chinese only indicated by a particle. They have only the three simple tenses, namely, the past, present, and future; and for want of

Chinese Language. different terminations, the same word stands either for the verb or the verbal substantive, the adjective or the substantive derived from it, according to its position in the sentence.

The Chinese language being composed of monosyllables, and these indeclinable, can scarce be reduced to grammatical rules: we shall, however, attempt to lay before our readers as much of the texture of that singular dialect as may enable them to form some vague idea of its genius and constitution. We shall begin with the letters and proceed regularly to the remaining parts as they naturally succeed each other.

117 Chinese letters or characters

The art of joining the Chinese monosyllables together is extremely difficult, and requires a very long and laborious course of study. As they have only figures by which they can express their thoughts, and have no accents in writing to vary the pronunciation, they are obliged to employ as many different figures or characters as there are different tones, which give so many different significations to the same word. Besides, some single characters signify two or three words, and sometimes even a whole period. For example, to write these words, *god morrow, Sir*, instead of joining the characters which signify *god* and *morrow* with that of *Sir*, a different character must be used, and this character alone expresses these three words. This circumstance greatly contributes to multiply the Chinese characters.

This method of joining the monosyllables is indeed sufficient for writing so as to be understood; but it is deemed trifling, and is used only by the vulgar. The style that is employed, in order to shine in composition, is quite different from that which is used in conversation, though the words are in reality the same. In writings of that species, a man of letters must use more elegant phrases, more lofty expressions, and the whole must be dignified with tropes and figures which are not in general use, but in a peculiar manner adapted to the nature of the subject in question. The characters of Cochin-china, of Tong-king, of Japan, are the same with those of the Chinese, and signify the same things; though, in speaking, these nations do not express themselves in the same manner: of consequence the language of conversation is very different, and they are not able to understand each other; while, at the same time, they understand each other's written language, and use all their books in common.

118 Exceedingly numerous,

The learned must not only be acquainted with the characters that are employed in the common affairs of life, but must also understand their various combinations, and the numerous and multiform dispositions and arrangements which of several simple strokes make the compound characters. The number of their characters amount to 80,000; and the man who knows the greatest number of them is of course the most learned. From this circumstance we may conclude, that many years must be employed to acquire the knowledge of such a prodigious number of characters, to distinguish them when they are compounded, and to remember their shape and import. After all, a person who understands 10,000 characters may express himself with tolerable propriety in this language, and may be able to read and understand a great number of books. The generality of their learned men do not understand above 5,000 or 20,000, and few of their doctors have at-

tained to the knowledge of above 40,000. This prodigious number of characters is collected in their great vocabulary called *Hai-pien*. They have radical letters, which show the origin of words, and enable them to find out those which are derived from them; for instance, the characters of mountains, of trees, man, the earth, of a horse, under which must be sought all that belongs to mountains, trees, man, &c. In this search one must learn to distinguish in every word those strokes or figures which are above, beneath, on the sides, or in the body of the radical figure.

Chinese Language.

Clemens Alexandrinus (see Section *Chaldean*, &c.) informs us, that the Egyptians employed three sorts of characters; the first was called the *epistolary*, which was used in writing letters; the second was denominated *sacred*, and peculiar to the sacerdotal order; the last *hieroglyphical*, which was appropriated to monumental inscriptions and other public memorials. This mode of representation was twofold: one, and the most simple, was performed by describing the picture of the subject which they intended to present, or at least one that resembled it pretty nearly; as when they exhibit the sun by a circle and the moon by a crescent; the other was properly symbolic; as when they marked *eternity* by a serpent with his tail in his mouth, the *air* by a man clothed in an azure robe studded with stars, &c.

The Chinese, in all probability, had the same variety of characters. In the beginning of their monarchy, they communicated their ideas by drawing on paper the images of the objects they intended to express; that is, they drew the figure of a bird, a mountain, a tree, waving lines, to indicate birds, mountains, forests, rivers, &c.

There were, however, an infinite number of ideas to be communicated, whose objects do not fall under the cognizance of the senses; such as the soul, the thoughts, the passions, beauty, deformity, virtues, vices, the actions of men and other animals, &c. This inconvenience obliged them to alter their original mode of writing, which was too confined to answer that purpose, and to introduce characters of a more simple nature, and to invent others to express those things which are the objects of our senses.

These modern characters are, however, truly hieroglyphical, since they are composed of simple letters which retain the signification of the primitive characters. The original character for the sun was a circle, thus ; this they called *ga*: They now represent that luminary by the figure , to which they still give the original name. But human institutions having annexed to these last framed characters the very same ideas indicated by the original ones, the consequence is, that every Chinese letter is actually significant, and that it still retains its significancy, though connected with others. Accordingly the word *t'ai*, which imports "misfortune, calamity," is composed of the letter *mien* "a house," and the letter *ko* "fire;" so that the symbolical character for misfortune is the figure of a house on fire. The Chinese characters, then, are not simple letters without any signification, like those of the Europeans and other Asiatics; but when they are joined together, they are so many hieroglyphics, which form images and express thoughts.

119 And truly hieroglyphical.

Upon the whole, the original characters of the Chi-

Chinese Language.

nese were real pictures (see section of the *Egyptian* language); the next improvement was the symbolical character; the third and last stage is the present mode in which artificial signs have been fabricated, in order to represent such thoughts or ideas as could not be represented by one or other of the methods above described. Du Halde, Vol. II. p. 402, *et seq.* has furnished us with rules for pronouncing the Chinese vowels and consonants; a piece of information which, we apprehend, would be of little consequence to our readers, and which we shall therefore pass over, and proceed to give a brief account of their grammar. As the whole language is composed of monosyllables, and these indeclinable, its grammatical structure must be simple and obvious: we shall only mention what to us appears singular and important.

120 Peculiarities of the Chinese parts of speech.

In the Chinese language there is no diversity of genders or cases, and of consequence no declensions. Very often the noun is not distinguished from the verb; and the same word which in one situation is a substantive, in another may become an adjective, and even a verb.

The adjective always goes before the substantive; but if it follows it, it becomes a substantive.

The cases and numbers are known only by the composition. The plural number is distinguished by the particle *men*, which is common to all nouns; but when the noun is preceded by some word that signifies number, the particle *men* is not annexed.

The Chinese genitive, both singular and plural, when it comes after nouns, is often made by *ti*; and there is no other case in that language. The same particle is sometimes placed after pronouns, as if they were derivatives.

The comparative degree is formed by adding the particle *keng*, which is always set before the noun, and signifies *much*. The particle *to* is sometimes used, which likewise imports *much*.

The Chinese have only three personal pronouns, *ngo* "I," *ni* "thou," and *ta* "he:" these become plural by adding the syllable *men*. They are made possessive by adding the syllable *ti*, as *ngo ti* "mine," *ni ti* "thine," *ta ti* "his." The patronymics are formed by putting the name of the city, country, &c. after the pronoun: *chon* is the pronoun relative *who*, *what*, *which*.

Chinese verbs have only three tenses, the preterperfect, the present, and the future. When there is no particle added to the verb, it is the present; the preterperfect is made by adding the particle *lean*: to distinguish the future tense they use the particle *shang* or *hoi* and these are all the varieties incident to their verbs.

The Chinese language has no words that are properly adverbs; they only become so by custom, or by the place they possess in discourse. They are often obliged to employ several words to express the adverbs of other languages: they have none that are demonstrative, or proper for calling or exhorting; but in their stead they are obliged to use nouns and verbs.

221 Their numerals.

Perhaps our readers may wish to know the Chinese numerals; and may imagine that they bear a resemblance to those of the European or other Asiatic dialects. In this, however they will be disappointed.

They stand as follows:

<i>Y</i>	One
<i>Eut</i>	Two
<i>San</i>	Three
<i>Sacc</i>	Four
<i>Ou</i>	Five
<i>Lou</i>	Six
<i>Tsi</i>	Seven
<i>Po</i>	Eight
<i>Kuou</i>	Nine
<i>Che</i>	Ten
<i>Che y</i>	Eleven
<i>Eut che</i>	Twelve
<i>San che</i>	Thirteen
<i>Pe</i>	One hundred
<i>Eut pe</i>	Two hundred
<i>T shien</i>	One thousand
<i>T ouan</i>	Ten thousand
<i>Che ouan</i>	Twenty thousand
<i>Eut ouan</i>	One hundred thousand
<i>Che ouan</i>	Two hundred thousand
<i>T pe ouan</i>	One million.

Chinese Language.

There are a great many particles proper to numbers in the Chinese language: they are frequently used, and in a way peculiar to it; for every numeral has a particle importing the object to which it is attached. Thus *co* is used for man, and *y co* for a woman, &c. *hoi* is used for illustrious men; *tche* or *tchi* is used for ships, dogs, hens; *mei* is used for pearls and precious things; *feu* is used for books; *teng* is appropriated to oxen and cows; *too* is used for letters and little bundles of paper; *oo* is employed for corn and pulse. Those distinctions indicate a language manufactured on purpose to be employed by people who were too high and too haughty to converse with the vulgar.

The style of the Chinese, in their elaborate compositions, is mysterious, concise, and allegorical, after the eastern manner. It is often obscure to those who do not understand the language thoroughly; and it requires a considerable degree of skill to avoid mistakes in reading an author of elegance and sublimity. Their writers express a great deal in few words; and their expressions are lively, full of spirit, intermingled with bold comparisons and lofty metaphors. They affect to insert in their compositions many sentences borrowed from their five canonical books; and as they compare their books to pictures, so they liken these quotations to the five principal colours employed in painting; and in this their eloquence chiefly consists.

122 Style of the Chinese writers.

They prefer a beautiful character to the most finished picture; and nothing is more common than to see a single page covered with old characters, if they happen to be fair and elegant, sold at a very high price. They honour their characters in the most common books; and when they happen to light by chance upon a printed leaf, they gather it up with the greatest care and respect.

In China there are three varieties of language; that of the common people, that of the people of fashion, and that employed in writing books. Though the first is not so elegant as either of the other two, it is not however inferior to our European languages; though those who are but superficially acquainted with the

Chinese Language. the Chinese may, in fact, imagine it uncouth and barbarous. This low and rude language is pronounced and written many different ways, as is generally the case in other courties.

But a more polished, and at the same time a much more energetic, language, is employed in an almost infinite number of novels; some perhaps true, but many more the vehicles of fiction. These are replete with lively descriptions, characters highly finished, morality, variety, wit, and vivacity, in such a degree as to equal in purity and politeness the most celebrated authors of Europe. This was the language of the Mandarines; and though exquisitely beautiful in its kind, was still inferior to the language of books. This last might be styled the *hyper sublime*; and of this there are several degrees and intervals before an author can arrive at what they call the language of the *kings*. This mode of writing cannot be well understood without looking upon the letters; but when understood, it appears easy and flowing. Each thought is generally expressed in four or six characters: nothing occurs that can offend the nicest ear; and the variety of the accents with which it is pronounced produces soft and harmonious sound.

The difference between the *king* and their other books consists in the difference of the subjects upon which they are written. Those of the former are always grand and sublime, and of course the style is noble and elevated: those of the latter approach nearer to the common affairs and events of life, and are of consequence detailed in the Mandarin tongue. In writing on the sublime subjects no punctuations are used. As these compositions are intended for the learned only, the author leaves to the reader to determine where the sense is complete; and those who are well skilled in the language readily find it out.

The copiousness of the Chinese language is in a great measure owing to the multitude of its characters. It is likewise occasioned, in some degree, by the difference of their signification, as also by the artificial method of their conjunction, which is performed most commonly by uniting them two and two, frequently three and there, and sometimes four and four.

Their books are very numerous and bulky, and of course exceedingly cumbrous. A dictionary of their language was compiled in this century. It consisted of 95 large volumes. An appendix was annexed of 25 volumes. Their other books are voluminous in proportion. The Chinese, one may say, are a nation of learned men. Few people of rank neglected the *belles lettres*; for ignorance in a man of any degree of eminence is deemed an indelible stain on his character.

For their manner of writing, the implements with which they write, and the materials upon which they draw their characters, we must remit our readers to the article WRITING. It would, we believe, afford our readers some pleasure, could we discover and explain the reasons which have hitherto prevented the Chinese from adopting the letters employed from time immemorial by the other nations of Europe and Asia.

The Chinese have ever looked upon themselves as greatly superior to the rest of mankind. In ancient times they entertained such contemptible notions of foreigners, that they scorned to have any further com-

merce with them than to receive their homage. They were indeed, at a very early period, highly revered by the Indians, Persians, and Tartars. In consequence of this veneration, they looked upon themselves as the favourites of heaven. They imagined they were situated in the middle of the earth, in a kind of paradise, in order to give laws to the rest of mankind. Other men they looked upon with contempt and disdain, and deemed them deformed in body and defective in mind, cast out into the remote corners of the world as the dross and refuse of nature. They boasted that themselves only had received from God rational souls and beautiful bodies, in order to qualify them for being sovereigns of the species.

Such are the sentiments of the Chinese, and with such sentiments it is by no means surprising that their improvements in *language*, in *writing*, and other appendages of the *belles lettres*, have not been proportioned to their progress in mechanics. When people are once fully persuaded that they have already arrived at the summit of perfection, it is natural for them to sit down contented, and solace themselves with the idea of their own superior attainments. The Chinese had early entertained an exalted opinion of their own superiority to the rest of mankind; and therefore imagined that they had already carried their inventions to the *ne plus ultra* of perfection; the consequence was, that they could make no exertions to carry them higher.

The Chinese, for the space of 3000 years, had almost no intercourse with the rest of mankind. This was the consequence of their insulated situation.— They, of course, *compared themselves with themselves*; and finding that they excelled all their barbarian neighbours, they readily entertained an opinion that they excelled all the rest of mankind in an equal proportion. This conceit at once stifled the emotions of ambition, and deprived them of all opportunities of learning what was going forward in other parts of the world.

They despised every other nation. People are little disposed to imitate those whom they despise; and this perhaps may be one reason why they are at this day so averse from adopting the European inventions.

A superstitious attachment to the customs of the ancients, is the general character of the Asiatic nations. This is evidently a kind of diacritical feature among the Chinese. The institutions of *Fohi* are looked up to among them with equal veneration as those of *Thoth* were among the Egyptians. Among the latter, there was a law, which made it capital to introduce any innovation into the music, painting, or statuary art, instituted by that legislator. We hear of no such law among the former; but custom established, and that invariably, for a space of 3000 years, might operate as forcibly among them as a positive law did among the people first mentioned. An attachment to ancient customs is often more powerful and more coercive than any law that can be promulgated and enforced by mere human authority. These reasons, we think, may be assigned as the impediments to the progress of the Chinese in the *belles lettres*, and perhaps in the cultivation of the other sciences.

Though the language of the Chinese is confessedly different from all the other known languages in its

Chinese Language.

123; Obstacles to their improvement in science and literature.

123 Their books numerous and bulky,

Chinese
Language.125
Chinese
words
found in
various
other lan-
guages,

character and construction, it contains, however, a great number of words evidently of the same origin with those which occur in other dialects, used by people who, according to the natural course of things, could never have been connected with that remote country. A few of those we shall produce before we conclude this section. We shall begin with the import of the name *China*.

China, or, as the orientals write it, *Sin*, is perhaps the Latin *sinus*, "the bosom, the heart, the middle." The Chinese actually imagine that their country is situated in the very middle of the earth, and of consequence call it *Chan*, "the middle the heart;" a denomination which exactly suits their opinion.

Tu, in Chinese, intimates every thing that falls under the cognizance of the senses, every thing that strikes the sight; in Latin, *tuor*.

Ta, a table, a plank, a figure that renders every thing sensible: 2. To see, to look upon, to appear; Greek *ταπεινο*, whence *ταπεινο*, *tendo*.

Tue, to examine attentively, to inspect carefully.

Tui, the most apparent, chief, principal, first; 2. Lightning, thunder.

Tou, a sign by which to know one, letter of acknowledgment. All these ideas are contained in the Hebrew *תו*, *thu*, *signum*, which we believe has produced the Egyptian *theuth*, the good or godlike man who invented letters, geometry, music, astronomy, &c.

Tai, a dye, a theatre; Greek of old *ταει*, then *ταειμαται*, "to see, to look."

Tan, Latin *tantum*, "so much."

Tan, land, country, region, a syllable annexed to the end of a great number of words. *Aquitani*, *Aquitania*, "a land of water;" *Mauritani*, *Mauritania*, "the land of the Moors." The orientals prefix *s*, whence *Farsistan*, *Farsistan*, "the land or country of the Persians;" *Chusistan*, *Chusistan*, "the country of Chuz;" *Turquestan*, *Turquestan*, "the land of the Turks."

Ti, a chief, an emperor, a title of dignity; whence the Greek *τιο* "to honour;" hence, too, the word *di*, "bright, glorious;" whence *Δις* "Jupiter," *Διός* "divine;" the Latin *Dius*, now *Deus*, "God," and *Divus*, with the *diganima* *Æolicum* inserted; the Celtic *Dhia*, &c. It signified originally "bright, glorious," and was an epithet of the Sun.

Tum, Latin *tumeo*, "to swell."

Liven, "to love;" Hebrew *לב*, *leb*, "the heart;" Latin, *libet*. This word pervades all the dialects of the Gothic tongue, still retaining either the same or a nearly analogous signification.

Li, "letters;" Latin, *lino*, "to danb," as the Chinese actually do in forming their letters.

Lo, "to contain, that which contains;" Celtic, *log*; French, *loge*, *logis*, *loger*.

Lim, "a rule;" hence Latin, *linea*, "a line."

Su, "with;" Greek, *συ*, "with;" Celtic, *cyn*, *cym*; whence Latin, *cum*, *con*, &c.

Xim, "very high, elevated, sacred, perfect;" Latin, *eximius*.

Sin, "the heart;" Persian, *Sin*, "the heart."

Sin, "chief, first;" Celtic, *can*, *cean*, *fan*, "the head;" metaphorically, the chief, the first, the principal; Thibet, "fan, or ken," "great, elevated;" Arabic, *fame*, "to be elevated or raised."

Sin, or *Sing*, "a constellation, a star, an element;" Greek Language. Hebrew, *shem*; Greek, *σημα*, *σημα*; Latin, *signum*.
Sie, "a man of learning;" Goth. Sax. Engl. "see; to see, fecer."

Cem, "a priest;" Hebr. *coben*; Syr. *con*; Egypt. *can*, *cun*.

Quin, "a king;" Celtic, *ken*, *kend*, "head, chief;" Gothic, *lanig*; Germ. Flem. Eng. *king*, also *queen*.

Hu, "a door;" Goth. Germ. Eng. *bus*, *hausen*, *houf*.

Min, "a river;" Welch, *men*, "the water of a river;" Latin, *mano*, "to flow," and perhaps *amonus*, "pleasant."

Hn, "hatred;" Greek, *σνος*, "cruel, horrible, odious"

Kiven, "a dog;" Greek *κυν*, *id*.

Ven, "beauty;" Latin, *Venus*, *venustas*; Iceland, Swed. *ven*, "pleasant;" Scotch, *winsome*.

Han, "the soul, breath;" Greek, *αεμος*; Latin, *anima*, *animus*.

To these instances of the analogy between the Chinese language and those of the other people of Asia and Europe many more might be added; but the preceding, it is hoped, will serve as a specimen, which is all that can be expected from an inquiry of the nature of the present.

SECT. VII. *Of the Greek Language.*126
Origin of
the Greeks,

BEFORE we enter upon the consideration of the essential and constituent parts of this noble language, we must beg leave to settle a few preliminaries, which, we trust, will serve to throw some light upon many points which may come under consideration in the course of the following disquisition.

The Greeks, according to the most authentic accounts, were descended of Javan or Icn, the fourth son of Japhet, the eldest son of the patriarch Noah. The Scriptures of old, and all the orientals to this day, call the Greeks *Ionim* or *Iawnim* or *Javanoth*. We have already observed, in the beginning of the article concerning the Hebrew language, that only a few of the descendants of Ham, and the most profligate of the posterity of Shem and Japhet, were concerned in building the tower of Babel. We shall not now resume the arguments then collected in support of that position; but proceed to investigate the character of that branch of the posterity of Javan which inhabited Greece and the neighbouring regions.

At what period the colonists arrived in these parts cannot be certainly determined; nor is it of great importance in the question before us. That they carried along with them into their new settlements the language of Noah and his family, is, we think, a point that cannot be controverted. We have endeavoured to prove that the Hebrew, or at least one or other of its sister dialects, was the primæval language of mankind. The Hebrew, then, or one of its cognate branches, was the original dialect of the Ionim or Greeks.

Be that as it may, before these people make their appearance in profane history, their language deviates very widely from this original archetype. By what means, at what period, and in what length of time
this

Greek Language. this change was introduced, is, we believe, a matter not easy to be elucidated. That it was progressive, is abundantly certain both from the rules of analogy and reason.

The colonies, which traversed a large tract of country before they arrived at their destined settlements, must have struggled with numberless difficulties in the course of their peregrinations. The earth, during the periods which immediately succeeded the universal deluge, must have been covered with forests, intersected with swamps, lakes, rivers, and numberless other impediments. As the necessities, and a few of the conveniences of life, will always engross the first cares of mankind, the procuring of these comforts will, of necessity, exclude all concern about arts and sciences which are unconnected with these pursuits. Hence we think it probable, that most of those colonies which migrated to a very great distance from the plains of Shinar, which we believe to have been the original seat of mankind, in a great measure neglected the practice of the polite but unnecessary modes of civilization which their ancestors were acquainted with, and practised before the era of their migration. Certain it is, that those nations which continued to reside in the neighbourhood of that centre of civilization, always appear in a cultivated state; while, at the same time, the colonists who removed to a considerable distance appear to have sunk into barbarism, at a period more early than the annals of profane history can reach.

127
Who were long a barbarous people.

—This appears to have been the situation of the primary inhabitants of Greece. Their own historians, the most partial to their own countrymen that can well be imagined, exhibit a very unpromising picture of their earliest progenitors. Diodorus Siculus, in delineating the character of the original men, we believe sketches his draught from the first inhabitants of Greece † He represents them as absolute savages, going out in small parties to make war upon the wild beasts of the field, which (according to him) kept them in continual alarm. “Necessity obliged them to band together for their mutual security; they had not sagacity enough to distinguish between the wholesome and poisonous vegetables; nor had they skill enough to lay up and preserve the fruits of autumn for their subsistence during the winter.” The scholiast on Pindar describes the situation of the inhabitants of Peloponnesus in the following manner †. “Now some have affirmed that the nymphs who officiated in performing the sacred rites, were called *Melissæ*. Of these Mnæseas of Patara gives the following account. They prevailed upon men to relinquish the abominable practice of eating raw flesh torn from living animals, and persuaded them to use the fruits of trees for food.—Melissa, one of them, having discovered bee-hives, ate of the honey-combs, mingled the honey with water for drink, and taught the other nymphs to use the same beverage. She called bees *Μελισσαι*: *Melissæ*, from her own name, and bestowed much care on the management of them.

† Lib. i.

‡ Python. Ode 4.

128
Progress of their civilization.

“These things (says he) happened in Peloponnesus; nor is the temple of Ceres honoured without

nymphs, because they first pointed out the mode of living on the fruits of the earth, and put an end to the barbarous practice of feeding on human flesh. The same ladies too, from a sense of decency, invented garments made of the bark of trees.”

Greek Language.

Hecataeus the Milesian, treating of the Peloponnesians, affirms*, “that before the arrival of the Hellenes, a race of barbarians inhabited that region; and that almost all Greece was, in ancient times, inhabited by barbarians †. In the earliest times (says Pausanias) (o) barbarians inhabited most part of the country called *Illyria*.” The original Greeks, if we may believe an author of deep research and superior ingenuity ‡, were strangers to all the most useful inventions of life. Even the use of fire was unknown till it was found out and communicated by Prometheus, who is thought to have been one of the first civilizers of mankind. Hence Æschylus||, introduces Prometheus commemorating the benefits which he had conferred upon mankind by his inventions, in a strain that indicates the uncultivated state of the world prior to the age in which he flourished. For the entertainment of our readers, we shall translate as much of that passage as suits our present purpose.

* Strabo, lib. 7.

† Id lib. i.

‡ Plin. Nat. Hist.

|| Prometh. versè 441.

—“Of the human race

Now hear the tale, how foolish erst they were;
I taught them thought and exercise of reason;
If aught they saw before, they saw in vain.
Hearing, they heard not; all was shapeless dreams
For a long space of time, at random mixt
In wild confusion: for they neither knew
Tile-cover'd houses standing in the sun,
Nor timber work; but, like the earth-bred ant
They lodg'd in sunless caves dug under ground;
No certain sign had they of winter cold,
Nor of the flow'ry spring, or summer store,
But blindly manag'd all: till I them taught
What time the stars appear, what time they set,
Hard to be scan'd: then arithmetic rare,
That queen of arts, by dint of patient thought
Descry'd, I taught them: and how vocal sounds;
From letters join'd arose.”

This character, though applied to mankind in general, was in reality that of the most ancient Greeks. These forbidding features had been transmitted to the poet by tradition as those of his ancestors: he was a Greek, and of consequence imputes them to all mankind without distinction.

§ Plato.

Phoroneus, the son and successor of Inachus §, is said to have civilized the Argives, and to have taught them the use of some new inventions. This circumstance raised his character so high among the savage aborigines of the country, that succeeding ages ¶ deemed him the first of men. Pelægus obtained the like character, because he taught the Arcadians to live upon the fruit of the fagus, to build sheds to shelter them from the cold, and to make garments of the skins of swine.

¶ Paus. n. lib. 8. c. 1.

But what clearly demonstrates the unpolished character of the most ancient Greeks is, the extravagant

(o) The Greeks borrowed this contemptuous epithet from the Egyptians. See Herod. l. ii. cap. 158.

Greek
Language.

gant honours lavished by them upon the inventors of useful and ingenious arts. Most of these were advanced to divine honours, and became the objects of religious worship to succeeding generations. The family of the Titans afford a most striking instance of this species of adulation. Jupiter, Juno, Mars, Apollo, Venus, Diana, &c. were sprung of this family. By the useful inventions which these personages communicated to the uncultivated nations of Greece, they obtained such lasting and such extravagant honours, that they jultled out the sidereal divinities of the country, and possessed their high rank as long as Paganism prevailed in those regions. To these testimonies of the savagism of the original Greeks, others almost without number might be added; but those adduced in the preceding part of this inquiry will, we hope, satisfy every candid reader as to the truth of the position advanced.

129
A new colony arrives in Greece called Pelasgi.

While matters were in this situation with respect to the primitive Ionim or Greeks, a new colony arrived in those parts which in a few years considerably changed the face of affairs. The people who composed this colony were called *Pelasgi*; concerning whose origin, country, character, and adventures, much has been written, and many different opinions exhibited by the learned. It is not our province to enter into a detail of their arguments and systems; we shall only inform our readers, that the general opinion is, that they were natives either of Egypt or Phœnicia. We have seen a dissertation in manuscript upon this subject from which we are allowed to extract the following particulars.

The author, we think, has proved by very plausible arguments, that these people could not be descendants of the Egyptians nor Phœnicians. He maintains, that the *Pelasgi* were a great and numerous tribe; that they overspread all the coast of Asia Minor from Mount Mycale to Troas; that they were masters at one time of all the Asiatic and Grecian islands; that they overran Greece and many of the neighbouring countries; and all this in less than half a century.—These facts he seems to have proved from Homer, Herodotus, Diodorus Siculus, Pausanias, and other Greek authors of approved authenticity. He shows, that they were a civilized generation; that they were well acquainted with military affairs, legislation, agriculture, navigation, architecture, letters, &c. He insists, that Phœnicia could not at any given period have furnished such a numerous body of emigrants, even supposing the whole nation had emigrated, and left their native country a desert. He believes that this event took place before the invasion of Canaan by the Israelites; that consequently the *Pelasgic* migration was not occasioned by that catastrophe. He has shown, we think by very probable arguments, that the Egyptians in the earliest ages were averse to foreign expeditions, especially by sea: because that people hated this element, and besides could be under no temptation to emigrate; add to this, they were accustomed to live on small matters, and their country was exceedingly fertile and easily cultivated. It appears (says he) from Herodotus, that the *Pelasgi* were not acquainted with the religion of the Zabians, which could not have been the case had they emigrated from either of these countries. He makes it appear, at

least to our satisfaction, that Herodotus is mistaken when he supposes that the deities of Greece were derived from Egypt. He demonstrates, that the names of the greatest part of those deities are of Phœnician extraction; and this opinion he establishes by a very plausible etymological deduction. He asserts, that had the *Pelasgi* been natives of either of the countries above-mentioned, it would be absurd to suppose them ignorant of the names and religious rites of their respective nations. He finds, that the Egyptian and Phœnician colonies, which afterwards settled in Greece, were enemies to the *Pelasgi*, and either subdued or expelled them the country, which, he imagines could scarce have been the case had both parties sprung from the same ancestors. After settling these points, he concludes, that the people in question were the progeny of the Arabian shepherds, who, at a very early period invaded and subdued both the Lower and Upper Egypt. After possessing that country about a century and a half, they were conquered by Amenophis king of the Upper Egypt, who drove them out of the country. Upon this the fugitives retired to Palestine, where Manetho the Egyptian historian loses sight of them, and either through malice or ignorance confounds them with the Israelites. This writer supposes that those fugitives gradually directed their course for the west and north west coasts of Asia Minor, whence they conveyed themselves over to Greece.

Such are the arguments by which the author of the dissertation above-mentioned supports his hypothesis. It is, for aught we know, altogether new, and to us it appears by no means improbable. If our curious readers should wish to know more of this subject, they may consult Gebel's preliminary Discourse to his Greek Dictionary, Lord Monbodo's Inquiry into the Origin and Progress of Language, vol. i. towards the end, and Mr Bryant's Analysis of Ancient Mythology, *pass.*

Be this as it may, nothing is more certain than that the *Pelasgi* were the first people who in some degree civilized the savages of ancient Greece. It is not our business at present to enumerate the many useful inventions which they communicated to the Greeks, at that time worse than barbarians. We deem it however absolutely necessary as an introduction to our subject, to hazard a few conjectures on the language and letters of those adventurers; a point strictly connected with the subject soon to fall under consideration.

Whether we suppose the *Pelasgi* to have been the offspring of the Phœnicians, Egyptians, or Arabian shepherds, it will make little difference as to their language; every man of learning and research is convinced that those three nations, especially at that early period, spoke a dialect of the Hebrew. The *Pelasgi* then, must have spoken a dialect of that language when they arrived in Greece. Perhaps it might have undergone several changes and acquired some new modifications, during so many years as had passed since they began to be a separate nation, and in the course of so many peregrinations. Some monuments of theirs still extant prove this fact beyond all contradiction. As these people incorporated with the aborigines of Greece, the remains of the original language of mankind,

Greek
Language.

130
Who introduce letters into that country.

Greek Language. kind, or at least so much of it as had been retained by them, gradually coalesced with that of the new settlers. From this, we think, it is obvious, that prior to the arrival of the new colonists from the East, the language now current among the two united tribes must have been a dialect of the Phœnician, Arabian, Hebrew, &c. Be that as it may, Herodotus || affirms that the Pelasgi in his time spoke a barbarous language, quite unintelligible to the modern Greeks.

|| Lib. i. cap. 59.

The reason of this difference between the language of the Hellenes or Greeks in the age of Herodotus and that of the remains of the Pelasgi at that period, seems to be this: Prior to the time of that historian, the Greek language had, from time to time, undergone many changes, and received vast improvements; whereas, on the contrary, that of the remnant of the Pelasgi, who were now reduced to a very low state, had remained stationary, and was then just in the same predicament in which it had been perhaps a century after their arrival in the country.

As the Pelasgi, as was observed above, were a people highly civilized and well instructed in the various arts at that time known in the eastern world, they were skilled in agriculture, architecture, music, &c. (p): The presumption then is that they could not be unacquainted with alphabetical writing. This most useful art was well known in the countries from which they emigrated; and of course it is impossible to imagine that they did not export this art as well as the others abovementioned. Diodorus Siculus imagines that § the Pelasgi knew not the use of alphabetical letters, but that they received them from Cadmus and his Phœnician followers; that those letters were afterwards called *Pelasgic*, because the Pelasgi were the first people of Greece who adopted them. This account must go to the score of national vanity, since very soon after he acknowledges * that Linus wrote the exploits of the first Bacchus and several other romantic fables in Pelasgic characters; and that Orpheus, and Pronapides the master of Homer, employed the same kind of letters. Zenobius likewise informs us † that Cadmus slew Linus for teaching characters differing from his. These letters could be none other than the Pelasgic ‡,

§ Lib. 3.

* Ibid.

† Apud Dr Gregory Sharp's Strict. Greek Language.

‡ See Plate X. | Lib. 1, cap. 49.

* Lib. i. e. 38.

Pausanias, in his Attics, relates ||, that he himself saw an inscription upon the tomb of Coræbus, who lived at the time when Crotopus, who was contemporary with Deucalion, was king of the Argives. This inscription then was prior to the arrival of Cadmus; and consequently letters were known in Greece before they were introduced by this chief. It likewise appears from Herodotus himself, that the Ionians were in possession of alphabetical characters before the coming of the Phœnicians. "For (says he) * the Ionians having received letters from the Phœnicians, changing the figure and sound of some

of them, ranged them with their own, and in this manner continued to use them afterwards." If, then, the Ionians (Q) ranged the Phœnician characters with their own, it is obvious that they had alphabetical characters of their own.

Greek Language.

Besides these historical proofs of the existence of Pelasgic characters, monuments bearing inscriptions in the same letters have been discovered in several parts of Greece and Italy, which place this point beyond the reach of controversy. What characters these were may be easily determined. As the Pelasgi emigrated from Arabia, the presumption is that their letters were Phœnician. They are said by Dr Swinton to have been 13 in number, whereas the Phœnician alphabet consists of 16. The three additional letters were probably invented by the latter people after the Pelasgi had left the eastern quarters. The Phœnician letters imported by the Pelasgi were, no doubt, of a coarse and clumsy contexture, unfavourable to expedition in writing, and unpleasant to the sight. Besides, the Phœnician characters had not as yet received their names; and accordingly the Romans, who derived their letters from the Arcadian Pelasgi †, had no names for theirs. The probability is, that prior to this era the Pelasgic letters had not been distinguished by names. They were of course no other than the original letters of the Phœnicians in their first uncouth and irregular form; and for this reason they easily gave way to the Cadmean, which were more beautiful, more regular, and better adapted to expedition.

† Livii lib. 1 c. 7. Plate IX.

Hitherto we have seen the Pelasgi and the Ionians incorporated, living under the same laws, speaking the same language, and using the same letters. But another nation, and one too of vast extent and populousness, had at an early period taken possession of a considerable part of the country afterwards distinguished by the name of *Hellas* or *Greece*. The Thracians were a great and mighty nation; inferior to none except the Indians*, says the father of Grecian history. These people, at a very early period, had extended their quarters over all the northern parts of that country. They were, in ancient times, a learned and polished nation. From them, in succeeding ages, the Greeks learned many useful and ornamental sciences. Orpheus (K) the musician, the legislator, the poet, the philosopher, and the divine, is known to have been of Thracian extraction. Thamyras and Linus were his disciples, and highly respected among the Greeks for their learning and ingenuity. That these people spoke the same language with the Greeks, is abundantly evident from the connection between them and these Thracian bards. The Thracian language, then, whatever it was, contributed in a great proportion towards forming that of the Greeks. From the remains of the Thracian dialect there appears to have been a very strong resemblance between it and the

+ Strabo. lib. 1. &c. 7.

the Chaldean. This position we could readily support by the most plausible etymological deduction, did the limits prescribed us in this article admit such an inquiry. It appears, however, that the † Thracians, Getæ, and Daci or Davi, spoke nearly the same language. The Goths, so much celebrated in the annals of the lower empire, were the descendants of the Getæ and Daci; and consequently retained the dialect of their ancestors. The reader, therefore must not be surpris'd, if in tracing the materials of which the Greek language is compos'd, we should sometimes have recourse to the remains of the Gothic.

132 The Greek language compos'd of three different dialects.

We have now found out three branches of the Greek language; that of the Ionim or *Aborigines*, that of the Pelasgic tribe, and that of the Thracians. These three we imagine were only different dialects of the very same original tongue. This assertion we could readily prove by the comparison of a great number of words taken from the two last, were this a proper place for such a discussion.

132 Arrival of Cadmus in Greece.

Some centuries after the arrival of the Pelasgi, Cadmus, an Egyptian (s) by birth, and a sojourner in Phœnicia, arriv'd in Ecotia with a multitude of followers. This colony chief and his countrymen introduced letters and several other useful improvements into the country in question. As these people were natives of Phœnicia and its environs, their alphabet was that of their native country, consisting of 16 letters. That the Phœnician alphabet was nearly the same with the Samaritan and Hebrew, has been so often and so clearly demonstrat'd by the learned of this and the former century, that it would be altogether superfluous to insist upon it in this short inquiry. The Phœnicians, as is generally known, wrote from right to left, and the old Grecian characters inverted, exactly resemble the other.

† Scaliger.

The names of the Cadmean characters are Syrian †, which shows the near resemblance between that language and the Phœnician. They stand thus: *alpha, betha, gamma, delta* &c. The Syrians used to add *a* to the Hebrew vocables; hence alph becomes alpha, beth, betha or beta, &c. In the Cadmean alphabet we find the vowel letters, which is an infallible proof that this was the practice of the Phœnicians in the age of Cadmus; and this very circumstance furnishes a presumption that the Jews did the same at the same period.

133 The letters introduced by him.

After all it is evident that the oldest Greek letters, which are written from right to left, differ very little from those of the Pelasgi. The four double letters, *β, ς, ζ, γ,* are said to have been added by Palamedes about 20 years before the war of Troy. Simonides is generally supposed to have added the letters *Ϸ, Η, Ψ,* though it appears by some ancient inscriptions that some of these letters were used before the days of Palamedes and Simonides.

In the year of our Lord 1456 seven brazen tables were discovered at Engubium, a city of Umbria in the Apennines, of which five were written in Pelasgic or Etruscan characters and two in Latin. The first of the tables is thought to have been compos'd

about 168 years after the taking of Troy, or 1206 years before Christ. By comparing the inscription on these tables with the old Ionic characters, the curious have been enabled to discover the resemblance.

Greek Language.

The old Ionic character wrote from right to left continued in general use for several centuries; It was compos'd of the Cadmean and Pelasgic characters, with some variations of form, position, and sound, The Athenians continued to use this character till the year of Rome 350. The old Ionic was gradually improv'd into the new, and this quickly became the reigning mode. After the old Ionic was laid aside the * (Βουστροφάδων) Bullrotheadon came into custom, which goes backwards and forwards as the ox does with the plough. They carried the line forward from the left, and then back to the right. The words were all plac'd close together, and a few small letters were used before the fourth century. If our curious readers would wish to know more of letters and alphabets, we must remit them to Chishul, Morton, Postellus, the great Montfaucon, Gebelin, Astle, &c. For our part we are chiefly concern'd at present with the Phœnician and Cadmean systems; and on these perhaps we may have dwelt too long. Having now, we hope, sufficiently prov'd that the Greek alphabet was deriv'd from the Phœnician, in order to convince our curious but illiterate readers of the certainty of our position, as it were by ocular demonstration, we shall annex a scheme of both alphabets, to which we shall subjoin some strictures upon such letters of the Greek alphabet as admit any ambiguity in their nature and application.

134 The old Ionic character.

* Pausan. lib. 5. cap. 17.

135 The Greek alphabet deriv'd from the Phœnician.

A, *alpha*, had two sounds, the one broad like *a* in the English word *all*; the other slender, as *e* in *end*, *spend*, *desend*. The Hebrews certainly used it so, because they had no other letter to express that sound; the Arabs actually call the first letter of their alphabet *elif*; and they as well as the Phœnicians employ that letter to express both the sound of A and E promiscuously. The Greeks call their letter Ε εφίλον, that is, E slender, which seems to have been introduced to supply the place of A slender.

H, *eta*, was originally the mark of the *spiritus asper*, and no doubt answer'd to the Hebrew ה. It is still retained in that capacity in the word Ηεκατον, and in words with the *spiritus asper* beginning books, chapters, sections, &c. E originally marked both the sound of Εφίλον and Ηττα; that is, it was sometimes found short as at present, and sometimes long, where it is now supplied by Η. As it was found convenient to distinguish these two different quantities of sound by different letters, they adopt'd Η, the former *spiritus asper*, to denote the long found of E, and substituted the present *spiritus asper* [] in its place.

I, *iota*, is the Hebrew or Phœnician *jod* or *yod*. We imagine it originally serv'd the purpose of both *iota* and *ypsilon*. It had two different sounds, the one broad and full, the other weak and slender. The latter and the sound of the modern ιψιλον. That this was actually the case, appears in several monumental inscriptions: And upon this depends the variation of some cases

Greek Language. cases of the demonstrative pronoun and of the second declension.

ο, *omicron* or small ο, in the original Greek had three different sounds. It sounded ο short, as at present; and likewise ο long, now denoted by η or large Ο. It likewise marked the sound of the improper diphthong ου, sounded like the English diphthong oo. The η was taken from the Phœnician wau or V.

τ, *psilon*, we have observed before, was adopted to supply a mark for the sound of I leader.

ζ, *zeta*, is compounded of εε. Dion. Halic. however, informs us that this letter should be pronounced εζ, according to the Doric plan.

θ, *theta*, was not known in the old Greek. It is compounded of τ and the *spiritus asper*, both which were of old written separately thus TH.

Ξ, *xi*, is compounded of γε, κε, χε. These letters, too, were originally written separately.

Φ, *phi*. This letter is compounded of β, π, and the *spiritus asper*; thus BH, PH.

Χ, *chi*, like the foregoing, is compounded of γ, κ, and the *spiritus asper* as above.

Ψ, *psi*, like some of the rest, is made up of βε, πε, which, too, were originally written in separate characters.

These observations are thrown together purely for the use of students who may not choose to penetrate into the *minutæ*. We are sorry that the nature of the work will not permit us to extend our researches to greater length. The reader will find an ancient inscription on Plate CCCXC, in which the powers of the letters are exemplified as they were in the first stage of the Greek language. Every language, we believe, was originally composed of inflexible words; the variations which now distinguish nouns and verbs were the effects of progressive improvements. What might have been the state of the Greek language with respect to these variations in its original form, it is not now possible to discover. That it was rude and irregular, will not, we imagine, be controverted. One of the first attempts towards forming the variations, now denominated *declensions* and *conjugations*, would probably be made upon the *demonstrative* article and the *substantive* verb. This observation will be found to hold good in most polished languages. In the Greek tongue, this was evidently the method.

136
Origin and flexion of the article.

The original Greek article was imported from the east. It was the Hebrew or Phœnician ה *ha*. This particle sometimes signifies *one*, and sometimes it answers to our demonstrative *the*; both in its adverbial and demonstrative capacity it imports demonstration. In the earliest stages of the two oriental languages, it was probably written apart, as *ha-mel-eb* "the king." In process of time it came to be joined with the following word, as *Hammel-eb*. From this we think the Greek article was deduced. It is still retained in the Doric dialect in its pristine character. The difference between *ho* and *ha* in the eastern language is nothing. Here then we have the articles ה masculine and ה feminine. Upon these several changes were superinduced, in order to render them more useful for the purposes of language. For those changes we know of no archetype.

The Greeks then having adopted the Hebrew, or Phœnician, or Chaldean article *ha*, and changed it in-

to *ho* for the masculine, seem to have arranged its variations in the following manner:

Greek Language.

<i>Sing.</i>	<i>Plu.</i>
Nom. ο	οι
Gen. ου	ων
Dat. οι	οις
Acc. ον	οις

In the earliest stages of the Greek language, ο and η were sounded in the same manner, or nearly so, as was observed above. The accusative was at first like the nominative; for distinction's sake it was made to terminate in ε, which letter was likewise adopted to characterize the genitive plural; ε was annexed to the dative plural, to distinguish it from the dative singular. The radical word was still without inflexion.

When the article was inflected in this manner, the process stood as follows: we take *λογος* for an example.

<i>Sing.</i>	<i>Plu.</i>
Nom. ο <i>λογος</i> speech	οι <i>λογος</i> speeches
Gen. ου <i>λογος</i> of speech	ων <i>λογος</i> of speeches
Dat. οι <i>λογος</i> to speech	οις <i>λογος</i> to speeches
Acc. ον <i>λογος</i> speech	οις <i>λογος</i> speeches

In this arrangement our readers will observe, that in the time under consideration, ω was not yet introduced; and therefore *ουαρον* or little ο was the same letter in the genitive plural as in the accusative singular; but in the latter case it was sounded long by way of distinction.

The article *η*, which is still retained in the Doric dialect, was varied as follows:

<i>Sing.</i>	<i>Plu.</i>
Nom. η	αι
Gen. ες	ων
Dat. αι	αις
Acc. αν	αις

These variations differ a little from those of the masculine; and they were no doubt made for the sake of distinction, as is usual in such cases. We shall now give an example of the feminine as it must have stood before variations were introduced. We shall employ *τιμη*.

<i>Sing.</i>	<i>Plu.</i>
Nom. η <i>τιμη</i> honour	αι <i>τιμη</i> honours
Gen. ες <i>τιμη</i> of honour	ων <i>τιμη</i> of honours
Dat. αι <i>τιμη</i> to honour	αις <i>τιμη</i> to honours
Acc. αν <i>τιμη</i> honour	αις <i>τιμη</i> honours

Afterwards, when the Chaldean article *ha* was adopted for the neuter gender, the letter η or ε was changed into τ, and prefixed to it; and then the Greeks, who, in their declension of adjectives, always followed the neuter gender, began to prefix it to the oblique cases.

In this manner we think the Greek nouns stood originally; the only change being made upon the article. At length, instead of prefixing that word, and expressing it by itself, they found it convenient to affix a fragment of it to the noun, and so to pronounce both with more expedition. Thus *οι-λογος*, *c. g.* became *λογ-ος*, *ου-λογος* became *λογ-ου*, and of course *οι-οις* and *οι-οις*, &c. The *spiritus asper*, or rough breathing, was thrown away, in order to facilitate the coalition. Nouns of the neuter gender, as was necessary, were distinguished by using υ instead of ε. In Oriental words the Greeks often change ε into υ, and vice versa.

Greek Language. 138 To this mode of flexion the Greeks copied from the Orientals

In this case the Greeks seem to have copied from an eastern archetype. In Hebrew we find an arrangement exactly similar. To supply the place of the pronouns possessive, they affix fragments of the personal: Thus, they write *beni* "my son," instead of *ben-ani*, and *debar-nu* "our words," instead of *d'bir-anu*, &c. The persons of their verbs are formed in the same manner. In this way, in our opinion, the variations of the first and second declensions were produced.

139 Formation of the third declension, and of its cases.

After that a considerable number of their nouns were arranged under these two classes, there remained an almost infinite number of others which could not conveniently be brought into these arrangements; because their terminations did not readily coalesce with the articles abovementioned. These, like nouns of the neuter gender, were in a manner secluded from the society of the two other classifications. It is probable that these for a long time continued indeclinable. At last, however, an effort was made to reduce them into a class as well as the others. All these excluded nouns originally terminated with *o*, which appears from their genitives as they stand at present. By observing this case, we are readily conducted to the termination of the primitive vocable. The genitive always ends in *eo*, which ending is formed by inserting *o* between the radical word and *o*. By throwing out *o* we have the ancient nominative: Thus, *τις*, genitive *τις ος*; taking out *o* we have *τις*, the original inflexible termination. *αυτος*, genitive *αυτου ος*; throw out *o* and you have *αυτος*. *παρ ος*, genitive *παρ ος ος*; take away *o* and there remains *παρ ος*. *ορις*, genitive *οριθ ος*; by throwing out *o* we have *ορις*. *αυαξ*, genitive *αυαξ ος*, *αυαξ ος*. *κρ ος*, genitive *κρ ος ος*, *κρ ος ος*; originally *κρ ος*, because originally *o* had the sound of *u*, as was observed above. *μελ ος*, genitive *μελ ος ος*, *μελ ος ος*. *ειδ ος*, genitive *ειδ ος ος*, *ειδ ος ος*, the old noun. In short, the genitive is always formed by inserting *o* immediately before *o*, which is always the termination of the nominative; and by this rule we easily discover the noun such as it was in its original form.

The dative of this declension was closed with *o* *οριστον*; the same with that of the second, namely, *οριστον*. The accusative commonly terminates with *α*; but was originally ended with *o*. The Romans imitated the Æolian dialect, and they commonly ended it with *em* or *im*. The Greeks, perhaps, in this imitated their progenitors, for *a* was their favourite vowel. The nominative plural ended in *οι*, which nearly resembles the English plural, and was possibly borrowed from the Thracians. The genitive plural in all the declensions ends in *οις*; the dative ends in *οις*, the *o* being inserted to distinguish it from the dative singular. When a strong consonant, which would not easily coalesce with *o*, comes immediately before it, that consonant is thrown out to avoid a harsh or difficult sound. The same then is; the cases of nouns of the first and second declensions consist of the radical word with fragments of the articles annexed, and these were the first classifications of nouns. The other nouns were left out for some time, and might be denominated *neuters*; at length they too were classified, and their variations formed as above. In this process the Greeks deviated from the oriental plan; for these people always declined

their nouns by particles prefixed. Whether the Greeks were gainers by this new process, we will not pretend positively to determine. We are, however, inclined to imagine that they lost as much in periphrasis as they gained by variety.

Greek Language.

140 It is generally believed that the Greeks have no ablative; to this opinion, however, we cannot assent. It is true, that the dative, and what we would call the *ablative*, are always the same: yet we think there is no more reason to believe that the latter is wanting in Greek, than that the ablative plural is wanting in Latin, because in that language both these cases are always alike.

140 Greek ablative.

In the eastern languages there are only two genders, analogous to the established order of nature, where all animals are either male or female. But as the people of the East are, to this day, strongly addicted to personification, they ranged all objects of which they had occasion to speak, whether animate or inanimate, under one or other of these two classes. Hence arose what is now called the *masculine* and *feminine* genders. The orientals knew nothing of a neuter gender, because, indeed, all objects were comprehended under the foregoing classes. The Phœnician feminine was formed from the masculine, by adding *es*, *ab*. In this the Greeks in many cases imitated them. The Greeks and Latins left a vast number of substantives like a kind of outcasts, without reducing them to any gender; this process gave rise to the neuter gender, which imports, that such substantives were of *neither gender*. This has the appearance of a defect, or rather a blemish, in both. Sometimes, too, they make words neuter, which, according to the analogy of grammar, ought to be either masculine or feminine. And again, they range words under the masculine or feminine, which by the same rule ought to have been neuter. In short, the doctrine of general distribution seems to have been very little regarded by the fabricators of both tongues. The beauty which arises from variety seems to have been their only object.

141 Genders.

The use of the article in the Greek language is, we think, rather indeterminate; it is often prefixed to proper names, where there is no need of demonstration or geometrical distinction. On the contrary, it is often omitted in cases where both the one and the other seem to require its assistance. In short, in some cases it seems to be a mere expletive. Though both Lord Monboddo and Mr Harris have treated of this part of speech, neither the one nor the other has ascertained its proper use. (See *Orig. and Progr. of Language*, vol. ii. p. 53. *Hermes*, page 214. *et seq.*).— We know not any objection to the early use of articles among the Greeks so plausible as the total neglect of them among the Romans. But it ought to be considered, that after the flexions were introduced, the use of the article was in a great measure neglected. Accordingly, Lord Monboddo observes that it is very seldom used as such by Homer, but commonly in place of the relative pronoun, *ος, η, ο*.— Thus it would appear, that at the time when the Roman language was reduced to the Grecian standard, the article was not commonly used by the Greeks; and of course the Latins never employed it. There can be no doubt but the pronoun *το*, in the northern languages, is the same with the Greek *ο*, and the Hebrew *לוא*. This among the northern people is al-

142 Further observations on the article.

ways

143
Greek Language, Adjectives.

ways a relative, which affords a presumption that the Greeks originally used the article in the same manner as we do at present. The fact is, that the articles having once got into vogue, were often positively used as mere expletives to fill up a gap; and that on the other hand, when there was no occasion for pointing out an object, it being fully determined by the tenor of the discourse, it was often omitted.

In forming adjectives, they followed the same plan that they had done with substantives. Their great effort was to make their adjectives agree with their substantives in gender, number, and case. This arrangement improved the harmony of speech; and nothing could be more natural than to make the word expressing the quality correspond with the subject to which it belonged.

As adjectives denote qualities, and thus are susceptible of degrees, nature taught them to invent marks for expressing the difference of these degrees. The qualities may exceed or fall below each other by almost numberless proportions; it was, however, found convenient to restrict these increases and decreases to two denominations. The positive is, properly speaking, no degree of comparison at all; therefore we need only point out the formation of the comparative and superlative.

The former is generally thought to be fabricated, by first adding the Hebrew word קָדִים , *excellent*, to the positive, and then affixing the Greek termination ος ; and the latter, by affixing the Syrian word *tab* and the syllable ος , in the same manner.

144
Greek numerals.

Every nation, even the most uncivilized, have early acquired the notion of number. Numerical characters and names are the same in many different languages. These terms were discovered, and in use, long before grammar came to any perfection; and therefore remain either inflexible or irregular. The first way of computing among the Greeks was by the letters of the alphabet; so that Α signified *one* and ΑΒ *twenty four*: in this manner the raphodies of Homer are numbered; and so are the divisions of some of the Psalms, as is generally known. But a more artificial plan of computation was obviously necessary. They divided the letters of the alphabet into *decads* or ten, from Α to Ι = 10. To express the number 6, they inserted Ϛ *hex* = 6; so that by this means the first decade amounted to 10. In the next decade every letter increased by tens, and so Π denoted 100. In this decade they inserted Ϙ *hect* = 100. In the third, every letter rose by 100; so that Ϡ *thous* = 1000. By inserting these three Phœnician characters they made their alphabet amount to 900. To express chiliads or thousands, they began with the letters of the alphabet as before; and to make the distinction, they placed a dot under each character, as the units, tens, hundreds, were distinguished by an acute accent over them.

But in monumental inscriptions, and in public instruments, a larger and more lasting numerical character was fabricated. They began with Ι , and repeated that letter till they arrived at ΙΙ = 5. This is the first letter of πεντα 5. Then they proceeded, by repeating Ι till they came to 10 Δ , the first letter of δεκα ; 10. Then they repeated Δ over and over, so that four Δ = 40. To express 50, they used this me-

thod; they inclosed Δ in the belly of Ω = 50, ΩΩ = 500 ΩΩΩ = 50,000, &c. Often, however, Χ signifies 1000, and then we have *δεκα Χίλια*, 2000, *επι Χίλια*, 3000; and so of the rest.

145
Pronouns.

The word *pronoun* signifies a word placed instead of a noun or name; and indeed the personal pronouns are really such: this needs no explication. The pronoun of the first person is one of those words which have continued invariable in all languages; and the other personals are of the same character. The relatives, possessives, demonstratives, and gentiles, are generally derived from these, as may be discerned by a very moderate adpt in the language. Our reader will therefore, we hope, easily dispense with our dwelling upon this part of speech.

146
Greek verbs, how formed.

Verb. In most ancient languages, verbs, according to the order of nature, have only three tenses or times, namely, the *past*, *present*, and *future*. The intermediate tenses were the invention of more refined ages. —The Greek, in the most early periods, had no other tenses but those abovementioned. The manner of forming these we shall endeavour to point out, without touching upon the nature of the rest, since an idea of them may be acquired from any common grammar.

We have observed above, that the flexion of nouns of the first and second declensions are formed by annexing fragments of the articles to the radical words; and that the variation of the tenses were produced by joining the substantive verb, according to the same analogy. Every Greek verb was originally an inflexible biliteral, triliteral, quadriliteral or dissyllabic radix. The variations were formed a long while after in the manner above intimated.

The Greeks had their substantive or auxiliary verb, from the Phœnician or Chaldean בָּרַח , *fruit*. This verb, taking away the gentle aspirate from both beginning and end, actually becomes ε . This vowel the Greeks brought along with them from the East, and manufactured after their own manner, which appears to have been thus:

Pref.	εω , εες , εε ,	εωων , εεεε , εεεε ,
Cont.	α , εες , εε ,	αωων , εεεε , αωωω ,
Fut.	εωα , εωεε , εεεε ,	εωωων , &c.

We place εεε in the third person plural, because for many centuries εωωνεωων supplied the sound of the diphthong αε . By these variations it will appear that the radical verb was rendered capable of inflexion. We have observed that Greek verbs were a collection of biliteral, triliteral, or quadriliteral, radical words. — The following may serve for examples: ε , αεε , αωε , αωεε , αωεεε , αωεεεε , &c.

These radicals are taken at random; and we believe our Grecian student, by adding the terminations, will readily find them all significant verbs. With these radicals then, and the substantive-verb, we suppose the present and future tenses were formed.

147
Original present that which is now the second person.

But it is now generally admitted that the modern present was not the original one of the verb. The second, or Attic future, appears plainly to have been the most ancient present. When the language was improved, or rather in the course of being improved, a new present was invented, derived indeed from the former, but differing widely from it in its appearance and complexion. Upon this occasion, the old present

148
Greek
Language:

was degraded, and instead of intimating what was *doing of present*, was made to import what was immediately to be done hereafter. By this means, $\gamma\alpha\rho\omega$, contracted into $\gamma\alpha\rho\epsilon$, *I am willing*, came to intimate *I am just going to write*. This change was probably made for the sake of enriching the language, for variety, for energy. Thus $\alpha\omega\omega$ contracted $\alpha\omega\omega$ became $\alpha\omega\omega$, $\alpha\omega\omega$, $\alpha\omega\omega$, &c. According to this theory, we find, that such verbs as now have no second future retain their original form, only the circumflex has been removed in order to accommodate them to the general standard. Grammarians have now chosen the three characteristic letters of active verbs from the present, first future, and perfect. The true characteristic of the original verb was that of the present second future. Many verbs are now destitute of that tense, because, since the invention of the new present, those have fallen into disuse.

149
Formation
of the
modern
present:

Let us now take the verb $\lambda\epsilon\gamma\omega$, *dicō*, in order to make a trial; and let us write the radix and the auxiliary, first separately, and then in conjunction: Thus,

$\lambda\epsilon\gamma\text{-}\omega\omega$, $\lambda\epsilon\gamma\text{-}\omega\omega$, $\lambda\epsilon\gamma\text{-}\omega\omega$, $\lambda\epsilon\gamma\text{-}\omega\omega\omega$, $\lambda\epsilon\gamma\text{-}\omega\omega\omega$, $\lambda\epsilon\gamma\text{-}\omega\omega\omega$.
Then we will have contracted $\lambda\epsilon\gamma\alpha$, $\lambda\epsilon\gamma\omega$, $\lambda\epsilon\gamma\omega$,
 $\lambda\epsilon\gamma\omega\omega$, $\lambda\epsilon\gamma\omega\omega$, $\lambda\epsilon\gamma\omega\omega$. Here we believe every thing is self evident.

The English would run thus: Saying *I am*, saying *dicari*, saying *he is*, &c. At first the radix and the auxiliary were pronounced separately, as we do our helping verbs in English, and would have been written in the same manner had words been then distinguished in writing.

149
First fu-
ture, and

The present first future occupied the same place that it now does, and concurred in its turn to complete the future in conjunction with the radix. That the substantive verb was inflected in the manner above laid down, is obvious from its future middle $\epsilon\sigma\tau\omega\omega$, and from the future of the Latin verb *sum*, which was of old *esō esis*, &c. Verbs in ω , $\mu\omega$, $\nu\omega$, $\rho\omega$, often take ω in the first future. See *Engl. Græc. op. Marm. Oxon.* l. 67. Verbs in α and ι assume σ by analogy, as $\alpha\omega\omega$, $\alpha\omega\omega$, *Eurip. Herub.* v. 1057. $\alpha\omega\omega$ *Hes. Od.* x. v. 511. $\alpha\omega\omega$ $\alpha\omega\omega$, *unde* $\alpha\omega\omega$, *Il.* x. v. 707. $\alpha\omega\omega$, $\alpha\omega\omega$, *Pind. N. M. Od.* 9. *Duodec.* 2. $\alpha\omega\omega$, $\alpha\omega\omega$. *Thes. Lysil.* 22. v. 63. In fine, the Æolic dialect after the liquids often inserts σ .

It must be observed, that the Greeks, in order to accelerate the pronunciation, always throw out the ϵ and ι , except in verbs ending in $\alpha\omega$, $\epsilon\omega$, $\iota\omega$; where they generally change them into ν and σ . When the last letter of the radix can coalesce with σ after ϵ is thrown out, they transform it so as to answer that purpose; if not, they sometimes throw it out. We shall once more take $\lambda\epsilon\gamma\omega$ for an example:

$\lambda\epsilon\gamma\text{-}\omega\omega$, $\lambda\epsilon\gamma\text{-}\omega\omega$, $\lambda\epsilon\gamma\text{-}\omega\omega$, &c.
Throwing out ϵ , it would stand $\lambda\epsilon\gamma\text{-}\omega\omega$, $\lambda\epsilon\gamma\text{-}\omega\omega$, &c. by changing $\gamma\epsilon$ into ξ it becomes $\lambda\epsilon\xi\omega$. $\lambda\theta$ and σ cannot coalesce with σ , therefore they throw them out: thus $\lambda\theta\epsilon$, future first $\alpha\lambda\alpha\omega$; $\lambda\theta\omega$, future first $\lambda\theta\omega\omega$; $\lambda\theta\omega$, $\lambda\theta\omega$, &c.

These are the general rules with respect to the formation of the present and future of active verbs in the oldest stages of the Greek language. The limits prescribed will not allow us to pursue these conjec-

tures; but the reader may, if he thinks proper, carry them a great way.

150
Greek
Language.

The præterite tense falls next under consideration. If we may trust analogy, this, as well as the other two, must have owed its conformation to the radix of the verb, and some other word fitted to eke out its terminations. It has been thought by some critics, that this addition was taken from the Hebrew word $\alpha\omega$; and we should be of the same opinion did not another auxiliary present itself nearer home, which appears to us much more congruous to such a purpose. Perhaps, indeed, the people from whom we suppose it borrowed, derive it from the eastern quarters. We have already observed, that the Thracians were masters of a great part of Greece in the very earliest ages. At that time they were a polite and learned people. From them a considerable part of the Greek language was derived. If, therefore, we should find a word in their language employed for the same purpose, and accommodated to coalesce with the radical verb, we feel ourselves very much inclined to prefer such a word.

150
Præterite
tenses.

The word *ha* pervades many different languages as an auxiliary verb. From it we have the Italian *ha*, the Spanish *le*, the French *ai*; and in one shape or other it appears in all the German and Scandinavian dialects. It is the Gothic auxiliary; and, we believe, it forms the termination of the perfect active of the first conjugation in the Latin tongue: For there *am* is the radix of *amo*; in the præterite *am-hævi*, *amavi*; and the præterperfect *am-hav-erant*, i. e. *amaverant* compounded of *am*, *hav*, and *erant*, the imperfect of the indicative of the substantive verb. This præterite, in the formation of the præterite of Latin verbs, will scarce be questioned, and forms certainly a presumptive proof that the Greeks pursued the same line. From this verb is likewise derived the Latin *hæco*, by changing α into h , which are indeed the same letter. Our readers, after this detail, will not be surpris'd if we should now hazard a conjecture, and declare it as our opinion, that this same Gothic auxiliary *ha* is actually the additional part of the præterite of Greek verbs, and that part upon which the conjugation depends.

151
Origin of
the auxi-
liary verb.

In forming this combination between the radix and the auxiliary, the Greeks were obliged to fabricate several devices. As often as the last letter of the radix could not unite with the aspirate in *ha*, they metamorphos'd it into one of the double letters, which are capable of coalescing with it. In the verb $\lambda\epsilon\gamma\omega$, γ was changed into χ ; thus, $\lambda\epsilon\gamma\text{-}h\alpha$ became $\lambda\epsilon\chi\text{-}h\alpha$, $\alpha\omega\omega$ præterite $\alpha\omega\omega$ *ha*, was combined into $\alpha\omega\omega$. In verbs which had a radix that would not admit this conjugation, they hardened the h into κ , as in $\alpha\omega\omega$, præterite $\alpha\omega\omega$, $\alpha\kappa\omega\omega$. Many other ways were contrived to facilitate this reunion. These are detailed in every Greek grammar, and so need not be mentioned.—What has been said with respect to this configuration, we offer as a pure conjecture, without the most remote intention of obtruding it upon our readers.

If it is admitted, that the auxiliary *ha* formed the conjugating termination of the active verb among the Greeks, it will likewise be admitted, that the radical verb and the other made originally two distinct words: that, according to this scheme, the præterite would

pro-

Greek Language.

proceed thus, εἶμι, said I have; εἶσθε, said thou hast; εἶσι, said he hath, &c. This process to us appears rational, elegant, and advantageous. The plural perfect was not then invented, and therefore it does not come under our consideration. The other tenses were all deduced from those described; and in forming these intermediate distinctive tenses, we believe that both critics and grammarians, and perhaps philosophers too, were employed. See GRAMMAR.

The eastern nations have diversified their verbs, by affixing fragments of the personal pronouns to the radix, by which they gained only the advantage of exhibiting the genders of the persons engaged in being, acting, and suffering; but a perpetual repetition of these was unavoidable. The Greeks, by their artificial combination of the radix with the two auxiliaries, avoided the necessity of repeating their personal pronouns, as we and the other modern inhabitants of Europe are obliged to do; and at the same time, by diversifying the terminations of their nouns and verbs, wonderfully improved the beauty and harmony of their language. The arrangement above insisted on is so very different from that of the orientals, and so entirely Gothic, that we think there can be no doubt that the Greeks borrowed this manœuvre from the Thracians. Every person moderately acquainted with the Greek language will, upon examination, discover a wonderful coincidence between the structure, idioms, and phraseology, of the English and Greek languages: so many congenial features must engender a strong suspicion that there once subsisted a pretty intimate relation between them.

In the preceding deduction, we find ourselves obliged once more to differ from the very learned author of the *Origin and Progress of Language*. As we took the liberty to question his originality of the Greek language, and at the same time presumed to attack the goodly structure raised by philosophers, critics, and grammarians; so that we now totally differ from that learned writer as to his theory of the creation of verbs out of the inhale matter of εἶμι, εἶσθε, &c. This whole fabric, in our opinion, leans on a feeble foundation.

The apparatus of intermediate tenses, of augments, derivation of tenses, with their formation, participles, and idiomatical constructions, and other essentials or appendages, we omit, as not coming within the verge or the disquisition.

The derivation and formation of the middle and passive voices, would certainly afford matter of curious speculation; but the labour necessary to investigate this connection would greatly overbalance the benefit expected.

However, to complete our plan, we shall subjoin a few structures with respect to the formation of the middle voice, which was, in our opinion, immediately formed from the active.

We have seen already, that the active voice in its original state was formed by annexing fragments of the substantive or auxiliary verb to the radix. The same economy was observed in fabricating the flexible parts of the verb of the middle voice. To demon-

strate this, we shall first conjugate the present tense of the auxiliary passive upon the principles above laid down.

Present, εἶμι, εἶσθε, εἶσι, εἶσθε, εἶσθε, εἶσθε. Such was the passive-present of the auxiliary. We shall now take our example from the verb εἶμι; recent future εἶμι, struck I am, εἶσθε, struck thou art, εἶσθε, struck he is, &c. contracted εἶσθε, εἶσθε, εἶσθε. The conjunction and formation here is obvious. Perhaps, in the second person, ε was inserted, which, however, is thrown out in the progress of the persons. The future middle is clearly formed, by adding the future passive of the verb εἶμι, only as ε was introduced into the language for ε long, it was generally (τ) substituted instead of that vowel in verbs ending in εω and εσ, and ε for ε in verbs ending in εα; the two vowels ε and ε being originally long as well as short, till ε was adopted to denote the long sound of the former, and ε that of the latter. In many verbs, before the conjunction of the radix and auxiliary, ε CCCXC. was thrown out: thus, εἶσθε became εἶσθε, εἶσθε, εἶσθε, &c.

The praterite was deduced from that of the active by a very slight variation, so trifling, indeed, that it need not be mentioned; only we may observe, that the aspirate h is never retained in this tense, which originally seems to have been the only distinguishing character by which that tense of the middle-voice differed from the same tense of the active.

From the strict analogy between the mode of forming the three primary tenses of the active and middle voice, we are led to suspect that what is now the middle was originally the passive voice.

The intermediate formation of the former, by annexing the passive auxiliary, is obvious. The middle voice still partakes of the passive signification, since it has sometimes a passive, though more frequently an active. There are several parts of the present passive quite analogous to the same tenses in the middle: and, lastly, it is the common progress, in the course of improvement, to proceed step by step, and by approximation. What is most simple and easy is the first object, then succeeds what is only a little more difficult, and so on till we arrive at the last stage, when human ingenuity can go no farther. Now, it will readily be admitted, that the passive voice is much more embarrassed and intricate in its texture than the middle: and, therefore, the former should have been posterior in point of time to the latter.

We are well aware, that the very learned Kuster, and most other moderns, deeply skilled in the origin, progress, and structure of the Greek language, have thought otherwise. The general opinion has been, that the Greek middle voice answered exactly to the Hebrew conjugation *hithpahal*, and in its primitive signification imported a reciprocity, or when the agent acts upon itself. For our part, we only intended a few hints upon the subject, which our learned readers may pursue, approve, or reject, at pleasure.

If we might pretend to investigate the formation of the passive voice, we should imagine that the modern

152 Derivation and formation of the middle voice,

(τ) We say generally, because in verbs ending in εω, that ε is sometimes retained, as εἶσθε, εἶσθε, εἶσθε.

Greek Language. 153 And of the passive.

den present was formed from the ancient one, by inserting such letters as were found necessary for beauty, variety, energy, &c. ; the first future from the second future middle of the verb τιθημι, once βια. This future is θισσεται; and, joined to the radix, always occupies that place, τι-θησεται, αλεθισσεται, φειχθησεται, πορθησεται, and so of the rest; whether μαι, σαι, ται, which occur so frequently as the terminations of the middle and passive voices, are fragments of some obsolete verb, we will not pretend to determine.

From verbs in αυ, ει, ου, υα, are formed verbs in μι, which in the present, imperfect, and second aorist, as it is called, only have a different form, by assuming μι with a long vowel preceding it, in the present active; which vowel is preferred in each person singular. This collection of irregular verbs seems to be formed from the verb ειμι, which in some dialects might be ημι. Indeed the imperfect ην, ης, η, seems, to imply as much: in this, however, we dare not be positive.

In the whole of this analysis of the formation of verbs, we have laid down what to us appears most plausible. That metaphysical critics may discover inaccuracies in the preceding detail we make no doubt; but our candid readers will doubtless reflect, that no language was ever fabricated by philosophers, and that the elements of language were hammered out by peasants, perhaps, by savages. Critics have created a philosophy of language we admit, and have a thousand times discovered wonderful acuteness and ingenuity in the mechanism of words and sentences, where the original oromathetæ never apprehended any, and which possibly never existed but in their own heated imagination. If our more enlightened readers should find any thing in the preceding detail worthy of their attention, so much the better; if the contrary should happen, we presume they will take up with the hackneyed system. We have all along neglected the dual number, because it regularly follows the type of the other numbers.

Be that as it may, before we drop this subject we must take the liberty to subjoin an observation or two with respect to the consequences of the practice of new modelling the present, and of course the imperfect, tenses of verb. 1st, After this arrangement they commonly retained all the other tenses exactly as they had stood connected with the primitive verb: this needs no example. 2d, They often collected the tenses of verbs, whose present and imperfect were now obsolete in order to supply this defect. Thus we have φερω-οισον, αειρα, ημερα. 3d, They often formed present and imperfect tenses without any other tenses annexed: The poets in particular seem to have fabricated these two tenses at pleasure.

If this procedure was convenient for the poets, it was certainly most incommodious with respect to the vulgar, as well as to foreigners who had an inclination to learn the language. The vulgar, some ages after Homer and Hesiod, must have found it as difficult to understand their poems as our people do to comprehend those of Chaucer and Spenser. By this disposition, too, the etymology of verbs was almost entirely confounded. The present second future being, as has

been observed, the ancient present, the attention of the curious etymologist was naturally diverted to the modern present, where it was utterly impossible to discover the radical word. A few examples will elucidate this point: ανα to strech, to extend, old present ανα; ανα is the radix, which at once appears to be a Persian word signifying a large tract of country. Hence Mauritania "the land of the Mauri," Aquitania, Britania; and with s prefixed Hindo-stan, Chuss-stan, Turque-stan. The obsolete verb οτα, whence οττειται, is evidently derived from ορ, an Egyptian name of the moon; ανα, second future ανα, το φουω, from the Egyptian word φου or fan, a name of the sun: οτατο, future second οτα; οτα is obviously the offspring of οταθη, "a drum or timbrel," from beating or striking, &c. In such etymological researches, the student must be careful to turn the Ionic η into the Doric ε; because the Dorians were latest from the coast of Palestine, and consequently retained the largest share of the Phœnician dialect: thus ηβια, το ρησθαι, turning η into ε becomes εβια. This word, throwing away the termination, becomes εαθ, plainly signifying a win press (υ). It is likewise to be observed, that the Æolians often change α into ε, as ομεε instead of ομεα, &c.

It is not our intention to enter into the arrangement and peculiar constructions of the Greek language. There is, however, one, which we cannot well pass over in silence. As that tongue is destitute of those words which the Latins call gerunds, to supply this defect they employ the infinitive with the article prefixed; thus, εις το ελπει φιλαι, in order to their being friends; απο τω ελκειναι αυτου βασιλευ, from their having elected a king; εκ τω απο φευγειν αυτου εκ της πολεις, from their flying out of the city. In these phrases the infinitive is said to assume the nature of a substantive noun; agreeing with the article before it, exactly as if it were a noun of the neuter gender. Idioms of this kind occur in our own tongue; only with us the verb, instead of being expressed in the infinitive, is turned into the participle. According to this arrangement, the first of the preceding phrases, which, according to the Greek, would stand toward to be friends, in English is, in order to their being friends. This anomaly, then, if indeed it be such, is of no manner of consequence. The French, if we are not mistaken, would express it in the very same manner with the Greek, that is, pour etre amis.

From treating of verbs, we should naturally proceed to the consideration of adverbs, which are so denominated, because they are generally the concomitants of verbs. Every thing relating to that part of speech, in the Greek tongue, may be seen in the Port Royal or any other Greek grammar. Instead therefore of dwelling upon this barren topic, we shall hazard a conjecture upon a point to which the critics in the Greek tongue, as far as we know have not hitherto adverted.

The most elegant and most admired writers of Greece and especially Homer, and after him Hesiod, abound with small particles, which appear to us pure expletives, created as it were to promote harmony, or fill up a blank without sense or signification. How those

Greek Language.

(u) Hence it came to signify rejoicing, from the mirth and revelry attending the treading of the vine press.

Greek Language.

Greek Language.

these expletive particles should abound in that language beyond any other, we think, is a matter not easy to account for. It has been said by the Zouli, that if you extract these nonentities from the poems of that bard, *qui solus meruit dici poeta, a magnum inane*, a mighty blank would be left behind. We would willingly do justice to that pigmy race of words, and at the same time vindicate the prince of poets from that groundless imputation. Plato likewise, the prince of philosophers, has been often accused of too frequently employing those superfluous auxiliaries.

Those particles were no doubt imported from the east. It would be ridiculous to imagine that any description of men, however enthusiastically fond they might be of harmonious numbers, would sit down on purpose to fabricate that race of monosyllables purely to eke out their verses; mere sounds without significance. In the first place, it may be observed, that there is a very strict connection among the particles of all cognate languages. To this we may add, that the not understanding the nature, relations, signification, and original import of those seemingly unimportant terms, has occasioned not only great uncertainty, but numberless errors in translating the ancient languages into the modern. The Greek language in particular loses a considerable part of its beauty, elegance, variety, and energy, when these adverbial particles with which it is replete are not thoroughly comprehended. An exact translation of these small words, in appearance insignificant, would throw new light not only on Homer and Hesiod, but even upon poets of a much posterior date. Particles, which are generally treated as mere expletives, would often be found energetically significant. It is however, altogether impossible to succeed in this attempt without a competent skill in the Hebrew, Chaldaic, Arabian, Persian, and old Gothic languages. We shall here take the liberty to mention a few of these particles which are most familiar, one or other of which occur in almost every line of Homer, and which we believe are either not understood or misunderstood. Such are $\alpha\sigma$, $\delta\eta$, $\mu\epsilon\iota$, $\nu\sigma\tau\omicron\iota$, $\mu\alpha\upsilon$, $\gamma\epsilon$, $\epsilon\pi\iota$, $\alpha\pi\alpha$, $\rho\alpha$, $\gamma\omega$. $\alpha\sigma$ is nothing else but the Chaldaic particle $\delta\eta$, the parent of the English *the*. It likewise signifies *by turns in your turn*: $\delta\eta$, is the same word in the Ionic dialect; $\mu\epsilon\iota$ is a particle of the Hebrew affirmative $\mu\epsilon\iota$ *amen, fides, veritas*. $\mu\alpha\upsilon$, a kind of oath by the moon called *mann*, almost over all the east; hence Dor. $\mu\alpha\upsilon\alpha$; $\gamma\epsilon$, an oath by $\gamma\epsilon$, that is, *the earth*: $\alpha\pi\alpha$, another oath by the same element, probably from the oriental word of the same import; $\rho\alpha$ is a fragment of $\alpha\pi\alpha$, mentioned before; $\gamma\omega$, of $\gamma\omega\alpha$, the *earth*, and $\omicron\upsilon$ or $\omicron\omega$, an Egyptian name of the sun; $\omega\epsilon$ $\alpha\sigma$, a particle which pervades all the dialects of the Gothic language. In this manner we believe all these small words that occur so frequently in the Greek tongue, and which have hitherto been held inexplicable, may be easily rendered in significant terms; and were this done, we believe they would add both beauty and energy to the clauses in which they stand. But this discussion must be left to more accomplished adepts.

136 Prepositions.

We shall not explain the nature of prepositions, because we are convinced that few people will take the trouble to peruse this disquisition who are not already acquainted with their import in language. The Greek prepositions are eighteen in number, which need not

be enumerated here. Most of these might be easily shown to be particles, or fragments deduced from oriental or Gothic words. The use of these words is to connect together terms in discourse, and to show the relation between them. In languages where, as in English, all these relations are expressed without any change on the termination of the nouns to which they are prefixed, the process is natural and easy. The whole is performed by *juxta-position*. But in the Greek and Latin tongues, this effect is produced, partly by prefixing prepositions and partly varying the terminations of nouns. Had the Greeks been able to intimate all those relations by varying the terminations, or had they multiplied their prepositions to such a number as would have enabled them to express these relations without the casual variations, as the northern languages have done; in either case their language would have been less embarrassing than it is in its present state. According to the present arrangement both prepositions and the casual variations are used promiscuously to answer that purpose, a method which appears to us not altogether useful. Though this plan might occasion little embarrassment to natives, it must, in our opinion, have proved somewhat perplexing to foreigners. The difficulty would be, as to the latter, when to adopt the one and when the other expedient.

Another inconveniency arises from the exceeding small number of prepositions in that language, which bear too small a proportion to the great variety of relations which they are appropriated to intimate. This deficiency obliged them often to employ the same preposition to denote different relations; For instance, $\epsilon\pi\iota$ intimates, *in, upon*; as $\epsilon\pi\iota$ $\tau\omicron$ $\lambda\iota\theta\omicron$, *upon the stone*; and then it takes the genitive. $\alpha\upsilon$, It denotes *near upon*; as $\epsilon\pi\iota$ $\tau\omicron$ $\lambda\iota\theta\omicron$, and then it governs the dative. $\alpha\upsilon$. The same preposition signifies *motion towards*; as $\epsilon\pi\iota$ $\tau\omicron$ $\lambda\iota\theta\omicron$, *he fell upon the stone*. In these instances the same preposition intimates three different relations; and, which is still more embarrassing, each of these requires a different case. The difficulty in this instance is so considerable, that even the most accurate of the Greek writers themselves often either forget or neglect the true application. Many examples of this might be adduced, did the limits assigned us admit such illustrations. Every man who has carefully perused the Grecian authors will readily furnish himself with examples.

Again, some prepositions, which indicate different relations, are prefixed to the same case. Thus, $\epsilon\kappa$ signifies *from*; as, $\epsilon\kappa$ $\Delta\iota\omicron\upsilon$ $\Delta\omicron$ $\epsilon\mu\iota\theta\alpha$, *from Jupiter we begin*; $\alpha\pi$ $\epsilon\mu\omicron\upsilon$ $\epsilon\iota\omicron\upsilon$, *from my life, or my course of life*; $\alpha\pi\omicron$ $\tau\alpha\upsilon$ $\theta\upsilon\omicron\tau\omega$, *before the doors*; $\tau\omicron$ $\nu\alpha\upsilon\varsigma$ $\epsilon\gamma\chi\alpha\upsilon\omicron\upsilon\iota$, *an encomium before the victory*; $\alpha\lambda\upsilon\tau\iota$ $\alpha\gamma\alpha\theta\omega\upsilon$ $\alpha\pi\alpha\delta\iota\delta\omega\iota$ $\kappa\alpha\kappa\omega\upsilon$, *to render evil for good*; $\alpha\pi\tau\iota$ $\tau\omicron\upsilon$, *against you*. In these examples, and indeed every where, those prepositions intimate different relations, and yet are prefixed to the same cases. Sometimes the same preposition seems to assume two opposite significations: this appears from the preposition $\alpha\pi\tau\iota$ just mentioned, which intimates both *for, instead of, and against or opposite to*.

What has been observed with respect to the prepositions above mentioned, the reader will readily enough apply to $\kappa\alpha\tau\alpha$, $\mu\epsilon\tau\alpha$, $\delta\iota\omega$, $\tau\epsilon\pi\iota$. These incongruities certainly imply something irregular; and seem to inti-

157 Irregularly used.

mate

Greek Language.

mate that those anomalies were so deeply incorporated with the constitution of the language, that the subsequent improvers found it impossible to correct them. In order to prefix a preposition to a case already distinguished by the affixed termination, appears to us a superfluity at least, if not an absurdity; for certainly it would have been more natural to have said *εκ της ακριβειας*, than *εκ της ακριβειας ακριβεια*. Some very learned men, who have inquired into the origin of language, have been of opinion that prepositions were the last invented species of words. If this opinion is well founded, we may suppose (and we think that this supposition is not altogether improbable) that the casual terminations of the Greek language were first affixed to the radicals, in the manner above exhibited; and that prepositions were afterwards fabricated and prefixed to the cases already in use.

The syntax or construction of the Greek language does not, according to our plan, come within the compass of our present inquiry. This the curious Greek student will easily acquire, by applying to the grammars composed for that purpose. We have already hazarded a few conjectures with respect to the formation of the most important and most distinguished classes of words into which it has been divided by the most able grammarians, without, however, descending to the minutæ of the language. As prepositions are the chief materials with which its other words, especially verbs, are compounded, we shall briefly consider the order in which they probably advanced in this process.

158 Used in composition.

Complex ideas are compounded of a certain number or collection of simple ones. Of those complex notions, some contain a greater and some a smaller number of simple conceptions. In language, then, there are two ways of expressing those complex ideas, either by coining a word to express every simple idea separately, according to the order in which they stand in the mind; or by trying to combine two or more simple terms into one, and by that method to intimate one complex idea, by one single word. The Arabians, notwithstanding all the boasted excellencies of their language, have never arrived at the art of compounding their words, in order to answer this noble purpose; and the sister dialects are but slenderly provided with this species of vocables. The Greeks, of all other nations (except perhaps those who speak the Shanferit language), are unrivalled in the number, variety, propriety, elegance, energy, and expression of their compound terms. The Greeks, like the Arabians, in the earliest stages of their language, had only a collection of radical disjointed words, consisting of the jargons of the aboriginal Greeks, of the Pelasgi, Thracians, &c. How these words were arranged and constructed, we have no data remaining upon which we can found a critical investigation. We must therefore remain satisfied with such probable conjectures as the nature of the case, and the analogy of the language, seem to suggest.

The prepositions were originally placed before the nouns, whose relations they pointed out. For example, let us take the *ζυγατεθνησκατο της ακριβεις*, he died along with herself, or he died out of hand along with the others. These words were arranged thus: *απεθνησκατο συν της ακριβεις*; and *αποθνησκατο συν της ακριβεις*. In this manner

the parts of every compound word were placed separately, at least as much as other words which had no connection.

Greek Language.

159 The first compound words in Greek.

The first compound words of the Greek language were the radical nouns with the article, and the radical part of the substantive or auxiliary verb. The success of this experiment encouraged them to attempt the same in other words. By this noble invention they found themselves able to express, in one word, with ease and significancy, what in other languages, and formerly in their own, required a tedious ambages or circumlocution. In process of time, as their language was gradually melowed, they increased the number of their compounds, till their language, in that respect, infinitely excelled all its present dialects. In this process they were careful to unite such letters as not only prevented asperity and difficulty of pronunciation, but even promoted harmony and elegance. But this was the labour of posterior ages.

The Greeks were entirely ignorant of the derivation or etymology of their language; for this we need only consult Plato's Cratylus, Aristotle's Rhetoric, Demetrius, Phalerus, Longinus, &c. In deducing patronymics, abstracts, possessives, gentiles, diminutives, verbals, &c. from radicals of every kind, they have shown the greatest art and dexterity. Examples of this occur almost in every page of every Greek author. But this extended no farther than their own language; every foreign language was an abomination to the Greeks. But more of this in the sequel.

163 Original materials of the Greek language;

The original materials of the Greek tongue were undoubtedly rough and discordant, as we have described them above. They had been collected from different quarters, were the produce of different countries, and had been imported at very distant periods. It would therefore be an entertaining, if it were possible to discover by what men and by what means this wonderful fabric was founded, erected, and carried to perfection. The writers of Greece afford us no light. Foreigners were unacquainted with that originally insignificant canton. Every thing beyond Homer is buried in eternal oblivion. Orpheus is indeed reported to have composed poems; but these were soon obliterated by the hand of time. The verses now ascribed to that philosophical hero are none of his †. Linus wrote, in the Pelasgic dialect, the achievements of the first Bacchus; Thamyris the Thracian wrote; and Pronapides the master of Homer was a celebrated poet. The works of all these bards did not long survive; and it is a certain fact that the Greek tongue was highly polished even more early than the age in which these worthies flourished. Homer, no doubt, imitated their productions, and some are of opinion that he borrowed liberally from them. The Greeks knew no more of the original character of their language than of the original character and complexion of their progenitors. They allowed, indeed, that their language was originally barbarous and uncouth; but by what means or by what persons it was polished, enriched, and finally arranged, was to them an impenetrable secret.

† Pausan, lib. 1. cap. 22.

We have already demonstrated that the Ionim or aborigines of Greece were a race of barbarians; that consequently their language, or rather their jargon, was of the same texture. The Pelasgi found both

the

Greek Language. 161
Which was carried to its utmost perfection at a very early period.

the people and their speech in this uncultivated state. These people arrived in Greece about the year before Christ 1760. It was then that the language of Greece began to be cultivated. Before the age of Homer the work seems to have been completed. Nothing of consequence was afterwards added to the original stock; on the contrary, not a few moieties were deducted from the Homeric treasure. The Pelasgi, as was said before arrived in Greece *an. ant. Chr. 1760.* Homer is thought to have been born *an. ant. Chr. 1011*; consequently the cultivation of the Greek tongue was completed in a period of about 700 years. But upon the supposition that Orpheus, Linus, Tamyris, &c. wrote long before Homer, as they certainly did, that language was arrived high the standard of perfection two centuries before; by which computation the period of its progress towards its stationary point is reduced to 500 years. But as the Pelasgi were a colony of foreigners, we ought to allow them one century at least to settle and incorporate with the natives, and to communicate their language, laws, manners, and habits to the aborigines of the country. By this deduction we shall reduce the term of cultivation to less than four centuries.

During this period Greece was furiously agitated by tumults and insurrections. That country was divided into a number of independent states, which were perpetually engaged in quarrels and competitions. The profession of arms was absolutely necessary for the protection and preservation of the state; and the man of conduct and prowess, was honoured as a demigod, and his exploits transmitted with eclat to posterity. The Greek tongue was then rough and unpolished; because, like the ancient Romans, the bravest men were more disposed to act than to speak. Every language will take its colour from the temper and character of those who employ it; and had it not been owing to one class of men, the Greek tongue would have continued equally rough to the era of Homer, as it had been a century after the arrival of the Pelasgi.

There has appeared among barbarous or half-civilized people a description of men whose profession it has been to frequent the houses or palaces of the great, in order to celebrate their achievements, or those of their ancestors, in the sublimest strains of heroic poetry. Accordingly we find that the Germans had their *bards*, the Gauls their *scalds*, the Scandinavians their *scalds* or *scaldres*, the Irish their *fileas*, all retained for that very purpose. They lived with their chieftains or patrons; attended them to battle; were witnesses of their heroic deeds; animated them with martial strains; and celebrated their prowess if they proved victorious; or, if they fell, raised the song of woe, and chanted the mournful dirge over their sepulchres. These bards were always both poets and musicians. Their persons were held sacred and inviolable. They attended public entertainments, and appeared in all national conventions. The chief of them were employed in the temples of the gods; and the less illustrious, like our minstrels of old, strolled about from place to place, and exercised their functions wherever they found employment.

162
By the poets, who made a

Among the ancient Greeks there was a numerous tribe of men of the very same description, who were at once poets and musicians, and whose office it was

to celebrate the praises of their heroes, and to transmit their exploits to posterity in the most exaggerated encomiums. These poetical vagrants were styled *Aoidoi* or songsters. Some of them lived in the houses of great men; while others left skillful or less fortunate, strolled about the country in the manner above described. The more illustrious of those *Aoidoi* who were retained in the temples of the gods, were certainly the first improvers of the language of the Greeks. Among the Hebrews, we find the first poetical compositions were hymns in honour of Jehovah, and among the pagans the same practice was established. In Greece, when all was confusion and devastation, the temples of the gods were held sacred and inviolable. There the *Aoidoi* improved their talents, and formed religious anthems on those very models which their progenitors had chanted in the east.

The language of the Greeks was yet rugged and unpolished: their first care was to render it more soft and more flexible. They enriched it with vocabularies suited to the offices of religion; and these we imagine were chiefly imported from the east. Homer everywhere mentions a distinction between the language of gods and men. The language of gods imports the oriental terms retained in the temples, and used in treating of the ceremonies of religion; the language of men intimates the ordinary civil dialect which sprung from the mixed dialects of the country. The priests, no doubt, concurred in promoting this noble and important purpose. From this source the strolling *Aoidoi* drew the rudiments of their art; and from these last the vulgar deduced the elements of polished style.

163
Distinction between the language of Gods and of men.

To these *Aoidoi* of the superior order we would ascribe those changes mentioned in the preceding part of this inquiry, by which the Greek tongue acquired that variety and flexibility, from which two qualities it has derived a great share of that ease, beauty, and versatility, by which it now surpasses most other languages. The diversity of its terminations furnishes a most charming variety, while at the same time the sense is communicated to the reader or hearer by the relation between them. By this economy the poet and the orator are left at liberty to arrange their vocabularies in that order which may be most soothing to the ear, and best adapted to make a lasting impression on the mind.

Few colonies have emigrated from any civilized country without a detachment of priests in their train. The supreme powers, whoever they were, have always been worshipped with music and dancing. The Hebrews, Phoenicians, and Egyptians, delighted in these musical and jocund festivals. The priests who attended the Ionians, Dorians, Æolians, Thebans, Athenians, &c. from the east introduced into Greece that exquisite taste, those delicate musical feelings, which distinguished the Greeks from all the neighbouring nations. Hence that numerous race of onomatopœas, by which the Greek language is invested with the power of expressing almost every passion of the human soul, in such terms as oblige it to feel and actually to assimilate to the passion it would excite. Numberless instances of this occur in every page of Homer, Hesiod, Pindar, Sophocles, Euripides, and even of Aristophanes; to quote instances would be to insult the Greek student.

Greek
Language,

Every body knows that the practice of writing in verse was antecedent to the date of profane composition. Here, then, the *Asiata* and the ministers of religion chiefly displayed their skill and discernment. By a judicious mixture of short and long syllables; by a junction of consonants which naturally slide into each other; by a careful attention to the rhythm, or harmony resulting from the combination of the syllables of the whole line—they completed the metrical tone of the verse, guided by that delicacy of musical feeling of which they were possessed before rules of prosody were known among men.

Much liberty was certainly used in transposing letters, in varying terminations, in annexing prefixes and affixes, both to nouns and other kinds of words where such adjuncts were possible: and upon this occasion we think it probable, that those particles of which we have spoken above were inserted like filling stones thrust in to stop the gaps or chinks of a building. Verses were then clumsy and irregular, as the quantity of vowels was not duly ascertained, and the collision of heterogeneous consonants not always avoided. Probably these primitive verses differed as widely from the finished strains of Homer and his successors, as those of Chaucer and Spencer do from the smooth polished lines of Dryden and Pope.

164
Earliest
poets of
Greece.

The poetical compositions of the earliest Greeks were not, we think, in the hexameter style. As they were chiefly calculated for religious services, we imagine they resembled the Hebrew iambs preserved in the song of Aaron and Miriam, Deborah and Barak, Psalms, Proverbs, &c. which were indeed calculated for the same purpose. Archilochus perhaps imitated these, though the model upon which he formed his iambs was not generally known. The later dramatic poets seem to have copied from the same archetypes. Hexameters, it is probable, were invented by Orpheus, Linus, Tamyris, Mææus, &c. The first of these travelled into Egypt, where he might learn the hexameter measure from that people, who used to bewail *Manros* and *Osiris* in elegiac strains. This species of metre was first consecrated to theology, and the most profound sciences of moral and natural philosophy; at length it was brought down to celebrate the exploits of kings and heroes.

*Res gestas regumque, ducumque et fortia bella,
Quo scribi possent numero monstravit* Homerus.

We have hazarded a conjecture above, importing that the earliest poetical compositions of the Greeks were consecrated to the service of the gods. We shall now produce a few facts, which will furnish at least a presumptive evidence of the probability of that conjecture.

165
Orpheus.

Orpheus begins his poem with ancient chaos, its transformations and changes, and pursues it through its various revolutions. He then goes on to describe the offspring of Saturn, that is time, the æther, love, and light. In short, his whole poem is said to have been an oriental allegory, calculated to inspire mankind with the fear of the gods, and to deter them from murder, rapine, unnatural lusts, &c.

166
Mææus.

Mææus was the favourite scholar of Orpheus, or perhaps his son. He composed prophecies and hymns,

and wrote sacred instructions, which he addressed to his son. He prescribed atonement and lustrations; but his great work was a Theogony, or History of the Creation, &c.

Greek
Language,

167
Melampus
Melampus brought the mysteries of Proserpine from Egypt into Greece. He wrote the whole history of the disasters of the gods. This feat is mentioned by Homer himself.

168
Olen.
Olen came from Lycia and composed the first hymn that was sung in Delos at their solemnities; he probably emigrated from Patara a city of Lycia, where Apollo had a celebrated temple and oracle.

The Hyperborean damsels used to visit Delos where they chanted sacred hymns in honour of the Delian god.

169
Homer and
Hesiod.
To these we add the great Homer himself, if indeed the hymns commonly annexed to the *Odyssey*, are his composition. Hesiod's Theogony is too well known to need to be mentioned.

From these instances we hope it appears, that the origin of the poetry of Greece is to be found in the temples; and that there, its measure, numbers, rhythm, and other appendages were originally fabricated.

The Grecian poets, however, enjoyed another advantage which that class of writers have seldom possessed, which arose from the different dialects into which their language was divided. All those dialects were adopted indifferently by the prince of poets; a circumstance which enabled him to take advantage of any word from any dialect, provided it suited his purpose. This, at the same time that it rendered verification easy, diffused an agreeable variety over his composition. He even accommodated words from Macedonia, Epirus, and Illyricum, to the purposes of his versification: Besides, the laws of quantity were not then clearly ascertained; a circumstance which afforded him another conveniency. Succeeding poets did not enjoy these advantages, and consequently have been more circumscribed both in their diction and numbers.

170
Different
dialects
with their
origin.

The Greek language, as is generally known, was divided into many different dialects. Every sept, or petty canton, had some peculiar forms of speech which distinguished it from the others. There were, however, four different dialectical variations which carried it over all the others. These were the Attic, Ionic, Æolic, and Doric. These four dialectical distinctions originated from the different countries in the east from which the tribes respectively emigrated. The Attics consisted, 1st, of the barbarous aborigines; 2d, of an adventitious colony of Egyptian Saites; 3d, a branch of Ionians from the coast of Palestine. These last formed the old Ionian dialect, from which sprung the Attic and modern Ionic. The Æolians emigrated from a different quarter of the same coast; the inhabitants of which were a remnant of the old Canaanites, and consequently different in dialect from the two first mentioned colonies. The Dorians sprang from an unpolished race of purple fishers on the same coast, and consequently spoke a dialect more coarse and rustic than any of the rest. These four nations emigrated from different regions; a circumstance which, in our opinion, laid the foundation of the different dialects by which they were afterwards distinguished.

It

Greek Language. It is impossible in this short sketch to exhibit an exact view of the distinguishing features of each dialect. Such an analysis would carry us far beyond the limits of the article in question. For entire satisfaction on this head, we must refer the Grecian student to Muraire's *Grecæ Linguae Dialecti*, where he will find every thing necessary to qualify him for understanding that subject. We shall content ourselves with the few observations following.

The Athenians being an active, brisk, volatile race, delighted in contractions. Their style was most exquisitely polished. The most celebrated authors who wrote in that dialect were the following: Plato, Thucydides, Xenophon, Demosthenes, and the other orators; Æschylus, Euripides, Sophocles, Aristophanes, Menander Diphilus, with the other comic and tragic poets. That dialect was either ancient or modern. The ancient Attic was the same with the Ionic.

The Ionic, as was said, was the ancient Attic; but when that nation emigrated from Attica and settled on the coast of Asia Minor, they mingled with the Carians and Pelasgi and of course adopted a number of their vocables. They were an indolent, luxurious, and dissolute people; of course their style was indeed easy and flowing, but verbose, redundant, and without nerves. This, however, is the least style in Homer; and after him a prodigious number of writers on every subject have used the same dialect, such as Herodotus of Halicarnassus the celebrated historian; Ctesias of Cnidus the historian of Persia and India; Hecataeus of Miletus; Megasthenes the historian, who lived under Seleucus Nicator; Hippocrates the celebrated physician of Coos; Hellanicus the historian often mentioned with honour by Polybius; Anacreon of Teia; Alcaeus, Sappho of Lesbos, excellent poets; Theoclydes Syrus the philosopher, and a multitude of other persons of the same profession, whom it would be superfluous to mention upon the present occasion.

The Æolic and Doric were originally cognate dialects. When the Dorians invaded Peloponnesus and settled in that peninsula, they incorporated with the Æolians, and their two dialects blended into one produced the new Doric. The original Dorians inhabited a rugged mountainous region about Ossa and Pindus, and spoke a rough unpolished language similar to the soil which they inhabited. Andreas Schottus, in his observations on poetry, l. 2. cap. 50. proves from an old manuscript of "Theocritus, that there were two dialects of the Doric tongue, the one ancient and the other modern; that this poet employed Ionic and the modern Doric; that the old Doric dialect was rough and cumbersome; but that Theocritus has adopted the new as being more soft and mellow." A prodigious number of poets and philosophers wrote in this dialect, such as Epicharmus the poet; Ibycus the poet of Rhegium; Corinna the poetess of Thebes, or Thebes, or Corinth, who bore away the prize of poetry from Pindar; Erynnia a poetess of Lesbos; Moschus the poet of Syracuse; Sappho the poetess of Mytilene; Pindarus of Thebes the prince of lyric poets; Archimedes of Syracuse the renowned mathematician; and almost all the Pythagorean Philosophers. Few historians wrote in that dialect; or if they did, their works have not

fallen into our hands. Most of the temples of the gods were completed in Doric; a circumstance which evinces the antiquity of that dialect, and which, at the same time, proves its affinity to the oriental standard.

After that the Greek tongue was thoroughly polished by the steps which we have endeavoured to trace in the preceding pages, conscious of the superior excellency of their own language, the Greeks, in the pride of their heart, stigmatized every nation which did not employ their language with the contemptuous title of *barbarians*. Such was the delicacy of their pumpered ears, that they could not endure the unartificial voice of the people whom they called *barbarians*. This extreme delicacy produced three very pernicious effects; for, 1st, it induced them to metamorphose, and sometimes even to mangle, foreign names, in order to reduce them found to the Grecian standard; and, 2d, it prevented their learning the languages of the east, the knowledge of which would have opened to them an avenue to the records, annals, antiquities, laws, customs, of the people of those countries, in comparison of whom the Greeks themselves were of yesterday, and knew nothing. By this unlucky bias, not only they, but even we who derive all the little knowledge of antiquity we possess through the channel of their writings, have suffered an irreparable injury. By their transformation of oriental names they have in a manner stopped the channel of communication between the histories of Europe and Asia. This appears evident from the fragments of Ctesias's Persian history, from Herodotus, Xenophon, and all the other Grecian writers who have occasion to mention the intercourse between the Greeks and Persians. 3d, It deprived them of all knowledge of the etymology of their own language, without which it was impossible for them to understand its words, phraseology, and idioms, to the bottom. We mentioned Plato's Cratylus above. In that dialogue, the divine philosopher endeavours to investigate the etymology of only a few Greek words. His deductions are absolutely childish, and little superior to the random conjectures of a school boy. Varro, the most learned of all the Romans, has not been more successful. Both stumbled on the very threshold of that useful science; and a scholar of very moderate proficiency in our days knows more of the origin of these two noble languages, than the greatest adepts among the natives did in theirs. By prefixes, affixes, transpositions of letters, new conjunctions of vowels and consonants for the sake of the music and rhythm, they have so disguised their words, that it is almost impossible to develope their original. As a proof of this, we remember to have seen a manuscript in the hands of a private person where the first twelve verses of the Iliad are carefully analysed; and it appears to our satisfaction that almost every word may be, and actually is, traced back to a Hebrew, Phœnician, Chaldean, or Ægyptian original; and we are convinced that the same process will hold good in the like number of verses taken from any of the most celebrated poets of Greece. This investigation we found was chiefly conducted by reducing the words to the original inviolable state, which was done by stripping them of

172
Greek Language.
Beauty of the Greek Language.

prefixed, and so, &c. These figures are, we think, well founded; and consequently need no apology to protect them.

These imperfections, however, are counterbalanced by numberless excellencies: and we are certainly much more indebted to that incomparable people for the information they have transmitted to us through the medium of their writings, than injured by them in not conveying to us and themselves more authentic and more ample communications of ancient events and occurrences. Without fatiguing our readers with superfluous encomiums on a language which has long ago been extolled perhaps to an extravagant degree by the labours of men of the most enlarged capacity and the most refined taste, we shall now proceed to make a few observations on *spirits* and *accents*: which being rather appendages than essentials of the language, we have on purpose reserved for the last place.

173
The spiritus asper and lenis.

Every word in the Greek language beginning with a vowel is marked with a spirit or breathing: This aspiration is double, namely *lenis et asper*, "the gentle and rough or aspirated." The gentle accent, though always marked, is not now pronounced, though in the earliest periods of the language it was undoubtedly enounced, though very softly. Both these aspirations were imported from the east. They were actually the Hebrew *she* and *sheth*. The former denoted the *spiritus lenis*, and the latter the *spiritus asper*. The Hebrew prefixed *he* or *he* to words beginning with a vowel, and of course the Greeks followed their example. These people seem to have delighted in aspirates; and of consequence the letter *sigma* is, some think, rather too often affixed to the terminations of their words. Every word beginning with *phi* had the aspirate joined to *phi*, probably with a design to render the aspiration still more rough.

174
The accents.

The Greek accents are three in number; the acute, the grave, and the circumflex. The acute raises and sharpens the voice; the grave depresses and flattens it; the circumflex first raises and sharpens the voice, and then depresses and flattens it. It is obviously composed of the other two. The learned author of the *Origin and Progress of Language* has taken much pains to prove that these accents were actually musical notes, invented and accommodated to raise, depress, and suspend the voice, according to a scale of musical proportions. It is scarce possible, we think, for a modern Greek scholar to comprehend distinctly the ancient theory of accents. These the native Greeks learned from their infancy, and that with such accuracy, that even the vulgar among the Athenians would have hissed an actor or actress off the stage or an orator off the pulpitum †, on account of a few mistakes in the enunciation of those notes.

See Philo-
log. tom.

These elevations, depressions, and suspensions of the voice upon certain syllables, must have made the language found in the ears of foreigners somewhat like recitative, or something nearly resembling *cant*. But the little variety of those syllabic tones, and the voice not resting upon them, but running them on without interruption, sufficiently distinguished them from music or *cant*. Be that as it may, we think it highly probable, that the wonderful effects produced by the harangues of the orators of Greece on the enraptured minds of their hearers, were owing in a good

measure to these artificial musical tones by which their syllables were so happily diversified. Greek Language.

To this purpose we shall take the liberty to transcribe a passage from Dion. Halic. *De Structura Orationis*, which we find translated by the author of the *Origin and Progress of Language*, vol. ii, book 3d, part ii, chap. 7, page 381. "Rhetorical composition is a kind of music differing only from song or instrumental music, in the degree, not in the kind; for in this composition the words have melody, rhythm, variety or change, and what is proper or becoming; so that the ear as it, as well as in music, is delighted with the melody. moved by the rhythm, is fond of variety, and desires with all these what is proper and suitable. The difference, therefore, is only of greater and less."

With respect to accents, it may be observed that only one syllable of a word is capable of receiving the acute accent, however many there be in the word. It was thought that the raising the tone upon more than one syllable of the word, would have made the pronunciation too various and complicated, and too like chanting.

The *grave accent* always takes place when the acute is wanting. It accords with the level of the discourse; whereas the acute raises the voice above it.

The *circumflex accent* being composed of the other two, is always placed over a long syllable, because it is impossible first to elevate the voice and then to depress it on a short one. Indeed among the Greeks a long syllable was pronounced like two short ones; and we apprehended it was sometimes written so especially in latter times. It is also, either obvious from two learned Greek authors, Dion. Halic. And Aristoxenus, that the Greek accents were actually musical notes, and that these tones did not consist of loud and low, or simply elevating and depressing the voice; but that they were uttered in such a manner as to produce a melodious rhythm in discourse.

In a word, the acute accent might be placed upon any syllable before the antepenult, and rise to a *syss* in the diatonical scale of music; the grave fell to the third below it. The circumflex was regulated according to the measure of both, the acute always preceding. The grave accent is never marked except over the last syllable. When no accent is marked, there the grave always takes place. Some words are called *enclitics*. These have no accent expressed, but throw it back upon the preceding word. The circumflex, when the last syllable is short, is often found over the penult, but never over any other syllable but the last or the last but one.

The ancient Greeks had no accentual marks. They learned those modulations of voice by practice from their infancy; and we are assured by good authority, that in pronunciation they observe them to this day. The accentual marks are said to have been invented by a famous grammarian, Aristophanes of Byzantium, keeper of the Alexandrian library under Ptolemy Philopater, and Epiphanes, who was the first likewise who is supposed to have invented punctuation. Accentual marks, however, were not in common use till about the 7th century; at which time, they are found in manuscripts. If our curious readers would wish to enter more deeply into the theory of accents, we must

175
The ancient Greeks had no accentual marks.

Greek Language. must remit them to Origin of Language, vol. ii. l. 2. *passim*; and to Mr Follet's Essay on the different Nature of Accent and Quantity.

Greek Language.

Such, in general, are the observations which we thought the nature of our design oblig'd us to make on the origin and progress of the Greek language. Some of our more learned readers may perhaps blame us for not intermixing the whole disquisition with quotations from the most celebrated writers in the language which has been the object of our researches. We are well aware that this is the general practice in such cases. The books were before us, and we might have transcribed from them more quotations than the nature of an article of this kind would permit. In the first part there were no books in that language to quote from, because the Greeks knew nothing of their own origin, nor of that of their language, and consequently have recorded nothing but dreams and fictions relating to that subject. Even when we had made considerable progress in our inquiry, the nature of the plan we have adopted excluded in a great measure the use of quotations. When we drew near the conclusion, we imagined that our learned readers would naturally have recourse to the passages alluded to without our information, and that the unlearned would not trouble themselves about the matter. The Greek student who intends to penetrate into the depths of this excellent language, will endeavour to be thoroughly acquainted with the books after mentioned.

176
Books to be studied by every one who wishes to be a master of this language.

Aristotle's Rhetoric and Poetics, his book *De Interpretatione*, especially with Ammonius's Commentary. Ammonius was a native of Alexandria, and by far the most acute of all the ancient grammarians.

Dion. Halic. *De Structura Orationis*, where, amidst abundance of curious and interesting observations, will be found the true pronunciation of the Greek letters.

Demetrius Phalereus *De Elocutione*; a short Essay indeed, but replete with instruction concerning the proper arrangement of words and members in sentences.

See Gaza.

Longinus, the prince of critics, whose remains are above commendation. Theodorus Gaza † and the other refugees from Constantinople, who found an hospitable reception from the munificent family of the Medici, and whose learned labours in their native language once more revived learning and good taste in Europe. These, with some other critics of less celebrity, but equal utility, will unlock all the treasures of Grecian erudition, without however disclosing the source from which they flowed. To these one might add a few celebrated moderns, such as Mons. Fourmont the Elder, Mons. Gebelin, Abbé Pezron, Salmasius, and especially the learned and industrious Lord Monboddo.

We shall now give a very brief account of the vast extent of the Greek language even before the Macedonian empire was erected: at which period, indeed, it became in a manner universal, much more than ever the Latin language could accomplish notwithstanding the vast extent of the Roman empire.

177
Vast extent of the Greek language.

Greece, originally Hellas, was a region of small extent, and yet sent out many numerous colonies into different parts of the world. These colonies carried their native language along with them, and industriously diffus'd it wherever they formed a settlement. The Iones,

Zeoles, and Dores, possess'd themselves of all the west and north-west coast of the Lesser Asia and the adjacent islands; and there even the barbarians learned that polished language. The Greek colonies extended them selves along the south coast of the Euxine sea as far as Sinope, now Trabizond, and all the way from the west coast of Asia Minor: though many cities of barbarians lay between, the Greek tongue was understood and generally spoken by people of rank and fashion.

There were Greek cities on the north coast of the Euxine sea to the very eastern point, and perhaps beyond even those limits; likewise in the Taurica Chersonesus, or Chim Tartary; and even to the mouth of the Danube, the straits of Caffa, &c. In the neighbourhood of all these colonies, the Greek language was carefully propagated among the barbarians, who carried on Commerce with the Greeks.

A great part of the south of Italy was planted with Greek cities on both coasts; so that the country was denominated *Magna Græcia*. Here the Greek tongue universally prevail'd. In Sicily it was in a manner vernacular. The Ionians had sent a colony into Egypt in the reign of Pianmitichus; and a Greek settlement had been formed in Cyrenia many ages before. The Phocians had built Maffilia or Marseilles as early as the reign of Cyrus the Great, where some remains of the Greek Language are still to be discovered. Caesar tells us, that in the camp of the Helvetii registers were found in Greek letters. Perhaps no language ever had so extensive a spread, where it was not propagated by the law of conquest.

The Greek tongue, at this day, is confin'd within very narrow limits. It is spoken in Greece itself, except in Epirus, and the western parts of Macedonia. It is likewise spoken in the Grecian and Asiatic islands in Candia or Crete, in some parts of the coast of Asia Minor, and in Cyprus: but in all these regions, it is much corrupted and degenerated.

178
Spoken as presents.

As a specimen, we shall insert a modern Greek song, and the advertisement of a quack medicine, which, with other plunder, was brought by the Russians from Chochim or Chotzim in 1772.

Song in modern Greek.

ΜΙ δυστυχίαις πολυαῖς μί βλάστη ὡς το γένω
Εἶμαι, καὶ κατηνεία, καὶ να χαθῶ κοιτιῶ
Στα πέλαγος σου συμφερῶν με ἵπτικινδωνῶ κινεῶ
Μ' ἀνίμωις ἀλάβρις σφοδρῆς καὶ ἐπιτιμῶ.
Με κῆματα πολλῶν καὶ μὴν τιφῶν σπασασμῶν.
Θάλασσα σκυρομένη, πολλὰ ἀγρίμωι η,
'Ὅσῳ ἀρριζὶ καὶ ἐπτα με σαυ ἀνέκτα περιστά.
Σύνεφα σποτισμένα καὶ κατασιγῆσιμῆνα,
καὶ να φαῖν μια σπερῆνα, να ἰδῶν τὰ νάτια κινεῆσινα.
Γλιχῶ νεφῶ να ευρῶ, μασχῶ καὶ δειν ἡξείρῶ,
Ν' ἀράξω καὶ δειν νηπορῶ γιατί κινεῶ δειν δειρῶ,
Μ' ἀτελιστῆνα φρίχῶ στα ἀρμῶνα τῆ ἡχῶ.
Ἦθ με αὐτα καὶ να τιζῶ ἢ σε ἀμῆτι κινεῶ,
καὶ τατα ἀν βαρῶζει, ἐμτορῶν να με σολῶζει.

Translation.

With dire misfortunes, pains and woes,
O'erwhelm'd ingulph'd, I struggling fight;
O'er my frail bark proud billows close
To plunge her deep in lalling night.

Bough

Greek Language.

Rough fens of firs incessant roar,
 Pierce winds adverse, with howling blast,
 Heave surge on surge. Ah! far from shore
 My found'ring skiff shall sink at last.
 Involv'd in low'ring darksome clouds,
 Mid sultry fogs, I pant for breath;
 Huge foaming billows rend my shrouds,
 While yawning gulphs extend beneath.
 From bustling clouds loud thunders roll,
 And deaf'ning peals terrific spread;
 Red lightnings dart from pole to pole,
 And burst o'er my devoted head.
 When shall the friendly dawning rays
 Guide me to pleasures once possess'd;
 And breezy gales, o'er peaceful seas,
 Whiff to some port of endless rest?
 In dark despair, with terrors tost,
 I year my sail from side to side.
 Conduct me, Heav'n! to yond' fair coast,
 Or plunge me in the whelming tide.

The Quack Bill.

Instead of giving a literal and bald translation of this advertisement, which runs exactly in the style of other quack bills, it may be sufficient to observe, that the medicine recommended is fluid, when taken inwardly, to raise the spirits, remove costiveness and inveterate coughs; to cure puffs of the breast, and belly-aches; to assist respiration, and remove crum female obstructions. When applied externally, it cures wounds and sores, whether old or fresh, removes ringing of the ears, softens the teeth when loose, and strengthens the gums.

All this and much more, it is said to do in a wonderful manner; and is declared to be the true royal balsam of Jerusalem, and an universal specific.

It is indeed next to a miracle that so many monuments of Grecian literature are still to be found among men. Notwithstanding the burning of the famous library of Alexandria, and the blood numberless wars, massacres, and devastations, which have from time to time in a manner desolated those countries where the Greek language once flourished; we are told that

there still remain about 3000 books written in that language. Greek Language.

We shall now conclude this section with a brief detail of the most distinguished stages and variations through which this noble tongue made its progress from the age of Homer to the taking of Constantinople, *an. post. Chr.* 1453; a period of more than 2000 years. 179

Homer gave the Greek poetry its colour and consistency, and enriched as well as harmonized, the language. It seems, from the coincidence of epithets and cadence in Homer and Hesiod, that the Greek heroic verse was formed spontaneously, by the old *Aeoloi* a sort of improvisatori; and that Homer and his first followers adopted their versification. The Iliad and Odyssey have much of the air of extempore compositions; an epithet is never wanting to fill up a verse; and a set of expressions are mechanically annexed to such ideas as were of frequent recurrence. Hence that copiousness and waste of words in the old Greek bard, which forms such a contrast to the condensed and laboured composition of Virgil.

The Greek prose was of a more difficult structure; and it may be distributed into different styles or degrees of purity. Of the prose authors now extant, the first and best style is that of Herodotus, and of Plato in the florid or mixed kind, of Xenophon in the pure and simple, of Thucydides and Demosthenes in the austere. Nothing, perhaps, is so conducive to form a good taste in composition as the study of these writers.

The style of Polybius forms a new epoch in the history of the Greek language: it was the idiotic or popular manner of expression, especially among military men, in his time, about the 150th Olympiad. It became the model of succeeding writers, by introducing a simple unstudied expression, and by emancipating them from the anxious labour of the old Greeks respecting the cadence and choice of words. The style of the New Testament, being plain and popular, frequently resembles that of Polybius, as has been shown by Raphelius, and by Kirchmaier, *de parallelismo*. N. T. *et Polybi*, 1725.

Before this historian, the Alexandrian Jews had formed a new or Hellenistic style, resulting from the expression of oriental ideas and idioms in Greek words, after that language had lost of its purity, as it gained in general use by the conquests of Alexander. The Hellenistic is the language of the Septuagint, the Apocrypha, the New Testament, and partly of Philo and Josephus. This mixture in the style of the evangelists and apostles, is one credential of the authenticity of the best of all books, a book which could not have been written but by Jewish authors in the first century. See the fine remarks of Bishop Warburton, *Doctrine of Grace*, book i. ch. 8—10. Critics lose their labour in attempting to adjust the Scripture-Greek to the standard of Atticism.

The diction of the Greek historians, and geographers of the Augustan age, is formed on that of Polybius; but improved and modernized, like the English of the present age, if compared by that of Clarendon or Bacon. More perspicuous than refined, it was well suited to such compilations as were then written by men of letters, such as Dionysius, Diodo-
rus,

Greek Language. rus and Strabo, without much experience or rank in public life.

The ecclesiastical style was cultivated in the Christian schools of Alexandria, Antioch, and Constantinople; rank and luxuriant, full of oriental idioms, and formed in a great measure on the Septuagint version. Such is, for instance, the style of Eusebius. After him, the best Christian writers polished their compositions in the schools of rhetoric under the later Sophists. Hence the popular and flowing purity of St Chrysostome, who has more good sense than Plato, and perhaps as many good words.

On the Greek of the Byzantine empire, there is a good dissertation by Ducange, *de causis corruptæ Græcicitatis*, prefixed to his Glossary, together with Portius's Grammar of the modern Greek. This last stage of the Greek language is a miserable picture of Turkish barbarism. And, which is most surprising, there is no city of Greece where the language is more different from the ancient than at Athens. The reason of that is, because it has been long inhabited by a mixed multitude of different nations.

To conclude, the Greeks have left the most durable monuments of human wisdom, fortitude, magnificence, and ingenuity, in their improvement of every art and science, and in the finest writings upon every subject necessary, profitable, elegant, or entertaining.

The Greeks have furnished the brightest examples of every virtue and accomplishment, natural or acquired, political, moral, or military: they excelled in mathematics and philology; in all the forms of government, in architecture, navigation, commerce, war: as orators, poets, and historians, they stand as yet unrivalled, and are like to stand so for ever; nor are they less to be admired for the exercises and amusements they invented, and brought to perfection, in the institution of their public games, their theatres, and sports.

180 No perfect translation of any Greek author. Let us further observe, that in vain our readers will look for these admired excellencies in any of the best translations from the Greek: they may indeed communicate some knowledge of what the originals contain; they may present you with propositions, characters, and events: but allowing them to be more faithful and more accurate than they really are, or can well be, still they are no better than copies, in which the spirit and lustre of the originals are almost totally lost. The mind may be instructed, but will not be enchanted: The picture may bear some faint resemblance, and if painted by a masterly hand give pleasure: but who would be satisfied with the canvas, when he may possess the real object? who would prefer a piece of coloured glass to a diamond? It is not possible to preserve the beauties of the original in a translation.—The powers of the Greek are vastly beyond those of any other tongue. Whatever the Greeks describe is always felt, and almost seen; motion and music are in every tone, and enthusiasm and enchantment possess the mind:

*Grævis ingenium, Grævis dedit ore rotundo,
Musa loqui.* Hor.

SECT. VIII. *Of the Latin Language.*

Latin Language.

This language, like every other spoken by barbarians, was in its beginning rough and uncultivated.—What people the Romans were, is a point in which antiquarians are not yet agreed. In their own opinion they were sprung from the Trojans*; Dion. Halicarn. derives them from the Greeks†; and Plutarch informs us‡ that some people imagined that they were sprung from the Pelasgi. The fact is, they were a mixture of people collected out of Latium and the adjacent parts, which a variety of accidents had drawn together, to establish themselves on that mountainous region, in order to secure their own property, and plunder that of their neighbours. They were in all probability composed of Arcadians, Sabinæ, Latins, Hetruscans, Umbrian, Oscans, Pelasgi, &c.; and if so, their language must have been a mixture of the different dialects peculiar to all these discordant tribes.

The Latin language ought then to be a mingled mass of the Arcadian, that is, the Æolian; Greek, the Pelasgic, Hetruscan, and Celtic dialects. These jarring elements, like the people to whom they belonged respectively, gradually incorporated, and produced what was afterwards called the *Latin tongue*.

The Arcadians were a Pelasgic‡ tribe, and consequently spoke a dialect of that ancient Greek produced by the coalition of this tribe with the savage aborigines of Greece. This dialect was the groundwork of the Latin. Every scholar allows, that the Æolian Greek, which was strongly tinged with the Pelasgic, was the model upon which the Latin language was formed. From this deduction it appears, that the Latin tongue is much more ancient than the modern Greek; and of course we may add, that the Greek, as it stood before it was thoroughly polished, bore a very near resemblance to that language. Hence we think we may conclude, that the knowledge of the Latin language is necessary in order to understand the Greek. Let us not then expect to find the real ingredients of the Greek tongue in the academic groves of Athens, or in Smyrna, or in Rhodope, or in Hæmos; but on the banks of the Tiber and on the fields of Laurentum.

A very considerable part of the Latin tongue was derived from the Hetruscan. That people were the masters of the Romans in every thing sacred. From them they learned the ceremonies of religion, the method of arranging games and public festivals, the art of divination, the interpretation of omens, the method of lustrations, expiations, &c. It would, we believe, be easy to prove, that the Pelasgi* and Hetrusci (x) were the same race of people; and if this was the case, their languages must have differed in dialect only.

The Umbrian or Celtic enters deeply into the composition of the Latin tongue. For proof of this, we need only appeal to *Pelloutier, Ballat's Nouvelles de la Langue Celtique, partie premiere, Abbé Pazzani's Origin*

12r Origin of the Romans, &c. of their language. * Tit. Liv. lib. 1. cap. 1. &c. † Antiqu. Rom. lib. 1. § Ver. &c. mul.

§ Strabo, lib. v. Deor. Hætern. Antiqu. lib. 1. || Strabo et Herodotus.

* Thucydides, lib. iv.

(x) The Hetrusci were variously denominated by the Greeks and Romans. The former called them *uscans*

Latin Language. of ancient Nations, &c. Whether the old Celtic differed essentially from the Pelasgic and Hetruscan, would be a matter of curious investigation, were this a proper subject for the present article.

The Latin abounds with oriental words, especially Hebrew, Chaldaic, and Persian. There are certainly remains of the Pelasgic and Hetruscan tongues, spoken originally by people who emigrated from regions where those were parts of the vernacular language.—The Greeks, in polishing their language, gradually distorted and disfigured vast numbers of the rough eastern vocables, which made a very great part of it. (See the preceding section).

The Romans, of less delicate organs, left them in their natural state, and their natural air readily betrays their original. We had collected a large list of Latin words still current in the east; but find that Thomassin * and Ogerius (y), and especially Monf. Gebelin, in his most excellent Latin Dictionary, have rendered that labour superfluous.

In this language, too, there are not a few Gothic terms. How these found their way into the Latin, it is not easy to discover, unless, as Pelloutier supposes, the Celtic and Gothic languages were originally the same: or perhaps we may conjecture, that such words were parts of a primitive language, which was at one time universal.

There are, besides, in the Latin a great number of obsolete Greek words, which were in process of time obliterated, and others substituted in their room; to that, upon the whole, we are persuaded, that the most effectual method to distinguish the difference between the early and modern Greek, would be to compare the ancient Latin with the latter; there being, we imagine, very little difference between the ancient Greek and Latin in the earliest periods.

However that may be, it is certain that the Roman letters were the same with the ancient Greek.—*Formæ literis Latinis quæ veterrimis Græcorum*, says Tacitus †; and Pliny ‡ says the same thing, and for the truth of his assertion he appeals to a monument extant in his own times.

These old Greek letters were no other than the Pelasgic, which we have shown from Diodorus Siculus (see preceding Section) to have been prior to the Cadmean. For the figure of these letters, see Atle, Postellus, Montfaucon, Palæographia Græca, Monf. Gebelin, and our Plates IX and X.

That the Latins borrowed the plan of their declensions from the Greeks, is evident from the exact resemblance of the terminations of the cases throughout the three similar declensions. In nouns of the first declension the resemblance is too palpable to stand in need of illustration. In the second, the Greek ge-

nitive is in *α*. In Latin the *ο* is thrown out, and the termination becomes *i*. In the Greek section, we have observed, that the sounds of *i* and *ο* differed very little; therefore the Latins used *i* instead of *ο*. The Latin dative ends in *ο*, which is the Greek dative, throwing away *ι* *subscriptum*, which was but faintly founded in that language. No genuine Greek word ended in *μ* or *ν*.

The Hellenes seemed to have abhorred that bellowing liquid; it is, however, certain that they imported it from the east, as well as the other letters, and that they employed it in every other capacity, except in that of closing words. In the termination of flexions, they changed it into *ν*.

The Latins retained *m*, which had been imported to them as a terminating letter at an era before the Greek language had undergone its last refinement.—Hence the Latin accusative in *um*, instead of the Greek *α*. The vocative case, we imagine, was in this declension originally like the nominative. The Latins have no dual number, because, in our opinion, the *Æ*lian dialect from which they copied, had none. It would be, we think, a violent stretch of etymological exertion, to derive either the Latin genitive plural of the second declension from the same case of the Greek, or that of the latter from the former; we therefore leave this anomaly, without pretending to account for its original formation. The third declensions in both languages are so exactly parallel, that it would be superfluous to compare them. The dative plural here is another anomaly, and we think a very disagreeable one, which we leave to the conjectures of more profound etymologists.

For the other peculiarities of Latin nouns, as they are nearly similar to those of the Greek, we must beg leave to remit our readers to that section for information.

The Latins have no articles, which is certainly a defect in their language. The Pelasgic, from which they copied, had not adopted that word in the demonstrative sense. Homer indeed seldom uses it; and the probability is, that the more early Greek used it less frequently, at least in the sense above-mentioned. Thus in Latin, when I say, *video hominem*, it is impossible to find out by the bare words whether the word *hominem* intimates “a man,” or “the man;” whereas in Greek it would be *Βλεπω ανθρωπον*, I see a man, *Βλεπω τον ανθρωπον*, I see the man. Hence the first expression is indefinite, and the second definite.

The substantive verb *sum* in Latin seems to be partly formed from the Greek and partly not. Some of the persons of the present tense have a near resemblance to the Greek verb *εω* or *ειμι*, while others vary widely from that archetype. The imperfect præterite and

* Glossary.

Latin Language.

183
Deficiency of articles.

184
Origin of the substantive verb.

τηρονοια; which was their true name, for they actually emigrated from Tarsish, or the western coast of Asia Minor, and consequently Herodotus everywhere calls them *τηρονοια*. The Æolians changed *α* into *ο*; hence in that dialect they were called *τηρονοια*, from *Tarsus*. The Romans styled them *Tusci*, probably from the Greek verb *θεω*, *τηρονοια*, alluding to the skill which that people professed in the ceremonies of religion. They called their country *Hetruria*, we think from the Chaldaic word *herutum*, “a magician or forcerer;” a name deduced from their skill in divination.

(y) *Græca et Latina lingua Hebraizantes*, Venice, 1763. If these books are not at hand, Dr Littleton's Dictionary will, in a good measure, supply their place.

Latin and præterperfect have nothing common with the Greek verb, and cannot, we think, be forced into an alliance with it. The future *ero* was of old *ēso*, and is indeed genuine Greek. Upon the whole, in our apprehension the Latin substantive verb more nearly resembles the Persian verb *hassen* than that of any other language we are acquainted with.

185
And of other verbs

From what exemplar the Latin verbs were derived, is not, we think, easily ascertained. We know that attempts have been made to deduce them all from the Æolic Greek, and that the Romans themselves were extremely fond of this chimera; but the almost numberless irregularities, both in the formation and conjugation of their verbs, induce us to believe that only a part of them were formed upon that model. We are apt to think that the terminations in *bam, las, bat, bamus*, &c. are produced by their union with a fragment of some obsolete verb, which is now wholly lost. In the verb *amo*, e. g. we are sure that the radix *am* is the Hebrew word *mother*; but how *am alan, am alo, am arem* were fabricated, and connected with the radical *am*, is not so easily determined. That Latin verbs are composed of an inflexible radix and another flexible verb, as well as the Greek, cannot be doubted, but what this flexible auxiliary was, we think, cannot now be clearly ascertained. It is not altogether improbable that such parts of the verbs as deviate from the Greek archetype were supplied by fragments of the verb *ha*, which pervades all the branches of the Gothic language, and has, we think, produced the Latin verb *habeo*. When the Greeks began to etymologize, they seldom overpassed the verge of their own language: the Latins pursued nearly the same course. If their own language presented a plausible etymology, they embraced it; if not, they immediately had recourse to the Greek; and this was the *ne plus ultra* of their etymological researches. Cicero, Quintilian, Festus, &c. and even Varro, and most of all the learned Romans, stop here; all beyond is either doubt or impenetrable darkness. The opinion abovementioned we offer only as a conjecture; the decision we leave to more able critics.

186
Deficiencies in Latin verbs.

The want of aorists or indefinite tenses seems to us a palpable defect in the Latin language. The use of these among the Greek enabled the writer to express the specific variations of time with more accuracy and precision than the Latins, who never attempted to specify them by any other tenses but the imperfect and pluperfect. Indeed we should imagine, that both the Greeks and Latins were much inferior to the English in this respect. The Latin word *lego*, for example, may be translated into English three different ways: 1st, *I read*; 2d, *I do read*; 3d, *I am reading*.

187
Irregularities in the conjugations.

The Latins, in reducing verbs to their four conjugations, formed their inflexions in a very irregular manner. Many verbs of the first class inflect their præterite and supine like those of the second: thus *domo*, instead of giving *avi* and *atum*, has *vi* and *itum*, like *veni* and *monitum*. Again, not a few verbs of the third conjugation have *ivi* and *itum*, as if they belonged to the fourth; e. g. *peto, petivi, petitum*. Then, some verbs have *io* in the present, *ivi* in the præterite, and *itum* in the supine, while, contrary to the rules of analogy, they in reality belong to the third: such are *cupio, cupivi, cupitum, cupere*, &c. Some verbs of the

second conjugation have their præterite and supine, if they belonged to the third; thus, *juvo, juvi, juitum, judera; augeo, auxi, auxum, augete*. Some verbs, which are actually of the fourth conjugation, have their præterite and supine as if they were of the third; thus, *sentio, sensi, sensitum, sentire; haurio, hauri, hauritum, haurire*, &c. If these are not manifest irregularities, we cannot say what deserves the name. The fact seems to stand thus: The Romans were originally a banditti of robbers, bankrupts, runaway slaves, flatterers, husbandmen, and peasants, of the most unpolished character. They were engaged in perpetual broils and quarrels at home, and seldom enjoyed repose abroad. Their profession was robbery and plunder. Like old Ishmael, their hands were against every man, and every man's hand against them. In such a state of society no time was left for cultivating the sciences. Accordingly the arts of war and government were their sole profession. This is so true, that their own poet characterizes them in the following manner:

Excubant aësi spiritibus molibus æra, &c.

188
The Latin deficient participles.

Another blemish in the Latin tongue is occasioned by its wanting a participle of the præterite tense in the active voice. This defect is perpetually felt, and is the cause of an awkward circumlocution wherever it happens to present itself. Thus, "The general having crossed the river drew up his army;" *Imperator, cum transisset flumen, aciem instruxit*. Here *cum transisset flumen* is a manifest circumlocution, which is at once avoided in the Greek *ὁ ἡγεμὼν περὶ τοῦ ποταμοῦ*, &c. This must always prove an incumbrance in the case of active intransitive verbs. When active deponent verbs occur, it is easily avoided. Thus, "Cæsar having encouraged the soldiers, gave the signal for joining battle;" *Cæsar cohortatus milites, prælii committendi signum dedit*.

Another palpable defect in this language arises from the want of a participle of the present passive. This again must produce an inconveniency upon many occasions, as will be obvious to every Latin student almost every moment.

189
Supines and gerunds.

The two supines are universally allowed to be substantive-nouns of the fourth declension. How these assumed the nature of verbs it is not easy to determine. When they are placed after verbs or nouns, the matter is attended with no difficulty; but how they should acquire an active signification, and take the case of the verb with which they are connected, implies, we should think, a stretch of prerogative.

The Latin gerunds form another unnatural anomaly. Every Latin scholar knows that these words are nothing but the neuters of the participles of the future passive. The fabricators of the Latin tongue, however, elevated them from their primary condition, giving them upon many occasions an active signification. In this case we must have recourse to

*Sic voluit usus,
Quem penes arbitrium est et jus et norma loquendi.*

Another inconveniency, perhaps more severely felt than any of the preceding, arises from the want of the use of the present participle of the verb *sum*. Every body knows what a conveniency is derived from the frequent use of the participle *ω* in Greek; and indeed it appears to us somewhat surprising that the

Latin
Language.

Latins neglected to introduce the participle *ens* into their language. In this we believe they are singular. Here again a circumlocution becomes necessary in such a case as the following: "The senate being at Rome, passed a decree." Instead of saying *senatus ens Rome*, *legis tulit*, we are obliged to say *cum senatus Rome esset*, &c. If the words *ens* or *existens* had been adopted, as in the Greek, this odious circumlocution would have been avoided.

Many other defects of the like kind will occur to every person who shall choose to search for them, and those in the most approved classical authors. Perhaps our mentioning so many may be deemed invidious by the admirers of that language; but we write from conviction, and that must be our apology.

195
Different
genius of
the Latin
and Greek
languages.

If one take the trouble to compare the structure of the Greek and Latin languages, he will, we think, quickly be convinced that their characteristic features are extremely different. The genius of the former seems easy and natural; whereas that of the latter, notwithstanding the united efforts of poets, orators, and philosophers, still bears the marks of violence and restraint. Hence it appears that the Latin language was pressed into the service, and compelled almost against its will to bend to the laws of the Grecian model. Take a sentence of Hebrew, Chaldean, Arabian, &c. and try to translate it into Greek without regarding the arrangement of the words, and you will find it no difficult attempt; but make the same trial with respect to the Latin, and you will probably find the labour attended with considerable difficulty. To translate Greek into English is no laborious task; the texture of the two languages is so congenial, that the words and phrases, and even the idiomatic expressions, naturally slide into each other. With the Latin the case is quite otherwise; and before elegant English can be produced, one must deviate considerably from the original. Should we attempt to translate a piece of English into Greek, and at the same time into Latin, the translation of the former would be attended with much less difficulty than that of the latter, supposing the translator equally skilled in both languages.

197
Causes of
the dif-
ference.

This incongruity seems to spring from the following cause. Before any man of considerable abilities, either in the capacity of a poet, grammarian, or rhetorician, appeared at Rome, the language had acquired a strong and inflexible tone, too stubborn to be exactly moulded according to the Grecian standard. After a language has continued several centuries without receiving a new polish, it becomes like a full grown tree, incapable of being bent to the purpose of the mechanic. For this reason, it is highly probable, that the tongue in question could not be forced into a complete assimilation with the Greek. Notwithstanding all these obstructions, in process of time it arrived at such an exalted pitch of perfection, as to rival, perhaps to excel, all the other European languages, the Greek only excepted. Had men of the taste, judgment, and industry of Ennius, Plautus, Terence, Cæcilius, and the worthies of the Augustan age, appeared in the early

stages of the Roman commonwealth, we may believe that their language would have been thoroughly reduced to the Grecian archetype, and that the two dialects might have improved each other by a rivalry between the nations who employed them.

Latin
Language.

Without pretending to entertain our readers with a pompous and elaborate account of the beauties of that imperial language which have been detailed by writers almost without number, we shall endeavour to lay before them as briefly as possible its pristine character, the steps and stages by which it gradually rose to perfection, the period when it arrived at the summit of its excellence; and by what means it degenerated with a rapid career till it was lost among these very people to whom it owed its birth.

We have observed already, that the Latin language was a *colluvies* of all the languages spoken by the vagrant people who composed the first elements of that republic. The prevailing dialects were the Pelasgic or Hetruscan, which we think were the same; and the Celtic, which was the aboriginal tongue of Italy. Hence the primary dialect of the Romans was composed of discordant materials, which in our opinion never acquired a natural and congenial union. Be that as it may, this motley mixture was certainly the original dialect of the Romans. The Pelasgic or Hetruscan part of it retained a strong tincture of the oriental style. The Celtic part seems to have been prevalent, since we find that most of the names of places (*z*), especially in the middle and northern parts of Italy, are actually of Celtic original. It is therefore clear that the style of the first Romans was composed of the languages above-mentioned. Who those first Romans were, we believe it is impossible to determine with any degree of certainty. The Roman historians afford us a little information upon that subject, as their etymologists do upon the origin of their language. Their most celebrated writers upon this point were Ælius Gallus, Quintus Cornificius, Nonius Marcellus, Festus, and some others of less note. At the head of these we ought to place Terentius Varro, whom Cicero styles the most learned of all the Romans. From these writers we are to expect no light. Their etymologies are generally childish and futile. Of the language of the most ancient Romans we can only reason by analogy; and by that rule we can discover nothing more than what we have advanced above.

192
The Latin
tongue
composed
chiefly of
Pelasgic
and Celtic
words.

In the first place we may rest assured that the dual number, the articles, the participle above-mentioned, the accents, and the whole middle voice, never appeared in the Latin tongue; and accordingly were not current in those languages from which it was copied, at least at the time when it was first fabricated.

Besides all this, many circumstances concur to make it highly probable that, in the earliest periods of the language, very few inflexions were introduced. 1st, When the Pelasgi left Greece, the Greek language itself was not fully polished. 2d, The Arcadians were never thoroughly cultivated. They were a rustic pastoral people, and little minded the refinements of a civilized

(z) For proof of this our readers may consult Abbe Pezron, Pelloutier, Bullet's *Mém. Gebelin Prof. Diss. Lat.* and many others.

Latin Language. Dion. Halicar. lib. 1.

vilized state; consequently the language they brought into Italy at that era must have been of a coarse and irregular texture. 3d, When the Thessalian Pelasgi arrived in Italy about the time of Demetrius, the Greek itself was rude and barbarous; and, which is still of more consequence, if we may credit Herodotus quoted in the former section, that people had never adopted the Hellenic tongue. Hence it appears, that the part of the Latin language derived from the Pelasgic or Hetruscan (for those we believe to have been the same) must have taken a deep tincture from the oriental tongues (see preceding Section). If we may judge of the Celtic of that age by that of the present, the same character must likewise have distinguished its structure

193 Hence little indebted in its original state.

From these circumstances, we think it appears that the earliest language of the Romans was very little diversified with inflections. It nearly resembled the oriental exemplar, and consequently differed widely from the modern Latin. The effect of this was, that the modern Romans could not understand the language of their early progenitors. Polybius*, speaking of the earliest treaty between the Romans and Carthaginians, makes the following observation: "Believe me (says he), the Roman language has undergone so many changes since that time (A) to the present, that even those who are most deeply skilled in the science of antiquities cannot understand the words of that treaty but with the greatest difficulty."

* Lib. 3. sub initio.

From this source we make no doubt has flowed that vast number of oriental words with which the Latin language is impregnated. These were originally inflexible, like their brethren of the east. They were not distinguished as they now are with prefixes, suffixes, metapheses, syncopas, antitheses, &c. but plain and adorned in their natural dress.

194 Sent afterwards into the Grecian model.

After the Romans became acquainted with the Æolian Greeks, who gradually fixed up in both coasts of Italy towards the south, which they called *Magna Græcia*, they began to admit a Grecian air, and to torture their language into that foreign texture. It appears, however, that at first the Grecian garb sat rather awkwardly, and several marks of violence were easily discerned. The most ancient specimen of this kind that we can recollect consists of the remains of the *twelve tables*. Here every thing is rude and of a clumsy cast; for though by this time considerable progress had been made in refinement, and the language of Rome had begun to appear in a Grecian uniform, still these changes were not altogether natural. Soon after appeared Marcus Fabius Pictor and Sisenna: historians often quoted by Livy, but whose works are long since irrecoverably lost. The *Fasti Capitolini* are often mentioned; but they too perished in the burning of the Capitol during the civil wars between Marius and Sulla. Had these monuments escaped the ravages of time, we should have been able to mark the progress of the Latin tongue from stage to stage, and to ascertain with the greatest accuracy its gradual configuration in the course of its progress towards the Grecian

standard. We must therefore believe the Latin to have during those periods rude and barbarous, and different to others better known and more distinguishedly marked. Those commenced after that

Græci cepta ferunt videmus. p. et art. Intulit agresti Latine.

In this period we find Ennius, who wrote a Roman history in hexameter verse in 18 books, which he called *Annales*; most part of which is now lost. His language was translated *Euhemerus de Origine Deorum*; a work often mentioned by the Christian fathers in their disputes with the Pagans. It is six times quoted by Cicero. Then followed Caius Lucilius the famous satirist, and a number of other writers, such as Accius, Valerius, Æditiuus, Alpinus, &c. whose fragments were published by the Stephens, Paris, 1564. All these imitated the writers of Greece or translated from them. By their perseverance and active exertions the spirit of these authors was transfused into the Latin tongue, and its structure accommodated to the Grecian plan.

Plautus and Terence, by translating the comedies of Menander and Diphilus into their own language, taught the Latin natives to speak Attic Greek. To speak that language was then the *ton* of the times, as it is now with us to chatter French. Greek tutors were retained in every reputable family; and many Romans of the first rank were equally qualified to speak or write both in Greek and Latin. The original jargon or Latium was now become obsolete and unintelligible; and Cato the Ancient condescended to learn the Greek language at 80.

To pretend to enumerate the various, and we may add inimitable, examples of the Augustan or golden age of the Roman tongue, would be an insult to the understanding of our readers: we shall only take the liberty to translate a few lines from a most excellent historian*, who, had his honesty been equal to his judgment, might have rivalled the most celebrated writers of his country. Having observed, that the Greek authors, who excelled in every province of literature, had all made their appearance nearly about the same space of time, confined within very narrow limits, he adds, "Nor was this circumstance more conspicuous among the Greeks than among the Romans; for unless we go back to the rough and unpolished times, which deserve commendation only on account of their invention, the Roman tragedy is confined to Accius and the period when he flourished. The charming work of Latin elegance was brought to light by Cælius, Terentius, and Asinius, nearly in the same age. As for our historians (to add Livy also to the age of the former), if we except Cato and some old obscure ones, they were all confined to a period of 85 years; so neither has our stock of poets extended to a space much backward or forward. But the energy of the bar, and the finished beauty of prose eloquence, sitting aside the same Cato (by leave of P. Crassus, Scipio, Lælius, the Græchi, Fannius, and Ser. Galba, be it spoken), broke out all at once under Tully the prince of

Latin Language

his profession; so that one can be delighted with none but him, and admire none except such as have either seen or were seen by that orator."

197 Causes of the degeneracy of the Latin tongue.

From this quotation it plainly appears, that the Romans themselves were convinced of the short duration of the golden age of their language. According to the most judicious critics, it commenced with the era of Cicero's oratorical productions, and terminated with the reign of Tiberius, or perhaps it did not reach beyond the middle of that prince's reign. It is generally believed that eloquence, and with it every thing liberal, elevated, and manly, was banished Rome by the despotism of the Cæsar. We imagine that the transition was too instantaneous to have been entirely produced by that unhappy cause. Despotism was firmly established among the Romans about the middle of the reign of Augustus; and yet that period produced such a group of learned men as never adorned any other nation in so short a space of time. Despotism, we acknowledge, might have affected the eloquence of the bar; the noble and important objects which had animated the republican orators being now no more; but this circumstance could not affect poetry, history, philosophy, &c. The style employed upon these subjects did not feel the fetters of despotism. The age of Louis XIV. was the golden period of the French tongue; and we think that age produced a race of learned men, in every department superior in number and equal in genius to the literati who flourished under the noble and envied constitution of Britain during the same age, though the latter is universally allowed to have been the golden period of this country. The British itself, we hope, enjoy still as much liberty as ever; yet we believe few people will aver, that the writers of the present age are equal either in style or in genius to that noble group who flourished from the middle of the reign of Charles I. to the middle of the reign of George II. and here despotism is quite unconcerned.

In the east the same observation is confirmed. The Persians have long groaned under the Mohammedan yoke: and yet every oriental scholar will allow, that in that country, and under the most galling tyranny, the most amazing productions of taste, genius, and industry, that ever dignified human nature, have been exhibited. Under the Arabian caliphs, the successors of Mohammed, appeared writers of a most sublime genius, though never was despotism more cruelly exercised than under those fanatics. The revival of letters at the era of the reformation was chiefly promoted and cherished by petty despotical princes.

We cannot therefore be persuaded to agree, that the despotism of the Cæsars banished eloquence and learning from Rome. Longinus indeed has attributed this misfortune to that cause, and tells us, ἡρεσται περὶ τῆς ἐλευθερίας καὶ τῆς ἐπισημοσύνης τῶν Μεγαλοκράτων ἢ ΕΛΕΥΘΕΡΙΑ, &c. "It is liberty that is formed to nurse the sentiments of great geniuses, to push forward the propensity of contest, to inspire them with hopes, and the generous ambition of being the first in rank." When Longinus wrote this, he did not reflect that he himself was a striking instance of the unsoundness of his observation.

As to science, the fact is undoubtedly on the other side. That Seneca was superior to Cicero in philoso-

phy, cannot be reasonably contradicted. The latter had read, and actually abridged, the whole extent of Grecian philosophy: this displayed his reading rather than his learning. The former had addicted himself to the stoic sect; and though he does not write with the same flow of eloquence as Tully, he thinks more deeply and reasons more closely. Pliny's Natural History is a wonderful collection, and contains more useful knowledge than all the writings of the Augustan age condensed into one mass. We think the historical annals of Tacitus, if inferior to Livy in style and majesty of diction, much superior in arrangement and vigour of composition. In short, we discover in these productions a deep insight into human nature, an extensive knowledge of the science of government, a penetration which no dissimulation could escape, together with a sincere attachment to truth both with respect to events and characters; nor is he inferior in the majesty, energy, and propriety of his harangues, wherever an equal opportunity presents itself. Quintilian, Pliny the younger, Suetonius, Petronius Arbiter, and Juvenal, deserve high esteem; nor are they inferior to their immediate predecessors. We think there is good reason to conclude, that the loss of liberty among the Romans did not produce the extinction of eloquence, science, elevation of sentiment, or refinement of taste. There were, we believe, other circumstances which chiefly contributed to produce that revolution.

The same Velleius Paterculus whom we have quoted assigns some plausible and very judicious reasons for this catastrophe. "Emulation (says he) is the nurse of genius; and one while envy, and another admiration, fires imitation. According to the laws of nature, that which is pursued with the greatest ardour mounts to the top: but to be stationary in perfection is a difficult matter; and by the same analogy, that which cannot go forward goes backward. As at the outset we are animated to overtake those whom we deem before us, so when we despair of being able to overtake or to pass by them, our ardour languishes together with our hope, and what it cannot overtake it ceases to pursue; and leaving the subject as already engrossed by another, it looks out for a new one upon which to exert itself. That by which we find we are not able to acquire eminence we relinquish, and try to find out some object *elsewhere* upon which to employ our intellectual powers. The consequence is, that frequent and variable transitions from subject to subject prove a very great obstacle to perfection in any profession."

This perhaps was the case with the Romans. The heroes of the Augustan age had borne away the prize of eloquence, of history, of poetry, &c. Their successors despaired of being able to equal, much less to surpass them, in any of these walks. They were therefore laid under the necessity of striking out a new path by which they might arrive at eminence. Consequently Seneca introduced the *stile coupé*, as the French call it; that is, a short, sparkling, figurative diction, abounding with antitheses, quaintnesses, witticisms, embellished with flowers and metrical ornaments; whereas the style of the Augustan age was natural, simple, solid, unadorned, and properly adapted to the nature of the subject and the sentiments of the author.

The historian Sallust laid the foundation of the unnatural

Latin Language. 198 The writers of the silver age greater masters of science than their predecessors.

Latin Language. natural style above mentioned. Notwithstanding all the excellencies of that celebrated author, he every where exhibits an affectation of antiquity, an antithetical cast, an air of austerly, an accuracy, exactness, and regularity, contrary to that *air degagé* which nature displays in her most elaborate efforts. His words, his clauses, seem to be adjusted exactly according to number, weight, and measure, without excess or defect. Velleius Paterculus imitated this writer; and, as is generally the case with imitators, succeeded best in those points where his archetype had failed most egregiously. Tacitus, however excellent in other respects, deviated from the Augustan exemplars, and is thought to have imitated Sallust; but affecting brevity to excess, he often falls into obscurity. The other contemporary writers employ a cognate style; and because they have deviated from the Augustan standard, their works are held in less estimation, and are thought to bear about them marks of degeneracy.

That degeneracy, however, did not spring from the despotic government under which these authors lived, but from that affectation of singularity into which they were led by an eager but fruitless desire of signaling themselves in their mode, as their predecessors had done in theirs. But the mischiefs of this rage for innovation did not reach their sentiments as it had done their style; for in that point we think they were so far from falling below the measure of the writers of the former age, that in many instances they seem to have surpassed them.

With respect to sentiment and mental exertions, the authors in question preserved their vigour, till luxury and effeminacy, in consequence of power and opulence, enervated both the bodies and minds of the Romans. The contagion soon became universal; and a listlessness, or intellectual torpor, the usual concomitant of luxury, spread indolence over the mental faculties, which rendered them not only averse to, but even incapable of, industry and perseverance. This lethargic disposition of mind seems to have commenced towards the conclusion of the silver age; that is, about the end of the reign of Adrian. It was then that the Roman eagles began to sloop, and the genius of Rome, as well in arts as in arms, began to decline. Once more, the declension of the intellectual powers of the writers of that nation did not arise from the form of the government, but from the causes above specified.

As the Roman genius, about that period, began to decline, so the style of the silver age was gradually vitiated with barbarisms and exotic forms of speech. The multitudes of barbarians who flocked to Rome from all parts of the empire; the ambassadors of foreign princes, and often the princes themselves, with their attendants; the prodigious numbers of slaves who were entertained in all the considerable families of the capital, and over all Italy; the frequent commerce which the Roman armies upon the frontiers carried on with the barbarians; all concurred to vitiate the Latin tongue, and to interlard it with foreign words and idioms. In such circumstances, it was impossible for that or any other language to have continued pure and untainted.

This vitiated character both of style and sentiment became more and more prevalent, in proportion as it descended from the reign of Adrian towards the era

of the removal of the imperial seat from Rome to Constantinople. Then succeeded the Iron age, when the Roman Language became absolutely rude and barbarous.

Towards the close of the silver, and during the whole course of the brazen age, there appeared, however, many writers of no contemptible talents. The most remarkable was Seneca the stoic, the master of Nero, whose character both as a man and a writer is discussed with great accuracy by the noble author of the *Charactéristiques*, to whom we refer our readers.

About the same time lived Perius the Sityrill, the friend and disciple of the stoic Cornutus; to whose precepts, as he did honour by his virtuous life, so his works, though small, show an early proficiency in the science of morals.

Under the mild government of Adrian and the Antonines lived Aulus Gellius, or (as some call him) Agellius; an entertaining writer in the miscellaneous way, well skilled in criticism and antiquity. His works contain several valuable fragments of philosophy, which are indeed the most curious parts of them.

With Aulus Gellius we may range Macrobius; not because a contemporary (for he is supposed to have lived under Honorius and Theodosius), but from his near resemblance in the character of a writer. His works, like those of the other, are miscellaneous; filled with mythology and ancient literature, with some philosophy intermixed.

In the same age with Aulus Gellius flourished Apuleius of Madaura in Africa; a Platonic writer, whose matter in general far exceeds his perplexed and affected style, too conformable to the false rhetoric of the age when he lived.

Boethius was descended from one of the noblest of the Roman families, and was consul in the beginning of the sixth century. He wrote many philosophical works; but his ethic piece on the Consolation of Philosophy deserves great encomiums, both for the matter and the style; in which latter he approaches the purity of a far better age than his own. By command of Theodoric king of the Goths this great and good man suffered death; with whom the Latin tongue, and the last remains of the Roman dignity, may be said to have sunk in the western world.

There were besides a goodly number both of poets and historians who flourished during this period; such as Silius Italicus, Claudian, Ausonius, &c. poets and historians to a very great number, for whom our readers may consult *Job. Alberti Fabricii Bibl. Lat.*

There flourished, too, a number of ecclesiastical writers, some of whom deserve great commendation. The chief of these is Lactantius, who has been deservedly dignified with the title of the *Christian Cicerone*.

The Roman authors amount to a very small number in comparison of the Greek. At the same time, when we consider the extent and duration of the Roman empire, we are justly surpris'd to find so few writers of character and reputation in so vast a field. We think we have good reason to agree with the prince of Roman poets in the sentiment quoted p. 553.

Upon the whole, the Latin tongue deserves our attention beyond any other ancient one now extant. The grandeur of the people by whom it was spoken;

Latin Language.

the lustre of its writers; the empire which it still maintains among ourselves; the necessity we are under of learning it in order to obtain access to almost all the sciences, not even to the knowledge of our own laws, of our judicial proceedings, of our charters; all these circumstances, and many others too numerous to be detailed, render the acquisition of that imperial language in a peculiar manner at once improving and highly interesting. Spoken by the conquerors of the ancient nations, it partakes of all their revelations, and bears continually their impression. Strong and nervous while they were employed in nothing but battles and campaign, it thundered in the camp, and made the most valiant people to tremble, and the most despotic monarchs to read their fables and tricks to the people. Copious and majestic, when, weary of battles, the Romans inclined to vie with the Greeks in science and the graces, it became the learned language of Europe, and by it, in the made the jargon of savages disappear who disputed with it the possession of that quarter of the globe. After having controlled by its eloquence, and humanized by its laws, all those people, it became the language of religion. In short, the Latin language will be studied and esteemed as long as good sense and fine taste remain in the world.

SECT. IX. Celtic, Gothic, and Saxonian Languages.

§ 1. Of the Celtic Language.

IN treating of the origin of the Latin tongue (see Section VIII.), we observed that a great part of it is derived from the Celtic. We shall now endeavour to give some account of the origin and extent of that ancient language; still leaving the minutie to grammars and dictionaries, as we have done with respect to the other dialects which have fallen under our consideration. Our candid readers, it is hoped, will remember, that we are acting in the character of philologists, not in that of grammarians and lexicographers.

The descendants of Japhet having peopled the western parts of Asia, at length entered Europe. Some broke into that quarter of the globe by the north, others found means to cross the Danube near its mouth. Their posterity gradually ascended towards the source of that river; afterwards they advanced to the banks of the Rhine, which they passed, and thence spread themselves as far as the Alps and the Pyrenean hills.

These people, in all probability, were composed of different families; all, however, spoke the same language; their names and customs bore a near resemblance; there was no variety among them but that difference which climate always introduces. Accordingly they were all known, in the more early times, by the general name of *Celtæ* or *Galæ*. In process of time, becoming exceedingly numerous, they were divided into several nations, which were distinguished by different names and territorial appellations. Those who inhabited that large country bounded by the ocean, the Mediterranean, the Rhine, the Alps, and the Pyrenees, were denominated *Gauls* or *Celtæ*. Those people multiplied so prodigiously in the space of a few centuries, that the fertile regions which they then occupied could not afford them the means of subsistence. Some of them now passed over into Britain; others

crossed the Pyrenees, and formed settlements in the northern parts of Spain. Even the formidable barriers of the Alps could not impede the progress of the Gauls: they made their way into Italy, and colonized those parts which lie at the foot of the mountains; whence they extended themselves towards the centre of that rich country.

By this time the Greeks had landed on the eastern coasts of Italy, and founded numerous colonies in those parts. The two nations vying as it were with each other in populousness, and always planting colonies in the course of their progress, at length encountered about the middle of the country. This central region was at that time called *Latium*. Here the two nations formed one society, which was called the *Latin people*. Their languages of the two nations were blended together; and hence, according to some, the Latin is a mixture of Greek and Gaelic.

As the Gauls were a brave and numerous people, they certainly maintained themselves in their pristine freedom, uninvaded, unconquered, till their civil animosities and domestic quarrels exposed them as a prey to those very Romans whom they had so often defeated, and sometimes driven to the brink of destruction. They were not a people addicted to commerce; and, upon the whole, considering their situation both in their primary seats and afterwards in Italy, they had little temptation or opportunity to mingle with foreigners. Their language, therefore, must have remained unmingled with foreign idioms. Such as it was when they settled in Gaul, such it must have continued till the Roman conquests. If therefore there is one primitive language now existing, it must be found in the remains of the Gaelic or Celtic. It is not, then, surprising, that some very learned men, upon discovering the coincidence of very great numbers of words in some of the Greek dialects with other words in the Celtic, have been inclined to establish a strict affinity between those languages. The ancient Pelasgic and the Celtic at least must have nearly resembled each other, admitting a dialectical difference only, and that discrimination which climate and a long period of time must always produce.

204
Resemblance between their language and that of the Pelasgi.

Some have thought that the Gauls lost the use of their native language soon after their country was conquered by the Romans; but *Monsieur Bulet*, in his *Mémoires de la Langue Celtique*, has proved almost to a demonstration, that the vulgar among those people continued to speak it several centuries after that period. When a great and populous nation has for many ages employed a vernacular tongue, nothing can ever make them entirely relinquish the use of it, and adopt unmingled that of their conquerors.

Many learned men, among whom is the lexicographer above-mentioned, have shown that all the local names in the north of Italy are actually of Celtic extraction. These names generally point out or describe some circumstances relating to the nature of their situation; such as exposure, ornament, strength, moistness, dryness, coldness, heat, &c. This is a very characteristic feature of an original language, and in the Celtic it is so prominent, that the local names of places all over Scotland are even to this day, peculiarly distinguished by this quality. We have heard of a gentleman, who was well skilled in the dialect of the Celtic still spoken

in

222
Origin of the Celts,

225
Part of whom were denominated Gauls

Celtic Language.

in the Highlands of Scotland, propose to lay a bet, at very great odds, that if one should pronounce the name of any village, mountain, river, gentleman's seat, &c. in the old Scottish dialect, he should be able, by its very name, to give a pretty exact description of its local situation.

To discover the sources from which the Celtic tongue is derived we must have recourse to the following expedients.

1. We must consult the Greek and Latin authors, who have preserved some Gaelic or Celtic terms in their writings.

2. We must have recourse to the Welsh and *Breaghe* dialects; in which, indeed, there are many new words, but these are easily distinguished from the primitive stock.

3. If one would trace another source of the Celtic, he must converse with the country people and peasants, who live at a distance from cities, in those countries where it was once the vernacular tongue. We have been credibly informed, that a Highland gentleman, crossing the Alps for Italy, accidentally fell in with an old woman, a native of those parts, who spoke a language so near akin to his native Erse, that he could understand her with little difficulty; and that she, on the other hand, understood most of his words. That an event of this nature should actually take place is by no means surprising, when we consider that the Erse spoken in the Highlands of Scotland is perhaps the most genuine remnant of the Celtic now existing, and at the same time reflect that there may be some remote cantons among those wild and inaccessible mountains, the Alps, where some remains of that tongue may be still preserved.

205 The most genuine remains of the Celtic in the Highlands of Scotland.

4. We have said, that the most genuine remains of the Gaelic tongue are to be found in the Highlands of Scotland; and the reason is obvious. The Scottish Highlanders are the unmixed unconquered posterity of the ancient Britons, into whose barren domains the Romans never penetrated; not, we imagine, because they were not able, since they subdued both North and South Wales, equally inaccessible, but because they found no scenes there either to fire their ambition or allure their avarice. Amidst all the revolutions that from time to time shook and convulsed Albion, those mountainous regions were left to their primitive lords, who, like their Southern progenitors, hospitable in the extreme, did not, however, suffer strangers to reside long among them. Their language accordingly, remained unmixed, and continues so even to this day, especially in the most remote parts and unfrequented islands.

The Norwegians subdued the western islands of Scotland at a time when the Scottish monarchy was still in its minority. They erected a kind of principality over them, of which the title of *Man* was the capital. Though they maintained the sovereignty of those islands for some centuries, built many forts, and strengthened them with garrisons, and in fine were the lawgivers and administrators of justice among the natives; yet we have been informed by the most respectable authority, that there is not at this day a single vocable of the Norse or Danish tongue to be found among these islanders. This fact affords a demonstration of that superstitious attachment with which they were devoted to their vernacular dialects.

The Welsh dialect cannot, we think, be pure and unsophisticated. The *Sloares* were conquered by the Romans, to whom they were actually subject for the space of three centuries. During this period, a multitude of Italian exotics must have been transplanted into their language; and indeed many of them are still visible at this day. Their long commerce with their English neighbours and conquerors hath adulterated their language, so that a great part of it is now of an English complexion. The Irish are now spoken by a race of people whose morality and ingenuity are nearly upon a level. Their late Discoveries have brought them from the confines of Asia, through a variety of adventures, to people an island *extra annis silisque vias*. However this geographical title may please the people for whom it was fabricated, we must still suspect that the Irish are of Celtic extraction, and that their forefathers emigrated from the western coast of Britain at a period prior to all historical or even traditional annals. Ireland was once the *native land of saints*. The chief actors on this sacred stage were Romanists, and deeply tinged with the superstition of the times. They pretended to improve the language of the natives; and whatever their success was, they improved it in such a manner as to make it deviate very considerably from the original Celtic; so that it is not in Ireland that we are to look for the genuine characters of the dialect under consideration.

Celtic Language. 206 The Welsh dialect not the Irish

Though the Hibernian tongue, in our opinion, differs considerably from the original Celtic, some very ingenious essays have been lately published by the learned and laborious members of the *Antiquarian Society of Dublin*; in which the coincidence of that tongue, with some of the original dialects, has been supported by very plausible arguments. In a dissertation published in the year 1772, they have exhibited a collection of *Punic Maltese* words compared with words of the same import in Irish, where it must be allowed the resemblance is palpable. In the same dissertation they have compared the celebrated *Punic scene* in Plautus with its translation into the Irish; in which the words in the two languages are surprisingly similar. If those criticisms are well founded, they will prove that the Celtic is coeval and congenial with the most ancient languages of the east; which we think highly probable. Be that as it may, the Danes and Norwegians formed settlements in Ireland; and the English have long been sovereigns of that island. These circumstances must have affected the vernacular idiom of the natives; not to mention the necessity of adopting the language of the conquerors in law, in sciences, and in the offices of religion.

207 Coincidence between the Celtic and Punic

The inhabitants of the Highlands and islands of Scotland are the descendants of those Britons who fled from the power of the Romans, and sheltered themselves among the fens, rocks, and fastnesses of those rugged mountains and sequestered gylms. They preferred these wastes and wilds, with liberty and independence, to the pleasant and fertile valleys of the south, with plenty embittered by slavery. They no doubt carried the language along with them; that language was a branch of the Celtic. With them, no doubt, fled a number of the didactical priests, who unquestionably knew their native dialect in all its beauties.

Celtic
Language.

and varieties. These fugitives in process of time formed a regular government, elected a king, and became a considerable state. They were sequestered by their situation from the rest of the world. Without commerce, without agriculture, without the mechanical arts, and without objects of ambition or emulation, they addicted themselves wholly to the pastoral life as their business, and to hunting and fishing as their diversion. Those people were not distinguished by an innovating genius; and consequently their language must have remained in the same state in which they received it from their ancestors. They received it genuine *Celtic*, and such they preserved it.

When the Scots became masters of the low country, and their kings and a great part of the nobility embraced the Saxon manners, and adopted the Saxon language, the genuine Caledonians tenaciously retained their native tongue, dress, manners, customs, and feudal customs, and could never cordially assimilate with their southern neighbours. Their language, therefore, could not be polluted with words or idioms borrowed from a people whom they hated and despised. Indeed it is plain from the whole tenor of the Scottish history, that neither Caledonian chieftains, nor their vassals, were ever steadily attached to the royal family after they fixed their residence in the low country, and became *Saxons*, as the Highlanders called them by way of reproach. Indeed the commerce between them and those of the south, till about a century and a half ago, was only transient and accidental; nor was their native dialect in the least affected by it.

Their language, however, did not degenerate, because there existed among them a description of men whose profession obliged them to guard against that misfortune. Every chieftain retained in his family a bard or poet laureat, whose province it was to compose poems in honour of his lord, to commemorate the glorious exploits of his ancestors, to record the genealogy and connections of the family; in a word, to amuse and entertain the chief and his guests at all public entertainments and upon all solemn occasions. Those professors of the Parnassian art used to vie with each other; and the chiefs of families often assembled their respective bards, and encouraged them by considerable premiums to exert their poetic talents. The victor was rewarded and honoured; and the chieftain deemed it an honour to himself to entertain a bard who excelled his peers. The ancient Gauls, as we learn from Diodorus Siculus, Strabo, Tacitus, Lucan, &c. entertained persons of that profession; and certainly the ancient Britons did the same. Those bards were highly revered; their persons were deemed sacred; and they were always rewarded with salaries in lands or cattle (See section *Gaelic*.) Those poetic geniuses must have watched over their vernacular dialect with the greatest care and anxiety; because in their compositions no word was to be lost, but as many gained as possible.

The use of letters was not known among the ancient *Celts*; their credulous clergy forbade the use of them. All their religious rites, their philosophical dogmas, their moral precepts, and their political maxims, were composed in verses which their pupils were obliged to commit to memory. Accordingly letters

were unknown to the Caledonian Scots, till they learned them either from their southern neighbours or from the Romans. The Irish, indeed, pretend to have letters of a very ancient date; the Highlanders of the country in question make no claim to the use of that invention. Their bard, therefore, committed every thing to memory; and of course the words of their language must have been faithfully preserved. We find that the celebrated poems of O'Flann, and others of an inferior character, or at least fragments of such poems (see *Ossian*), have thus been preserved from father to son for more than 1000 years. The beauty, significance, harmony, variety, and energy of these verses, strike us even in a prose translation: how infinitely more charming must they appear in their native form and poetical attire!

In order to exhibit the genius of the Celtic in as striking a light as the nature of our present design will permit, we shall lay before our readers a very contracted sketch of the Gaelic or Caledonian dialect as it now stands; which we hope will go a great way to convince them that this is the genuine offspring of the other. In doing this we shall borrow many hints from a gentleman* whose learning seems to equal his zeal for his native language; which, in compliance with the modern practice, we shall for the future distinguish by the name of *Gaelic*.

The Gaelic is not derived from any other language as far as we know, being obviously reducible to its own roots. Its combinations are formed of simple words of a known signification; and those words are resolvable into the simplest combinations of vowels and consonants, and even into simple sounds. In such a language we may expect that its traces will be found of the ideas and notions of mankind living in a state of primeval simplicity; and if so, a monument is still preserved of the primitive manners of the Celtic race while as yet under the guidance of simple nature, without any artificial restraint or controul.

The sudden sensations of heat and cold, and bodily pain, are expressed by articulate sounds, which, however, are not used in this language to denote heat, cold, or bodily pain. A sudden sensation of heat is denoted by an articulate exclamation *hait*; of cold, by *id*; of bodily pain, by *oich*. All these sounds may be called *interjections*, being parts of speech which discover the mind to be seized with some passion. Few of the improved languages of Europe present so great a variety of sounds which instantaneously convey notice of a particular passion, bodily or mental feeling.

The pronouns *he* and *she* are expressed by the simple sounds *e* and *i*, and these are the marks of the masculine and feminine genders; for a neuter gender is unknown in the *Gaelic*. The compositions of rude and barbarous ages are universally found to approach to the style and numbers of poetry; and this too is a distinguishing character of the *Gaelic*. Bodily subsistence will always be the principal concern of an uncultivated people. Hence *ed* or *id* is used upon discovery of any animal of prey or game: it is meant to give notice to the hunting companion to be in readiness to seize the animal; and hence we believe *ed* "to eat" in Latin, and *ed* in Irish signifies "cattle;" likewise in Scotch *adal* "cattle," literally signifies

"the

Celtic Language. "the offspring or generation of cattle." *Cow* or *cud*, "share or proportion of any subject of property," literally "common food." *Pack* "hunting;" literally "gathering of food." *Edra* "the time of the morning when cattle are brought home from pasture to give milk;" literally "meal-time." These are words importing the simplicity of a primitive state, and are common in the Gaelic idiom.

Traces of imitative language remain in all countries. The word used for *coco* in the Gaelic language is *bo*, plainly in imitation of the lowing of that animal.

In joining together original roots in the progress of improving language and rendering it more copious, its combinations discover an admirable justness and precision of thought, which one would scarce expect to find in an uncultivated dialect. It will, however, be found, upon examination, that the Gaelic language, in its combination of words, specifies with accuracy the known qualities, and expresses with precision the nature and properties which were attributed to the object denominated.

209
Excellency
of Gaelic
compounds

An appears to have been a word of frequent use in this language, and seems to have been originally a name applied indefinitely to any object. According to *Bulle*, it was used to signify "a planet;" hence the *sun* had the name of *grian*, which is a compound of *gri* "hot," and *an* "a planet." *Re* signifies originally and radically "division." The changes of the moon and the variety of her phases were early employed to point out the divisions of time. The present name for the moon is *gealach*; a word derived from her whiteness of colour. To these we might add a vast number more whose signification precisely indicates their shape, colour, effects, &c. Many of these would be found exactly similar to Greek and Latin words of the same found and signification. In order to satisfy our curious readers, we shall annex a few, though some of them may perhaps be questionable.

The *Venus* of the Latins is said to be a compound of *ben* and *jus*, which literally signify "the first woman," the letter *b* in Gaelic being softened into *v*. *Edap* and *udap* signify "food." These words are compounded of the Gaelic words *ed* or *id* and *ar*; the former denotes *food* simply, and the latter *ploughed land*. These are the roots of the Greek and Latin words *ισω εδο*, *αρω αρο*. *Edra*, which signifies "a feat," has an evident reference to food. It is compounded of two Gaelic words *ed* and *ira*, which literally signify "meal-time." *Edyr*, which signifies "the presents which a bridegroom made to his bride," is a compound of two Gaelic words *ed* and *na* or *nuch*, literally signifying "raw food." From *ar* there are many Greek derivatives. *Αρρα* signifies "ploughed land," also "crop of corn;" *Αρτος* "bread." In Gaelic a *crop of corn and bread* are expressed by *aribar*, commonly pronounced *arar* and *aran*; all being equally derivatives of the root *ar*. So the Greek and Latin words *αριτος*, *arabilis*, "arable;" *αριτρον*, *aratrum*, "a plough;" *αροστη*, *arator*, "a ploughman;" and many others, are evidently derived from the same source. We would not, however, suggest, in consequence of this coincidence, that either the Greek or Latin lan-

VOL. XIV.

guages were derived from the Gaelic; we rather believe that these are remains of a primeval tongue, which are still retained in all the three; and we produce them upon the present occasion as presumptions that the Gaelic is an original, undeviated language, and of course the most pure and unadulterated relic of the Celtic now existing. If our readers should incline to know more of this subject, they may consult *Perizon's Origin of Ancient Nations*, *Bullet's Mem. de la Langue Celtique*, *Parson's Rem. of Japhet*, *Cebelin, Munk's prim.* &c.

Celtic
Language

When the Celtic language was generally spoken over Europe, it seems to have been amazingly copious. By consulting *Bullet's Memoires*, it appears that its names for the common and various objects of nature were very numerous. The words denoting water, river, wood, forest, mountain, lake, &c. were most precisely accommodated to specify each modification and variety, with such peculiar exactness as even the Greek, with all its boasted idiomatical precision and copiousness, has not been able to equal. The appearances which diversify the visible face of inanimate nature, arrest the attention of men in an uncultivated state. Unaccustomed to thought and abstract reasoning, their minds expand and exercise their powers upon sensible objects, and of course mark every *minutia* and almost imperceptible distinction with an accuracy to us seemingly impossible.

213
Copious-
ness and
antiquity
of the Cel-
tic.

We hope it now appears to every reader, that the Celtic was one of the dialects of the primitive language; that it once overspread by far the greatest part of Europe; that the Gaelic now spoken in the northern parts of Scotland and the adjacent islands is the most pure and unmixed relic of that tongue now anywhere existing. We would willingly refer our readers to some well composed grammar of that language; but indeed we know of none that deserves our recommendation. Some years ago we were flattered with the prospect of seeing one published by a gentleman whose deep skill in that language is universally acknowledged. We have likewise heard of an intended dictionary of the same tongue; but hitherto our hopes have been disappointed.

We are, however, happy to find that there is now publishing an excellent translation of both the Old and New Testaments into Gaelic, which has hitherto been a desideratum among those who speak this language. Such a translation will at once contribute to preserve that ancient tongue, and disseminate the knowledge of the truth among the natives of that country.

Every assistance towards acquiring the knowledge of a tongue which was once universal over a great part of Europe, will certainly be an acceptable present to the public. The antiquary, who is desirous of tracing the affinity of languages, and wishes to mark the migrations of people, ought certainly to apply himself to the study of its remaining branches; and, if we mistake not, he will soon be convinced, that they all breathe a spirit congenial to the manners and sentiments of a people who are just entering upon the first stage of improvement and civilization.

Perhaps it may be expected, that, before we con-

211
Origin of
the words
Gaul and
give Gal.

Celtic
Language.

give some account of the origin of the words *Gaul* and *Gal*, the two names by which this people was distinguished by the Greeks and Romans. Mr M'Pherson imagines, that the appellation of *Celt* is an adjective derived from *Gael*, the aboriginal name of the inhabitants of ancient Gaul. For our part, we can see no connection between *Gael* and *Kelt*, nor do we think that the latter is an adjective. We believe that those people called themselves *Cæl* and not *Gael*. We are sure that *Caledonia*, or *Cal-don* or *dun*, was an ancient name of the mountainous parts of Scotland.

Though many different opinions have been advanced with relation to the etymology of this word, we imagine that none is so probable as that which supposes that it is compounded of the two Celtic words *Cal* or *Kal*, that is, "Gal or Gaul," and *dun*, which signifies "a hill or mountain." Upon this ground, the Caledonii will import the Gauls of the mountains, or, which is the same the Highland Gauls. The Irish and Highlanders reciprocally denominate themselves by the general title of *Cael*, *Gael*, or *Gaulr*. They also distinguish themselves, as the Welch originally did, and as the Welch distinguish them both at present, by the appellation of *Guilbill*, *Cuthel*, and *Gathel*. The intermediate *th*, they say, is left quiescent in the pronunciation, as it is in many words of the British language; in which case *Gathel* would immediately be formed into *Gael*; and *Gathel* is actually founded like *Gael* by both the Irish and Highlanders at present. The appellation of *Gathel*, therefore, say they, was originally the same with *Gael*, and the parent of it. The quiescent letters in British are frequently transferred from the middle to the conclusion of the word; by which manœuvre, *Gathel* is changed into *Galath*, *Galat*, *Galt*, and *Celt*. It is true, that *Gael* of the continent is universally denominated *Galatæ* and *Celtæ* by the Grecians, and *Gallt* and *Gallia* by the Irish. The appellations, therefore, of *Gathel-i*, *Gall-i*, *Gallat-æ*, *Calat-æ*, *An-calit-æ*, and *Celt-æ*, are all one and the same denomination, only varied by the astonishing ductility of the Celtic, and disguised by the alterations ever incident to a language that has been merely oral for ages.

It may perhaps appear presumptuous in us to differ from two such respectable authorities as M'Pherson and Whitaker: we must, however, acknowledge, that neither the one nor the other appears to us well founded. Besides, they convey no idea of the signification of the words, though in the celtic language they must have been significant. The name *Cæl*, the same with *Gal* was probably given them in the East from the Greek γαλ, which in many oriental languages denotes fair; and γαλατια may be easily derived from γαλ or γαλαθ, *Gal* or *Galath*.—This denomination might be given them by their neighbours, in allusion, to their fair complexion.

§ 2. Of the Gothic Language.

THE Celtic and Gothic tongues at one time divided

Europe between them. Both were of equal antiquity, both originated in Asia, both were dialects of the original language of mankind. The Celtic, however, was first imported into Europe. The Gauls or Celts had penetrated furthest towards the west; a circumstance which plainly intimates the priority of their arrival. In the population of countries, we believe it may be held as a maxim, that the colonies who emigrated first were generally impelled by succeeding emigrants; and that of consequence the most early were pushed forward to the parts most distant. The Celts, then, having overspread the most western parts of Europe, must have arrived more early in those regions.

The Goths and Getæ were the same race of people, according to Procopius², *de bello Goth.*; and Strabo³ (B) informs us, that they spoke the same language with the Thracians, from whose confines they had spread themselves northward as far as the western banks of the Danube. Vopiscus, in the History of Probus, tells us, that this emperor⁴ obliged "the Thracians, and all the Getic tribes, either to surrender or accept of his friendship." This expression indicates, that the Thracians and the Getic tribes were deemed the same race of people. From this deduction it is clear, that the Getæ and Thracians were brethren; that they spoke the same language: and that their laws, manners, customs, and religious tenets, were the same, might easily be shown, were this a proper place for an inquiry of that nature.

The Thracian language, as might be demonstrated from names of persons, offices, places, and customs, among that people, was nearly related to the Chaldean and other oriental languages.

They are thought to have been the descendants of Tiras, one of the sons of Japhet, and consequently must have preserved the speech of the Noachic family. The Gothic language abounds with *Pahlavi*, or old Persian words, which are no doubt remains of the primeval dialect of mankind. The Thracians peopled a considerable part of the northern coast of Asia Minor; and consequently we meet with many names of cities, mountains, rivers, &c. in those parts, exactly corresponding with many names in Europe, evidently imposed by our Gothic progenitors. Any person tolerably acquainted with the remains of the Gothic tongue, will be able to trace these with little difficulty.

We learn from Herodotus⁵, that Darius in his expedition against the wandering Scythians who lived on the other side of the Ister or Danube, in his progress subdued the Getæ; and in the same passage the historian informs us, that these people held the immortality of the human soul, and that they were the bravest and most just of all the Thracians. After this period, we find them mentioned by almost every Greek writer, even familiarly; for Getæ in the comedies of that nation, is a common name for a slave. The Getæ then occupied all that large tract of country

passim.

(B) Lib. vii. page 295, B.; *ibid.* page 305, G. (Cafaubon). From this passage it appears, that the Greeks were of opinion that the Getæ were Thracians. *Plin. Nat. Hist.* l. iv. cap. 11. mentions a tribe of the Getæ called *Gaudæ*.

Gothic Language. try which extended from the confines of Thrace to the banks of the Danube: were a brave and virtuous people; and spoke the same language with the Thracians, with whom they are often confounded both by Greek and Roman historians.

But the name of *Goths* is by no means so ancient. It was utterly unknown both to the ancient Greeks and Romans. The first time that the name *Goth* is mentioned is in the reign of the Emperor Decius, about the year of Christ 250. About that time they burst out of Getia, and rushing like a torrent into the empire, laid waste every thing with fire and sword. The name of their leader or king was *Cneva*. Decius, endeavouring to expel them Thrace, was vanquished and slain.

After this irruption, we find them frequently in the Latin authors under the name of *Getæ* or *Gothi*; tho' the Greeks generally denominate them *Scythæ*. Torfæus tells us, that *get* and *got* is actually the same word, which anciently, according to him, denoted a "soldier." *Got* in Icelandic signifies a "house or horseman," and *gata* a "wanderer;" and this last was perhaps the import of the term *Getæ*, they being originally an unsettled vagrant people. As nations generally assume to themselves some high auspicious denomination, we may believe the Goths did the same. We may therefore rest satisfied, that the *Getæ* assumed the Icelandic name above mentioned as their national one: or perhaps, notwithstanding their Greek denomination, they called themselves *Gots* or *Goths* from the beginning.

215
Their primary seat. The original seat of the Goths was the country now called *Little Tartary*, into which they had extended themselves from the frontiers of Thrace. This country was called *Little Scythia* by the Greek writers; and it was the station whence these innumerable swarms advanced, which, in conjunction with the Alani and other barbarous tribes, at length overran and subverted the western empire. One part of the Gothic nation was allowed by Constantine to settle in Mœsia. Before the year 420 most of the Gothic nations who had settled within the limits of the Roman empire had been converted to the Christian faith; but, unhappily, the greater part of the apostles by whom they had been profelyted, were Arians, which proved fatal to many of the orthodox Christians; for the Arian Goths persecuted them with unrelenting cruelty.

216
Remains of genuine Gothic. About the year 367, Ulphilas bishop of the Mœsian Goths, translated the New Testament into the Gothic language. The remains of this translation furnish a genuine, and at the same time venerable, monument of the ancient Gothic dialect. No more is now extant of that valuable translation than the four Gospels, and another fragment containing part of the epistle to the Romans. The Gospels have been repeatedly published since the first edition by Junius 1665, down to that of Mr Lye. Other fragments of the Gothic language have also been found, which our curious readers may see in Lye's Notes to his Edition of the Gothic Gospels. The fragment of the Epistle to the Romans was lately discovered in the library at Wolfenbottle, and published by Knitel archdeacon of Wolfenbottle.

The Goths, prior to the age of Ulphilas, were ig-

norant of the use of alphabetical characters. The bishop fabricated an alphabet for them, which is a medley of Greek and Roman letters, but rather inclining to the former.

This alphabet consists of 25 letters (see PLATE IX). Junius has carefully analysed these letters, and pointed out their powers and sounds in his Gothic alphabet, prefixed to his *Glossarium Gothicum*. They were long retained in all the European languages derived from the Gothic source, which will be enumerated in the sequel.

What kind of language the ancient Gothic was, is plain from the fragments above mentioned; but in what respects it agrees with the oriental tongues, or differs from them, is not easy to ascertain with precision. We have observed in our section on the Greek, that a considerable part of that language must have been derived from the Thracian, which, according to Strabo there quoted, was the same with the Getic or Gothic. The Thracian tongue will, we are convinced upon comparison, be found analogous to the Chaldean or Syrian. The German, which is a genuine descendant of the Gothic, is full of Persian words: the old Persian or Pahlavi appears to be a dialect of the Chaldean. The learned Junius, near the beginning of his Gothic alphabet, remarks, that a very considerable part of the language in question is borrowed from the most ancient Greek.

Both the learned Ihre in his *Glossarium Sivo Gothicum*, and Wachter in his excellent German and Latin Dictionary, often remark the coincidence of Gothic and German words with oriental vocables of the like sound and of the same signification. In the old Saxon, which is another ramification of the Gothic tongue, numberless terms of the very same complexion appear. From this deduction we hope it will follow, that the Gothic tongue, in its original unmixed state as it was spoken by the ancient *Getæ*, was a dialect of the primeval language; that language which the sons of Shinar brought with them from the plains of Shinar or from Armenia, or from any other region where the primitive mortals had fixed their residence. To confirm this position, we shall annex a few instances.

The Thracian tribes, in all probability, first took possession of those parts of Asia Minor which stretch towards the east. Thence they crossed the Hellespont, and spread themselves far and wide northward. Strabo supposes that they first settled in the regions to the north of those straits, and thence transported numerous colonies into Asia Minor. The reverse was probably the case. Population, we think, proceeded northward; but be that as it may, is universally agreed, that both sides of the Hellespont were peopled with Thracians.

In Asia Minor we meet with the city Perga, which, throwing away the *a*, is *Perg*. In every tongue descended from the Gothic, the word *Berg* signifies a "rock," and metaphorically a "town or burgh;" because towns were originally built on rocks for the sake of defence. Hence likewise *Pergamos*, the fort or citadel of Troy. *Beira* in Thracian signified a "city;" the Chaldaic and Hebrew word *Beer* imports a "well," and is possibly the original of the Gothic word *beer, ale*. In ancient times, especially in

Gothic
Language.

the East, it was customary to build cities in the neighbourhood of fountains. The ancients called the Plynians *Buzge*, *Byges* or *Bruges*; the Gothic word coinciding is obvious. *Dyndymus*, the name of a city sacred to Cybele, is compounded of two Gothic words *du* and *dim*, both signifying "a height, an eminence;" and hence *a tocon*, an inclosure. The word *triss* seems to be the very Gothic *trosth*, "brave, valiant." The words *fader*, *mader*, *dochter*, *bruder*, are so obviously Persian, that every etymologist has assigned them to that language.

Many futile etymologies have been given of the sacred name *God*, which is in reality the Persian word *Choda*, commonly applied by them to their *Hormazd* or *Oromazds*. The Persian *bad* or *bod* signifies a "city;" the same word in Gothic imports a "house, a mansion, an abode." *Band*, in Persian, a "strait place;" in Gothic, "to bend." *Haim* or *han*, "a house," is generally known to be of Persian original. Much critical skill has been displayed in tracing the etymology of the Scotch and old English word *Tule*, "Christmas." *Tul*, derived from *iul*, was a festival in honour of the sun, which was originally celebrated at the winter solstice. *Wick* or *wich* is a Gothic term still preserved in many names of towns; it signifies "a narrow corner, or small strip of land jutting into the sea, or into a lake or river:" hence Latin *vicus*, and the Greek *vicus*. In Spanish, we have many old Gothic words; among others *hijo* a "son," the same with the Greek *vios*. In some places of Scotland, we call any thing that is little, small, *wee*; originally spelt *wi*, if we mistake not, from the very same word.

These few examples we have thrown together, without any regard to order, persuaded that almost every word of the language, truly Gothic, may with a little pains and judgment be traced to some oriental root or cognate. We may observe in passing, that many Gothic nouns end in *a*, like the Chaldaic and Syriac; that their substantive verb very much resembles that of the Persian, Greek, and Latin: and that their active and auxiliary verb has furnished the common præterperfect tense of Greek verbs in the active voice: that verb is *halan*, but originally *ha*, as the common people pronounce it at this day, especially in the north of Scotland, and among the Swedes, Danes, Norwegians, and Icelanders.

We shall now leave the other inferior arrangements of this ancient language to grammarians and lexicographers, and proceed to inquire what modern tongues are deduced from it as their stock, and which of them makes the nearest approaches to its simplicity and rusticity.

We have already observed that the Goths, formerly Getae, were possessed of a vast extent of country, reaching from the frontiers of Thrace to the banks of the Ister or Danube. We have seen that a colony of them settled in Mœsia under Constantine II. They then spread themselves into Dacia, and from thence into Germany. All these countries were situated in such a manner, that the progress of population was forward, and according to the natural course of emigration. From Germany they extended themselves into Scandinavia, that is, Sweden, Denmark, and Norway. Their whole ancient *Edda*, *Sagas*, "Char-

nicles," show that the Goths arrived in Scandinavia by this route, without, however, fixing the era of that event with any tolerable degree of accuracy. By the Germans, we believe the ancients understood all the nations eastward, westward, and northward, reaching from the Danube on the south up to the extremity of Scandinavia on the Northern Ocean; and from the Rhine and German Ocean on the west, to the river Chronus or Niemen on the east. All those nations spoke one or other of the Gothic dialects, some approaching nearer, and others deviating farther from, the parent language.

The Francic is a dialect of the Teutonic, *Tudesque*, or old German; and the Gospels of Ulphilas bear such a resemblance to the Francic, fragments of which are preserved in the early French historians, that some learned men have pronounced those gospels to be part of an old Francic version; but others of equal respectability have refuted this opinion, both from history and comparison of the dialects. Schilter has given us large monuments of the *Tudesque* or old German from the seventh century, which evidently prove that the Gothic of Ulphilas is the same language. Wachter's learned Glossary of the ancient German likewise confirms this position. Mr Ihre, after hesitating whether the Gospels of Ulphilas bear most resemblance to the German or Scandinavian dialect of the Gothic, declares at last in favour of the former. The Anglo-Saxon is also known to be a venerable dialect of the *Tudesque*; and is so intimately connected with the Gospels, that some valuable works on this subject are wholly built upon the supposition.

The Icelandic is the oldest relic of the Scandinavian. It begins with Arius Frode in the eleventh century, and is a dialect of the German. The remains we have of it are more modern by four centuries than those of the German: they are more polished than the other. The words are shortened, not only because they are more modern than the German, but because the Icelandic was polished by a long succession of poets and historians almost equal to those of Greece and Rome. Hence the Icelandic, being a more polished language than the German, has less affinity with the parent Gothic. The Swedish is more nearly related to the Icelandic than either the Danish or Norwegian. That the Swedish is the daughter of the Gothic, is fully shown by Mr Ihre above mentioned in his *Glossarium Suiæ Gothi. um*. There is, therefore, no manner of doubt as to the identity of the Gothic, preserved in Ulphilas and other ancient remains, with the German and Scandinavian tongue.

The modern German, a language spoken in a far greater extent than any other of modern Europe, resembles the Gothic Gospels more than the present Danish, Norwegian, or Swedish; and has certainly more ancient *flamina*. Its likeness to the Asiatic tongues, in harshness and inflexible thickness of sound, is very apparent.

Busbequius shows, that the clowns of Cisca Tartary, remains of the ancient Goths, speak a language almost German. These clowns were no doubt descendants of the ancient Goths, who remained in their native country after the others had emigrated. It is therefore apparent from the whole of this investigation,

Slavonian Language tion, that the Gothic was introduced into Europe from the East, and is probably a dialect of the language originally spoken by men.

§ 3. *Of the Slavonian Language.*

220 Slavonian language,

THERE is another language which pervades a considerable part of Europe, and this, like the Gothic, seems to have originated in the East. The language we mean is the Slavonic or rather Slavonic, which prevails far and wide in the eastern parts of this division of the globe. It is spoken by the Dalmatians, by the inhabitants of the Danubian provinces, by the Poles, Bohemians, and Russians. The word *slav*, that is, "slave" (whence the French word *esclave*, and our word *slave*), signifies "noble, illustrious;" but because, in the lower ages of the Roman empire, vast multitudes of these people were spread over all Europe in the quality of slaves, that word came to denote the servile tribe by way of distinction, in the same manner as the words *Geta*, *Davus*, and *Syrus*, did among the Greeks at a more early period.

221 Spoken by the Slavi one of the tribes of the Sarmatians,

The Slavi dwelt originally on the banks of the Borysthenes, now the Dnieper or Nieper. They were one of the tribes of the European Sarmatians who in ancient times inhabited an immense tract of country, bounded on the west by the Vistula, now the Weisfel; on the south-east by the Euxine Sea, the Bosphorus Cimmerius, the Palus Mæotis, and the Tanais or Don, which divides Europe from Asia.

In this vast tract of country, which at present comprehends Poland, Russia, and a great part of Tartary, there dwelt in ancient times many considerable tribes. To enumerate these, we believe, would not much edify our readers: we shall only inform them, that among these Sarmatian clans were the Roxolani, now the Russians, and likewise the Slavi, who dwelt near the Borysthenes, as was observed above.

The Slavi gradually advanced towards the Danube; and in the reign of Justinian having passed that river, they made themselves masters of that part of Illyricum which lies between the Drave and the Save, and is to this day from them called *Slavonia*. These barbarians by degrees over-ran Dalmatia, Liburnia, the western parts of Macedonia, Epirus; and on the east they extended their quarters all along to the western bank of the Danube, where that river falls into the Euxine. In all these countries, the Slavonian was deeply impregnated with the Greek, which was a thing of course, since the barbarian invaders settled in those regions, and mingled with the aborigines, who spoke a corrupt dialect of that language.

222 The Poles,

The Poles are the genuine descendants of the ancient Sarmata (c), and consequently speak a dialect of their language, but much adulterated with Latin words, in consequence of the attachment the Poles have long professed to the Roman tongue.

223 Silesians, and

The Silesians and Bohemians have corrupted their dialects in the very same manner. In those countries, then, we are not to search for the genuine remains of the ancient Sarmatian.

The modern Russians, formerly the Rhoxani or Roxolani, are the posterity of the Sarmata, and are a branch of the Slavi: they inhabit a part of the country which that people possessed before they fell into the Roman provinces; they speak the same language, and wear the very same dress; for, on the historical pillar at Constantinople, the Slavonians are dressed like the Russian boors. If then the Slavi are Sarmata, the Russians must of course be the descendants of the same people. They were long a sequestered people, and consequently altogether unconnected with the other nations of Europe. They were strangers to commerce, inhospitable to strangers, tenacious of ancient usages, averse to improvements of every kind, wonderfully proud of their imaginary importance; and, in a word, a race of people just one degree above absolute savagism. A people of this character are, for the most part, enemies to innovations; and if we may believe the Russian historians, no nation was ever more averse to innovations than the one in question. From the ninth century, at which era they embraced Christianity, it does not appear that they moved one step forward towards civilization, till Peter the Great, not a century ago, in consequence of his despotic authority, compelled them to adopt the manners and customs of their more polished neighbours.

Slavonian Language. 224 Russians descended from the Slavi.

We may then conclude, that the Russians made a little change in their language during that period, as they did in their dress, habits, and manner of living. Whatever language they spoke in the ninth century, the same they employed at the beginning of the 18th. They were, indeed, according to *Appian de bel. Michrid.* once conquered by Diophantus, one of Mithridates's generals; but that conquest was for a moment only: they were likewise invaded, and their country over-run, by the great Timor or Tamerlane; but this invasion was like a torrent from the mountains, which spreads devastation far and wide while it rages, but makes little alteration on the face of the country.

We find, likewise, that upon some occasions they made incursions upon the frontiers of the Roman empire; but we hear of no permanent settlements formed by them in these quarters. Upon the whole, we take the Russians to have been, with respect to their language, in the very same predicament with the Highlanders and Islanders of Scotland, who, according to the general opinion, have preserved the Celtic dialect pure and entire, in consequence of their having never mingled with foreigners.

From this deduction we may infer two things; first, that the Russian language is the genuine Slavonian; and, secondly, that the latter is the same, or nearly the same, with the ancient Sarmatian.

225 The Russian language genuine Slavonic.

In the Russian, there are found a great number of words resembling the old simple roots of the Greek both in sound and signification; its grammatical genius is nearly the same; and we are informed by the very best authority, that there is in this language a translation of Epictetus, in which there are whole pages, in both the original and translation, without one single

(c) This appears by their character, their laws, their manners, their form of government, their military equipage, their impetuosity, their aristocratic splendour.

Slavonian
Language.

single transposition. Monf. Leveque, who has published a translation of a history of Russia, is so entirely convinced of the strict analogy between the ancient Greek and the modern Russe, that he is positive that the former is derived from the latter. Monf. Freret, a very learned French academician, is clearly of the same opinion. We are, however, persuaded that this opinion is ill founded. We rather imagine, that those coincidences arise from the relics of the primitive language of mankind; vestiges of which, we believe, are to be found almost in every tongue now existing.

226
Resem-
blance be-
tween Rus-
sian and
oriental
words.

It is, however, we allow, uncommonly difficult to render a reason for the syntactical analogy of the two languages, without admitting the truth of the one or the other hypothesis. We have examined with some care a good number of Russian vocables, and compared them with Greek ones of the same signification. We have not, however, found such a resemblance as we think necessary to support the position advanced above. We have indeed found a very strong resemblance between the former and many oriental words, especially Hebrew, Chaldean, and old Persian, of which we could produce several instances, did the nature of our present inquiry admit such a deviation. Every body knows that the Sarmatæ were divided into two great nations, the Asiatic and European; the former extended very far eastward, behind the mountain Caucasus, the northern shore of the Euxine Sea, and so forth. These, we may believe, derived their language from the original tongue long before the Greek language existed. This, in comparison of the Hebrew, Phœnician, Egyptian, Arabian, Chaldean, &c. was but of yesterday. The Greek, most learned men are now convinced, was a late composition of many different dialects, incorporated with the jargon of the aboriginal Ionim or Greeks. The Sarmatian, on the contrary, was the tongue of a great and populous nation, civilized, in all appearance, long before the Greeks began to emerge from a state of savagism. We are, therefore, by no means disposed to allow, either that the Greek is derived from the Russian, or the Russian from the Greek. We believe there is just the same reason for this conclusion that the Abbé Pezron and Monf. Gebelin pretend to have discovered, in order to support their position that the Greek is derived from the Celtic. Certain it is, that the resemblance among the oriental languages, of which we take the Sarmatian to have been one, is so palpable, that any person of a moderate capacity who is perfectly master of one, will find little difficulty in acquiring any other. If, therefore, the coincidence between the Greek and Russian should actually exist, we think this circumstance will not authenticate the supposition, that either of the two is derived from the other.

In the course of this argument, our readers will be pleased to observe, that we all along suppose, that the Slavonian, of which we think the Russian is the most genuine remain, is the same with the old Sarmatian. We shall now take the liberty to hazard a conjecture with respect to the syntactical coincidence of that language with the Greek; for we acknowledge that we are not so profoundly versed in the Russian dialect of

the Slavonian as to pretend to pronounce a definitive Slavonian
Language.

As the Russians were a generation of savages, there is no probability that they were acquainted with the use of letters and alphabetical writing till they acquired that art by intercourse with their neighbours. It is certain, beyond all contradiction, that few nations had made less proficiency in the fine arts than that under consideration: and we think there is little appearance of their having learned this art prior to their conversion to Christianity. Certain it is, that the Slavi, who settled in Dalmatia, Illyria, and Liburnia, had no alphabetical characters till they were furnished with them by St Jerome. The Servian character, which very nearly resembles the Greek, was invented by St Cyril; on which account the language written in that character is denominated *Chirilizza*. These Slavonic tribes knew nothing of alphabetic writing prior to the era of their conversion. The Mœsin Goths were in the same condition till their Bishop Ulphilas fabricated them a set of letters.

227
Origin of
the syn-
taxical
coincidence
between
this and
the Greek
language.

If the Slavi and Goths, who resided in the neighbourhood of the Greeks and Romans, had not learned alphabetical writings prior to the era of their conversion to Christianity, it must hold *à fortiori*, that the Russians, who lived at a very great distance from those nations, knew nothing of this useful art antecedent to the period of their embracing the christian faith.

The Russians pretend that they were converted by St Andrew; but this is known to be a fable. Christianity was first introduced among them in the reign of the grand Duke Wolodimar, who marrying the daughter of the Grecian emperor Basilus, became her convert about the year 989. About this period, we imagine, they were taught the knowledge of letters by the Grecian missionaries, who were employed in teaching them the elements of the Christian doctrines. Their alphabet consists of 31 letters, with a few obsolete additional ones; and these characters resemble those of the Greeks so exactly, that there can be no doubt of their being copied from them. It is true, the shape of some has been somewhat altered, and a few barbarian ones have been intermingled. The Russian liturgy, every body knows, was copied from that of the Greeks; and the best specimen of the old Russian is the church offices for Easter, in the very words of Chryostom, who is called by his name *Zlato usii*, "golden-mouthed." The power of the clergy in Russia was excessive; and no doubt their influence was proportioned to their power. The first race of clergy in that country were undoubtedly Greeks. We know how active and industrious those people were in propagating their language as well as their religion. The offices of religion might be at first written and pronounced in the Greek tongue, but it would soon be found expedient to have them translated into Russian. The persons employed in this work must have been Greeks, who understood both languages.

As it is confessedly impossible that a people so dull and uninventive as the Russians originally were, could ever have fabricated a language so artificially constructed as their present dialect; and as it is obvious, that, till Christianity was introduced among them by the Greeks, they could have no correspondence with that
people—

Scalvonian Language. people—it must appear surprising by what means their language came to be fashioned so exactly according to the Greek model. We have observed above, that the Russian letters must have been invented and introduced into that country by the Greek missionaries. We think it probable, that those apostles, at the same time that they taught them a new religion, likewise introduced a change into the idiom of their language. The influence of those ghostly teachers over a nation of savages must have been almost boundless; the force of their precepts and example almost uncontrollable. If the savage converts accepted a new religion from the hands of those Grecian apostles, they might with equal submission adopt improvements in their language. Such of the natives as were admitted to the sacerdotal function must have learned the Greek language, in order to qualify them for performing the offices of their religion. A predilection for that language would be the immediate consequence. Hence the natives, who had been admitted into holy orders, would co-operate with their Grecian masters in improving the dialect of the country; which, prior to the period above mentioned, must have greatly deviated from the original standard of the Sarmatian tongue.

Upon this occasion, we imagine the Greek apostles, in conjunction with their Russian disciples, reduced the language of the country to a resemblance with the Greek idiom. They retained the radical vocables as they found them; but by a variety of flexions, conjugations, derivations, compositions, and other modifications, transformed them into the Grecian air and apparel. They must have begun with the offices of the church; and among a nation of savages newly converted, the language of the new religion would quickly obtain a very extensive circulation. When the Grecian garniture was introduced into the church, the laity would in process of time assume a similar dress. The fabric of the Grecian declensions, conjugations, &c. might be grafted upon Russian stocks without affecting the radical parts of the language. If the dialect in question, like most others of a very ancient date, laboured under a penury of vocables, this manœuvre would contribute exceedingly to supply that defect. By this expedient the Greek language itself had been enlarged from about 300 radical terms to the prodigious number of words of which it now consists.

The Latin tongue we have seen above in its original constitution differed widely from the Greek; and notwithstanding this incongruity, the improvers of the former have pressed it into a very strict agreement with the latter. This, we think, was still a more difficult task; as, in our opinion, the genius of the Latin differs in a much greater degree than that of the Russian does from the Greek. We know, that the genius of the Gothic tongue and those of all its descendants are much more in unison with the Greek than with that of the Latin. The Spanish, Italian, and French, have worked many of their Gothic, Teutonic, and Celtic verbs, into a kind of conjugations, imitating or rather aping those of the Latin. The Persians have formed most elegant and energetic declensions and conjugations, upon inflexible roots, borrowed from the Pahlavi and Deri, and even from Tartar originals.

Upon the grounds above-mentioned we have taken

the liberty to hazard the following conjectures, which we cheerfully submit to the cognizance of our more enlightened readers.

1. That the Sarmatian was a dialect of the original language of mankind.
2. That the Scalvonian was a dialect of the Sarmatian.
3. That the Russe is the most genuine unsophisticated relic of the Scalvonian and Sarmatian.
4. That the Russians had no alphabetic characters prior to the era of the introduction of Christianity, that is, towards the end of the tenth century.
5. That they were converted by Grecian missionaries.
6. That those missionaries copied their present letters from those of Greece; and in conjunction with the more enlightened natives, reduced the original unimproved Russe to its present resemblance to the Greek standard.

The Russian language, like most others, contains eight parts of speech, noun, pronoun, &c. Its nouns have three genders, masculine, feminine, and neuter; it has also a common gender for nouns, intimating both sexes. It has only two numbers, singular and plural. Its cases are seven, nominative, genitive, dative, accusative, vocative, instrumental, and prepositive. These cases are not formed by varying the termination, as in Greek and Latin: but generally by placing a vowel after the word, as, we imagine, was the original practice of the Greeks (See *Greek Section*). Thus in Russe, *рука*, "hand;" nominative, *рука* "the hand;" genitive, *руки* "of the hand," &c. See *Les Elem. de la Langue Russe par Charpentier*. Nouns substantive are reduced to four declensions, and adjectives make a fifth. These agree with their substantives in case, gender, and number. They have three degrees of comparison, as is common in other languages; the positive, comparative and superlative. The comparative is formed from the feminine of the nominative singular of the positive, by changing *a* into *ie*, that is *aié* in English; the superlative is made by prefixing *пре*, before the positive. These rules are general; for the exceptions, recourse must be had to the Russian grammar above-mentioned.

The numeral adjectives in Russe have three genders like the rest, and are declined accordingly. Their pronouns have nothing peculiar, and are divided and arranged in the same manner as in other languages. Verbs in the Russian language are comprehended under two conjugations. The moods are only three; the indicative, the imperative, and the infinitive; the subjunctive is formed by placing a participle before the indicative. Its tenses are eight in number; the present, the imperfect, the preterite simple, the preterite compound, the pluperfect, the future indeterminate, the future simple, the future compound. The verbs have their numbers and persons as in other languages. To enter into a detail of their manner of conjugating their verbs would neither be consistent with our plan, nor, we are persuaded, of much consequence to our readers. Their other parts of speech differ nothing from those of other languages. Their syntax nearly resembles that of the Greek and Latin. All these articles must be learned from a grammar of the language. Whether there is any grammar of the Russian language com-
posed

Slavonian
Language.

fed in English we know not. That of Monf. Charpentier in French, printed at Peterburgh in 1768, is the only one we have feen, and which appears to us a very excellent one. We could wifh to be able to gratify our readers with a more authentic account of the origin of the Slavonian language; but this we find impoffible, in confequence of the want of memoirs relating to the ftate of the ancient Sarmata. Towards the era of the fubverfion of the weftern empire, the nations who inhabited the countries in queftion were fo blended and confounded with each other, and with Huns and other Scythian or Tartar emigrants, that we believe the moft acute antiquarian would find it impoffible to investigate their refpective tongues, or even their original refidence or extraction. We have flected the Ruffe as the moft genuine branch of the old Slavonian, and to this predilection we were determined by the reafons above mentioned. We are forry that we are not fo well acquainted with the idiom of the Ruffian language as to be able to compare it with thofe of the east: but upon fuch a comparison, we are perfuaded that the radical materials of which it is compofed would be found to have originated in the oriental regions. The word *Tfar*, for example, is probably the Phœnician and Chaldean *Sar* or *Zar*, "a prince, a grandee." Diodorus Siculus calls the queen of the Maffagetæ, who, according to Ctefias, cut off Cyrus's head, *Zarina*; which was not many years ago the general title of the empress of all the Ruffias. Herodotus calls the fame princefs *Tomyris*, which is the very name of the famous Timor or Tamur, the conqueror of Afia. The former feems to have been the title, and the latter the proper name, of the queen of the Maffagetæ. In the old Perfian or Pahlavi, the word *Gard* fignifies "a city;" in Ruffian *Gorod* or *Grad* intimates the very fame idea: hence *Constantinople* in old Ruffe is called *Tfargrad* or *Tfargorad*. Thefe are adduced as a fpecimen only; an able etymologift might, we believe, difcover a great number.

The Slavonian language is fpoken in Epirus, the weftern part of Macedonia, in Bofnia, Servia, Bulgaria, in part of Thrace, in Dalmatia, Croatia, in Poland, Bohemia, Ruffia, and Mingrelia in Afia, whence it is frequently ufed in the feraglio at Constantinople. Many of the great men of Turkey underftand it, and frequently ufe it; and moft of the janizaries having been ftationed in garrifons in the Turkish frontiers in Europe, ufe it as their vulgar tongue. The Hungarians, however, and the natives of Wallachia, fpeak a different language: and this language bears evident fignatures of the Tartarian dialect, which was the tongue of the original Huns. Upon the whole, the Slavonian is by much the moft extenfive language in Europe, and extends far into Afia.

SECT. X. Modern Languages.

IF we call all the different dialects of the various nations that now inhabit the known earth, languages, the number is truly great; and vain would be his ambition who fhould attempt to learn them, though but imperfectly. We will begin with naming the principal of them: There are four, which may be called

original or mother languages, and which feem to have given birth to all that are now fpoken in Europe. Thefe are the *Latin*, *Celtic*, *Gothic*, and *Slavonian*. It will not, however, be imagined, from the term *original* given to thefe languages, that we believe them to have come down to us, without any alteration, from the confufion of tongues at the building of the tower of Babel. We have repeatedly declared our opinion, that there is but one truly original language, from which all others are derivatives variously modified. The four languages juft mentioned are original only as being the immediate parents of thofe which are now fpoken in Europe.

I. From the *Latin* came,

1. The Portuguefe.
2. Spanifh.
3. French.
4. Italian.

From the *Celtic*,

5. The Eufe, or Gaelic of the Highlands of Scotland.
6. The Welch.
7. The Irifh.
8. Baffe-Bretagne.

From the *Gothic*,

9. The German.
10. The Low Saxon or Low German.
11. The Dutch.
12. The Englifh; in which almoft all the noun-fubftantives are German, and many of the verbs French, Latin, &c. and which is enriched with the fpoils of all other languages.
13. The Danifh.
14. The Norwegian.
15. Swedifh.
16. Icelandic.

From the *Slavonian*,

17. The Polonefe.
18. The Lithuanian.
19. Bohemian.
20. Tranfylvanian.
21. Moravian.
22. The modern Vandalian, as it is ftill fpoken in Lufatia, Pruffian Vandalia, &c.
23. The Croatian.
24. The Ruffian or Mufcovite; which, as we have feen, is the pureft dialect of this language.
25. The language of the Calmucs and Cofacks.
26. Thirty-two different dialects of nations who inhabit the north-eaftern parts of Europe and Afia, and who are defcended from the Tartars and Hunno-Scythians. There are polyglott tables which contain not only the alphabets, but alfo the principal diftinct characters of all thefe languages.

II. The languages at prefent generally fpoken in Afia are,

27. The Turkish and Tartarian, with their different dialects.
28. The Perfian.
29. The Georgian or Iberian.
30. The Albanian or Circaffian,
31. The Armenian.

These languages are fpoken by the Greek Chriftians in Afia, under the patriarch of Conftantinople.

235
Afatic
languages

- Modern Languages. 32. The modern Indian.
 33. The Formosan.
 34. The Indostanic.
 35. The Malabarian.
 36. The Warugian.
 37. The Talmulic or Dalmulic. } The Danish missionaries who go to Tranquebar, print books at Hall in these languages.
 38. The modern Arabic.
 39. The Tangutian.
 40. The Mungalic.
 41. The language of the Nigarian or Akar Nigarian.
 42. The Grufinic or Grufinian.
 43. The Chinese.
 44. The Japanese.

We have enumerated here those Asiatic languages only of which we have some knowledge in Europe, and even alphabets, grammars, or other books that can give us information concerning them. There are doubtless other tongues and dialects in those vast regions and adjacent islands; but of these we are not able to give any account.

- 234 African language. III. The principal languages of Africa are,
 45. The modern Egyptian.
 46. The Fetuitic, or the language of the kingdom of Fetu.
 47. The Moroccan; and,
 48. The jargons of those savage nations who inhabit the desert and burning regions. The people on the coast of Barbary speak a corrupt dialect of the Arabic. To these may be added the Chilhic language, otherwise called *Tamazecht*; the Negritian and that of Guinea; the Abyssinian; and the language of the Hottentots.

- 235 American languages. IV. The languages of the American nations are but little known in Europe. Every one of these, though distant but a few days journey from each other, have their particular language or rather jargon. The languages of the Mexicans and Peruvians seem to be the most regular and polished. There is also one called *Poconchi* or *Pocomana*, that is used in the bay of Honduras and toward Guntimal, the words and rules of which are most known to us. The languages of North America are in general the Algonhic, Apalachian, Mohogic, Savanahamic, Virginic, and Mexican; and in South America, the Peruvian, Caribic, the language of Chili, the Cairic, the Tucumanian, and the languages used in Paraguay, Brasil, and Guiana.

236 General reflections on modern languages. V. We have already said, that it would be a vain and senseless undertaking for a man of letters to attempt the study of all these languages, and to make his head an universal dictionary; but it would be still more absurd in us to attempt the analysis of them in this place: some general reflections the more must here suffice. Among the modern languages of Europe, the French seems to merit great attention; as it is elegant and pleasing in itself; as it is become so general, that with it we may travel from one end of Europe to the other without scarce having any occasion for an interpreter; and as in it are to be found excellent works of every kind, both in verse and prose, useful and agreeable. There are, besides, grammars and dictionaries of this language, which give us every information concerning it, and very able masters

who teach it; especially such a one, from whom the French of France where it is spoken commonly, has not the same advantages, the French language has not the same convenience, that it is pronounced scarce any where purely but at Paris and on the banks of the Seine. The language of the court, of the great world, and of men of letters, is moreover very different from that of the common people; and the French tongue, in general, is subject to great alteration and novelty. What pity it is, that the style of the great Corneille, and that of Moliere, should already begin to be obsolete, and that it will be but a little time before the inimitable *chefs d'œuvres* of those men of sublime genius will be no longer seen on the stage! The most modern style of the French, moreover, does not seem to be the best. We are inclined to think, that too much conciseness, the epigrammatic point, the paradox, the sententious expression, &c. diminish its force; and that, by becoming more polished and refined, it loses much of its energy.

VI. The German and Italian languages merit likewise a particular application; as does the English, perhaps above all, for its many and great excellencies (See LANGUAGE). Authors of great ability daily labour in improving them; and what language would not become excellent, were men of exalted talents to make constant use of it in their works? If we had in Iroquois books like those which we have in English, Italian, French, and German, should we not be tempted to learn that language? How glad should we be to understand the Spanish tongue, though it were only to read the Araucana of Don Alonzo D'Ercilia, Don Quixote, some dramatic pieces, and a small number of other Spanish works, in the original; or the poem of Camoens in Portuguese.

VII. The other languages of Europe have each their beauties and excellencies. But the greatest difficulty in all living languages constantly consists in the pronunciation, which it is scarce possible for any one to attain unless he be born or educated in the country where it is spoken: and this is the only article for which a master is necessary, as it cannot be learned but by teaching or by conversation: all the rest may be acquired by a good grammar and other books. In all languages whatever, the poetic style is more difficult than the prosaic: in every language we should endeavour to enrich our memories with great store of words (*copia verborum*), and to have them ready to produce on all occasions: in all languages it is difficult to extend our knowledge so far as to be able to form a critical judgment of them. All living languages are pronounced rapidly, and without dwelling on the long syllables (which the grammarians call *trivium*): almost all of them have articles which distinguish the genders.

VIII. Those languages that are derived from the Latin have this further advantage, that they adopt without restraint, and without offending the ear, Latin and Greek words and expressions, and which by the aid of a new termination appear to be natives of the language. This privilege is forbidden the Germans, who in their best translations dare not use any foreign word, unless it be some technical term in case of great necessity.

Philomathes
||
Philopœmen.

PHILOMATHES, a lover of learning or science. **PHILOMELA**, in fabulous history, was a daughter of Pandion king of Athens, and sister to Procne, who had married Tereus king of Thrace. Procne separated from Philomela, to whom she was much attached, spent her time in great melancholy till she prevailed upon her husband to go to Athens and bring her sister to Thrace. Tereus obeyed, but he had no sooner obtained Pandion's permission to conduct Philomela to Thrace, than he fell in love with her, and resolved to gratify his passion. He dismissed the guards whom the suspicions of Pandion had appointed to watch him; offered violence to Philomela; and afterwards cut out her tongue, that she might not discover his barbarity, and the indignities she had suffered. He confined her in a lonely castle; and having taken every precaution to prevent a discovery, he returned to Thrace, and told Procne that Philomela had died by the way, and that he had paid the last offices to her remains. At this sad intelligence Procne put on mourning for the loss of Philomela; but a year had scarcely elapsed before she was secretly informed that her sister was not dead. Philomela, in her captivity, described on a piece of tapestry her misfortunes and the brutality of Tereus, and privately conveyed it to Procne. She was going to celebrate the orgies of Bacchus when she received it, but she disguised her resentment; and as during those festivals she was permitted to rove about the country, she hastened to deliver her sister Philomela from her confinement, and concerted with her on the best measures of punishing the cruelty of Tereus. She murdered her son Itylus, then in the sixth year of his age, and served him up as food before her husband during the festival. Tereus, in the midst of his repast, called for Itylus; but Procne immediately informed him that he was then feasting on his flesh, when Philomela, by throwing on the table the head of Itylus, convinced the monarch of the cruelty of the scene. He drew his sword to punish Procne and Philomela; but as he was going to slay them to the heart, he was changed into a hoopoe, Philomela into a nightingale, Procne into a swallow, and Itylus into a pheasant. This tragedy happened at Daulis in Phœcis; but Pausanias and Strabo, who mention the whole of the story, are silent about the transformation; and the former observes, that Tereus, after this bloody repast, fled to Megara, where he laid violent hands on himself. The inhabitants of the place raised a monument to his memory, where they offered yearly sacrifices, and placed small pebbles instead of barley. It was on this monument that the birds called hoopoes were first seen; hence the fable of his metamorphosis. Procne and Philomela died thro' excess of grief and melancholy; and as the nightingale's and the swallow's voice is peculiarly plaintive and mournful, the poets have embellished the fable by supposing that the two unfortunate sisters were changed it to birds.

PHILONIUM, in pharmacy, a kind of somniferous anodyne opiate, taking its name from Philo the inventor.

PHILOPÆMEN, a celebrated general of the Achaean league, was born in Megalopolis, a city of Arcadia in Peloponnesus; and from his very infancy discovered a strong inclination to the profession of

arms. He was nobly educated by Cassander of Mantinea; a man of great probity, and uncommon abilities. He was no sooner able to bear arms than he entered among the troops which the city of Megalopolis sent to make incursions into Laconia, and in these incursions never failed to give some remarkable instance of his prudence and valour. When there were no troops in the field, he used to employ his leisure time in hunting and such other manly exercises. When Cleomenes king of Sparta attacked Megalopolis, Philopœmen displayed much courage and greatness of soul. He signalized himself no less some time after, in the battle of Sellasia, where Antigonus gained a complete victory over Cleomenes. Antigonus, who had been an eye-witness of his prudent and intrepid behaviour, made very advantageous offers to gain him over to his interest; but he rejected them, having an utter aversion to a court life, which he compared to that of a slave, saying, that a courtier was but a slave of a better condition. As he could not live idle and inactive, he went to the isle of Crete, which was then engaged in war, and served there as a volunteer till he acquired a complete knowledge of the military art; for the inhabitants of that island were in those days accounted excellent warriors, being scarce ever at peace among themselves. Philopœmen, having served some years among the troops of that island, returned home, and was upon his arrival appointed general of the horse; in which command he behaved so well, that the Achaean horse, heretofore of no reputation, became in a short time famous all over Greece. He was soon after appointed general of the Achaean forces, when he applied himself to the re-establishing of military discipline among the troops of the republic, which he found in a very low condition, and universally despised by their neighbours. Aratus, indeed, was the first that raised the Achaean state to that pitch of power and glory to which it arrived; but the success of his enterprises was not so much owing to his courage and intrepidity as to his prudence and politics. As he depended on the friendship of foreign princes, and their powerful succours, he neglected the military discipline at home; but the instant Philopœmen was created prator, or commander in chief, he roused the courage of his countrymen, in order to put them into a condition to defend themselves without the assistance of foreign allies. With this view he made great improvements in the Achaean discipline; changing the manner of their exercise and their arms, which were both very defective. He had thus, for the space of eight months, exercised his troops every day, making them perform all the motions and evolutions, and accustoming them to manage with dexterity their arms, when news was brought him that Machanidas was advancing, at the head of a numerous army to invade Achaia. He was glad of this opportunity to try how the troops had profited by his discipline; and accordingly, taking the field, met the enemy in the territories of Mantinea, where a battle was fought. Philopœmen, having killed Machanidas with his own hand, struck off his head, and carried it from rank to rank, to encourage his victorious Achæans, who continued the pursuit with great slaughter, and incredible ardour to the city of Tegea, which they entered together with the fugitives. The Lacedæmonians lost

Philopœmen.

Philopæ
men.

on this occasion above 8000 men, of which 4000 were killed on the spot, and as many taken prisoners. The loss of the Achaëans was very inconsiderable, and those that fell were mostly mercenaries. This happened about the year before Christ 204.

But what most of all raised the fame and reputation of Philopœmen was his joining the powerful city of Lacedæmon to the Achæan commonwealth; by which means the Achæans came to eclipse all the other states of Greece. This memorable event happened in the year 191. In this transaction we cannot help taking notice of one circumstance, which in our opinion, reflects greater lustre on Philopœmen than all his warlike exploits. The Lacedæmonians, overjoyed to see themselves delivered from the oppressions they had long groined under, ordered the palace and furniture of Nabis to be sold; and the sum accruing from thence, to the amount of 120 talents, to be presented to Philopœmen, as a token of their gratitude. Deputies therefore were to be appointed, who should carry the money, and desire Philopœmen, in the name of the senate, to accept of the present. On this occasion it was that the virtue of the generous Achæan appeared in its greatest lustre; for so great was the opinion which the Spartans had of his probity and disinterestedness, that no one could be found who would take upon him to offer the present: struck with veneration, and fear of displeasing him, they all begged to be excused. At last they obliged, by a public decree, one Timolaus, who had formerly been his guest, to go to Megalopolis, where Philopœmen lived, and offer him this testimony of their regard. Timolaus, with great reluctance, set out for Megalopolis, where he was kindly received and entertained by Philopœmen. Here he had an opportunity of observing the strictness of his whole conduct, the greatness of his mind, the frugality of his life, and the regularity of his manners; which struck him with such awe, that he did not dare once to mention the present he was come to offer; inasmuch that, giving some other pretence to his journey, he returned home with the money. The Lacedæmonians sent him again; but he could no more prevail upon himself now than the first time to mention the true cause of his journey. At last, going a third time, he ventured, with the utmost reluctance, to acquaint Philopœmen with the offer he had to make in the name of the Lacedæmonians. Philopœmen heard him with great calmness; but the instant he had done speaking, he set out with him for Sparta, where after having acknowledged his obligation to the Spartans, he advised them to lay out their money in reforming or purchasing those miscreants who divided the citizens, and set them at variance by means of their seditious discourses; to the end that being paid for their silence, they might not occasion so many distractions in the government: "for it is much more advisable (said he) to stop an enemy's mouth than a friend's: as for me, I shall always be your friend, and you shall reap the benefit of my friendship without expence." Such was the disinterestedness of this noble Achæan!

About two years after this the city of Messene withdrew itself from the Achæan league. Philopœmen attacked them; but was wounded, taken prisoner, and poisoned by the magistrates. Thus died one of

the greatest heroes that Greece or any other country ever produced. He was no way inferior in valour, military knowledge, and virtue, to any of the boasted heroes of Rome. Had Achæa been nearer to an equality with Rome, he would have prevented this country from the yoke which the Roman republic forced it to bear. Both the Greek and Roman writers put him upon the level with Hannibal and Scipio, who were his contemporaries, and happened to die the same year. They allow him to have been not only one of the greatest commanders, but also one of the greatest statesmen of his age. To his valour and prudence Achæa owed her glory, which upon his death began to decline, there being none after him in that republic able to oppose her enemies with the like steadiness and prudence; whence Philopœmen was called the last of the Greeks, as Brutus was afterwards styled the last of the Romans.

PHILOSOPHER, a person versed in philosophy; or one who makes profession of, or applies himself to, the study of nature and morality.

PHILOSOPHER'S STONE, the greatest object of alchemy, is a long sought for preparation, which, when found, is to convert all the true mercurial part of metal into pure gold, better than any that is dug out of mines or perfected by the refiner's art.

Some Greek writers in the fourth and fifth centuries speak of this art as being then known; and towards the end of the 13th century, when the learning of the East had been brought hither by the Arabians, the same pretensions began to spread through Europe. It is supposed that this art called *alchemy*, was of Egyptian origin; and that, when the ancient Greek philosophers travelled into Egypt, they brought back some of the allegoric language of this Egyptian art, ill understood, which afterwards passed into their mythology. Alchemy was the earliest branch of chemistry, considered as a philosophical science; in the other parts of chemical knowledge, facts preceded reasoning or speculation; but alchemy was originally speculative. See TRANSMUTATION.

The alchemists supposed the general principles of metals to be chiefly two substances, which they called mercury and sulphur; they apprehended also, that the pure mercurial, sulphureous, or other principles of which they imagined gold to be composed, were contained separately in other bodies; and these principles, therefore, they endeavoured to collect, and to concoct and incorporate by long digestions; and by thus conjoining the principles of gold, if they could be so procured and conjoined, it might be expected that gold would be produced. But the alchemists pretend to a product of a higher order, called *the elixir, the medicine for metals, the tincture, the philosopher's stone*; which, by being projected on a large quantity of any of the inferior metals in fusion, should change them into fine gold; which being laid on a plate of silver, copper, or iron, and moderately heated, should sink into the metal, and change into gold all the parts to which it was applied; which on being properly heated with pure gold, should change the gold into a substance of the same nature and virtue with itself, so as thus to be susceptible of perpetual multiplication; and which, by continued cotion, should have its power more and

Ph. of
phar.
Philos-
pher's
stone.

Philoso-
pher's
stone.

more exalted, so as to be able to transmute greater and greater quantities of the inferior metals, according to its different degrees of perfection.

Alchemists have attempted to arrive at the making of gold by three methods: the first by separation; for every metal yet known, it is affirmed, contains some quantity of gold; only, in most, the quantity is so little as not to defray the expence of getting it out.

The second is by maturation; for the alchemists think mercury is the basis and matter of all metals; that quicksilver purged from all heterogeneous bodies would be much heavier, denser, and simpler, than the native quicksilver; and that by subtilizing, purifying, and digesting it with much labour, and long operations, it is possible to convert it into pure gold.

This method is only for mercury. With respect to the other metals, it is ineffectual, 1. Because their matter is not pure mercury, but has other heterogeneous bodies adhering to it; and, 2. Because the digestion, whereby mercury is turned into gold, would not succeed in other metals, because they had not been long enough in the mines.

Weight is the inimitable character of gold, &c. Now mercury, they say, has always some impurities in it, and these are lighter than mercury. Could they be purged away, which they think is not impossible, mercury would be as heavy as gold; and what is as heavy as gold is gold, or at least might very easily be made gold.

The third method is by transmutation, or by turning all metals readily into pure gold, by melting them in the fire, and casting a little quantity of a certain preparation into the fused matter; upon which the feces retire, are volatilized and burnt, and carried off, and the rest of the mass is turned into pure gold. That which works this change in the metals is called the *philosopher's stone*. See TRANSMUTATION.

Whether this third method be possible or not, it is difficult to say. We have so many testimonies of it from persons who on all other occasions speak truth, that it is hard to say they are guilty of direct falsehood, even when they say that they have been masters of the secret. We are told, that it is only doing that by art which nature does in many years and ages. For as lead and gold differ but little in weight, therefore there is not much in lead beside mercury and gold. Now, if we had any body which would to agitate all the parts of lead as to burn all that is not mercury therein, and had also some sulphur to fix the mercury, would not the mass remaining be converted into gold? There is nothing in nature so heavy as lead except gold, mercury, and platina, which was not known to these reasoners; it is evident, therefore, there is something in lead that comes very near to gold. But in lead there is likewise some heterogeneous matter different both from mercury and gold. If therefore 19 ounces of lead be dissolved by the fire, and 8 ounces be destroyed by these means, it is argued that we shall have the rest gold; the ratio of lead to gold being as 11 to 19. If then the philosopher's stone can purify the mercurial matter in lead, so as that nothing shall remain but the pure mercurial body, and you can fix and coagulate this by means of sulphur, out of 19 ounces of lead you will have 11 of gold: or, if you reduce the lead from 18 to 14, you will then have

converted it into mercury; and if you farther purify this mercury to the proper standard, you will have gold; provided you have but a sulphur with which to fix and coagulate it. Such is the foundation of the opinion of the philosopher's stone; which the alchemists contend to be a most subtle, fixed, concentrated fire, which as soon as it meets with any metal, does, by a magnetic virtue, immediately unite itself to the mercurial body of the metal, volatilize and cleanse off all that is impure therein, and leave nothing but a mass of pure gold. Many frauds and artifices have unquestionably been practised in this operation, and there might be political reasons why princes and others should encourage those who pretended to a power of furnishing this inexhaustible source of wealth; but it would be wrong to censure as impostors all those who have declared themselves convinced, from their own experiments, of the transmutability of base metals into gold. There are strong reasons, however, to believe that the authors have been deceived themselves by fallacious appearances. Mr Boyle gives an account of a process by which he imagines part of the substance of gold to have been transmutated into silver. He also relates a very extraordinary experiment, under the title of the degradation of gold by an anti-elixir, which was published in his own life-time, and since re-printed in 1739. Hence many have been led to conclude in favour of the alchemical doctrine of the transmutability of metals. See an account of this experiment, with remarks upon it by Dr Lewis, in his *Commerce of Arts*, sect. 12. p. 297, &c.

"The opinion (says Holt) that one metallic or other foreign substance might be changed into another, was, it seems, at this time (reign of Henry VI. of England) propagated by certain chemists, whose observations on the surprising effects and alterations produced in certain substances by the force of heat carried their imaginations beyond what sound judgment might warrant. The first instance of which on record is in vol. xi. p. 68. of the *Fædera*; wherein Henry VI. grants a licence to John Cobbe, freely to work in metals; he having, by philosophical art, found out a method of transferring imperfect metals into perfect gold and silver.

"This pretended secret, known afterwards by the name of the *philosopher's stone* or *powder*, was encouraged by four licences, granted to different projectors during this reign, and at sundry times after, during this century particularly, and in succeeding times, all over Europe. The pleremy has not entirely ceased even to this day, although it meets with neither public encouragement nor countenance from men of sober reason; the projectors having yet found nothing from their airy schemes in this mode of search but certain ruin to their property."

The same author, when speaking of the commerce of the kingdom, and the wonderful increase and riches of commercial cities, speaks thus: "This is the true philosopher's stone, so much sought after in former ages, the discovery of which has been reserved to genius, when studying to improve the mechanic arts. Hence a pound of raw materials is converted into stuffs of fifty times its original value. And the metals too are not, indeed, transmutated into gold—they are more:

Definitions
of philoso-
phy.

IS a word derived from the Greek, and literally signifies the love of wisdom (A). In its usual acceptance, however, it denotes a science, or collection of sciences, of which the universe is the object; and of the term thus employed many definitions have been given, differing from one another according to the different views of their several authors. By Pythagoras, philosophy is defined επιστημη των εναντων, "the knowledge of things existing;" by Cicero, after Plato, scientia rerum divinarum et humanarum cum civis; and by the illustrious Bacon, interpretatio nature. Whether any of these definitions be sufficiently precise, and at the same time sufficiently comprehensive, may be questioned; but if philosophy in its utmost extent be capable of being adequately defined, it is not here that the definition should be given. "Explanation (says an acute writer *), is the first office of a teacher; definition if it be good, is the last of the inquirer after truth; but explanation is one thing, and definition quite another." It may be proper however, to observe, that the definition given by Cicero is better than that of Pythagoras, because the chief object of the philosopher is to ascertain the causes of things; and in this consists the difference between his studies and those of the natural historian, who merely enumerates phenomena, and arranges them into separate classes.

Truth, vi.
p. 8.

2
Its objects.

The principal objects of philosophy are, God, nature, and man. That part of it which treats of God is called theology; that which treats of nature, physics and metaphysics; and that which treats of man, logic and ethics. That these are not separate and independent sciences, but, as Bacon expresses (B), branches from the same trunk, we shall endeavour to show, after we have given, agreeably to our usual plan, a short history of philosophy from the earliest ages to the present day.

To attempt to assign an origin to philosophy, would

be ridiculous; for every man endeavours to ascertain the causes of those changes which he observes in nature; and even children themselves are inquisitive after that which produces the sound of their drums and their rattles. Children, therefore, and the most illiterate vulgar, have in all ages been philosophers. But the first people among whom philosophy was cultivated as a profession, was probably the Chaldeans. We certainly read of none earlier; for though we have more authentic accounts of the Hebrews than of any other nation of remote antiquity, and have reason to believe that no people was civilized before them, yet the peculiar circumstances in which they were placed, rendered all philosophical investigation to them useless, and even tended to suppress the very spirit of enquiry. The Egyptians indeed pretended to be the first of nations, and to have spread the blessings of religion and the light of science among every other people; but, from the earliest records now extant, there is reason to believe that the Chaldeans were a civilized and powerful nation before the Egyptian monarchy was founded.

History of
Philosophy

Of the Chaldean philosophy much has been said, but very little is known. Astronomy seems to have been their favourite study; and at the era of Alexander's conquest of their country, they boasted that their ancestors had continued their astronomical observations through a period of 470,000 years. Extravagant claims to antiquity have been common in all nations (C). Calisthenes, who attended the Macedonian conqueror, was requested by Aristotle to inform himself concerning the origin of science in Chaldea; and upon examining into the grounds of this report, he found that their observations reached no farther backwards than 1903 years, or 2234 years before the Christian era. Even this is a remoter antiquity than Ptolemy allows to their science: for he mentions no Chaldean observations prior to the era of Nabonassar,

3
Philosophy
of the Chal-
deans.

(A) The origin usually attributed to the term philosophy has been already assigned in the article PHILOLOGY. M. Chauvin gives it a term somewhat different. According to him, the term is derived from ποισις, desire or study, and σοφια, wisdom; and therefore he understands the word to mean the desire or study of wisdom; for (says he) Pythagoras, conceiving that the application of the human mind ought rather to be called study than science, set aside the appellation of wise as too assuming, and took that of philosopher.

(B) Convenit igitur partiri philosophiam in doctrinas tres; doctrinam de numine, doctrinam de natura, doctrinam de homine. Quoniam autem partitiones scientiarum non sunt lineis diversis similes, quæ coeunt ad unum angulum, sed potius ramis arborum, qui conjunguntur in uno trunco, qui etiam truncus ad spatium nonnullum integer est et continuus, antequam se partiat in ramos. De. aug. Scient. lib. iii. cap. 1.

(C) This claim of the Babylonians is thus rejected with contempt by Cicero; "Contemnamus Babylonios, et eos, qui e Caucaaso cæli signa servantes, numeris, et motibus, stellarum cursus persequuntur: Contemnemus, inquam, hos aut stultitia, aut vanitatis, aut imprudentia, qui 470 millia annorum, ut ipsi dicunt, monumentis comprehensa continent, et mentiri judicemus, nec seculorum reliquorum julianum, quod de ipsis futurum sit perimiscere. De Divinatione, lib. i. § 19.

or 747 years before Christ. That they cultivated something which they called philosophy at a much earlier period than this, cannot be questioned; for Aristotle*, on the credit of the most ancient records, speaks of the Chaldean magi as prior to the Egyptian priests, who were certainly men of learning before the time of Moses. For any other science than that of the stars, we do not read that the Chaldeans were famous; and this seems to have been cultivated by them merely as the foundation of judicial astrology. Persuading the multitude that all human affairs are influenced by the stars, and professing to be acquainted with the nature and laws of this influence, their *wife men* pretended to calculate nativities, and to predict good and bad fortune†. This was the source of idolatry and various superstitions; and while the Chaldeans were given up to such dotages, true science could not be much indebted to their labours. If any credit be due to Plutarch and Vitruvius, who quote Berosus, (see *BEROSUS*), it was the opinion of the Chaldean *wife men* that an eclipse of the moon happens when that part of its body which is destitute of fire is turned towards the earth. "Their cosmogony, as given by Berosus, and preserved by Syncellus, seems to be this, that all things in the beginning consisted of darkness and water; that a divine power dividing this humid mass, formed the world; and that the human mind is an emanation from the Divine nature‡.

The large tract of country which comprehended the empires of Assyria and Chaldea, was the first peopled region on earth. From that country, therefore, the rudiments of science must have been propagated in every direction through the rest of the world; but what particular people made the earliest figure, after the Chaldeans, in the history of philosophy, cannot be certainly known. The claim of the Egyptians is probably best founded; but as their science was the immediate source of that of the Greeks, we shall defer what we have to say of it on account of the connection between the parent and the offspring, and turn our attention from Chaldean to Indian philosophy, as it has been cultivated from a very early period by the Bramins and Gymnosophists. We pass over Persia, because we know not of any science peculiar to that kingdom, except the doctrines of the magi, which were religious rather than philosophical; and of them the reader will find some account under the words *MAGI*, *POLYTHEISM*, and *ZORASTER*.

From whatever quarter India received its wisdom, we are certain that its philosophers were held in high repute at a period of very remote antiquity, since they were visited by Pythagoras and other sages of ancient Greece, who travelled in pursuit of knowledge.

Yet they seem to have been in that early age, as well as at present, more distinguished for the severity of their manners than for the acquisition of science; and, as Dr Enfield observes, to have more resembled modern monks than ancient philosophers. The Bramins or Bramins, it is well known, are all of one tribe; and the most learned of them are in their own language called *Pandits* or *Pandits*. The Greek writers, however, mention a society called *Sarmanians*, who, voluntarily devoting themselves to the study of divine wisdom, gave up all private property, committed their children to the care of the state, and their wives to the protection of their relation. This society was supported at the public expence; and its members spent their time in contemplation, in conversation on divine subjects, or in acts of religion.

The philosophy of the Indians has indeed from the beginning been engrafted on their religious dogmas, and seems to be a compound of fanatic metaphysics and extravagant superstition, without the smallest seasoning of rational physics. Very unlike the philosophers of modern Europe, of whom a great part labour to exclude the agency of mind from the universe, the Pandits of Hindostan allow no powers whatever to matter, but introduce the Supreme Being as the immediate cause of every effect, however trivial. "Brehm, *the Spirit of God*, (says one of their most revered Bramins), is absorbed in self-contemplation. The same is the mighty Lord who is present in every part of space, whose omnipresence, as expressed in the *Reig Beid* or *Rigveda*, I shall now explain. Brehm is one, and to him there is no second; such is truly Brehm. His omniscience is self-inspired or self-intelligent, and its comprehension includes every possible species. To illustrate this as far as I am able; the most comprehensive of all comprehensive faculties is omniscience; and being self-inspired, it is subject to none of the accidents of mortality, *conception, birth, growth, decay, or death*; neither is it subject to passion or vice. To it the three distinctions of time, *past, present, and future*, are not. To it the three modes of being (*D*) are not. It is separated from the universe, and independent of all. This omniscience is named *Brehm*. By this omniscient Spirit the operations of God are enlivened. By this Spirit also the 24 powers (*E*) of nature are animated. How is this? As the eye by the sun, as the pot by the fire, as iron by the magnet (*F*) as variety of imitations by the mimic, as fire by the fuel, as the shadow by the man, as dust by the wind, as the arrow by the spring of the bow, and as the shade by the tree; so by this Spirit the world is endued with the powers of intellect, the powers of the will, and the powers of action; so that

on religion.

(D) To be awake, to sleep, and to be absorbed in a state of unconsciousness—a kind of trance.

(E) The 24 powers of nature, according to the Bramins, are the five elements, *fire, air, earth, water, and akash* (a kind of subtle æther); the five members of action, the *hand, foot, tongue, anus, and male-organ of generation*; the five organs of perception, the *ear, eye, nose, mouth, and skin*; the five senses which they distinguish from the organs of sensation; the three dispositions of the mind, *desire, passion, and tranquility*; and the power of *consciousness*.

(F) If the work from which this extract is quoted be of as great antiquity as Mr Halhed supposes, the Bramins must have been acquainted with the phenomena of *magnetism* at a much earlier period than any other philosophers of whom history makes mention.

History of
Philosophy

if it emanates from the heart by the channel of the ear, it causes the perception of sounds; if it emanates from the heart by the channel of the skin, it causes the perception of touch; if it emanates from the heart by the channel of the eye, it causes the perception of visible objects; if it emanates from the heart by the channel of the tongue, it causes the perception of taste; if it emanates from the heart by the channel of the nose, it causes the perception of smell. This also invigorating the five members of action, and invigorating the five members of perception, and invigorating the five elements, and invigorating the five senses, and invigorating the three dispositions of the mind, &c. causes the creation or the annihilation of the universe, while itself beholds every thing as an indifferent spectator*.”

* Preliminary Disc. to Halhed's Gentoo Laws.

6
Admits not the separate existence of matter, and

From this passage it is plain that all the motions in the universe, and all the perceptions of man, are, according to the Bramins, caused by the immediate agency of the Spirit of God, which seems to be here considered as the soul of the world. But it appears from some papers in the Asiatic researches, that the most profound of these oriental philosophers, and even the authors of their sacred books, believe not in the existence of matter as a separate substance, but hold an opinion respecting it very similar to that of the celebrated Berkeley. The Védantis (says Sir William Jones) unable to form a distinct idea of brute matter independent of mind, or to conceive that the work of Supreme Goodness was left a moment to itself, imagine that the Deity is ever present to his work, and constantly supports a series of perceptions, which in one sense they call *illusory*, though they cannot but admit the reality of all created forms, as far as the happiness of creatures can be affected by them.

This is the very immaterialism of Berkeley; and in proof that it is the genuine doctrine of the Bramins, the learned president quotes the *Bhāgavat*, which is believed to have been pronounced by the Supreme Being, and in which is the following sentence:

“Except the *first cause*, whatever may appear and may not appear, in the mind, know that to be the mind's *Māya*, or “delusion,” as light, as darkness.”

7
Teaches the metempsychosis.

We have shown elsewhere (see METAPHYSICS, n^o 269.) that the metaphysical doctrines of the Bramins, respecting the human soul, differ not from those of Pythagoras and Plato; and that they believe it to be an emanation from the great soul of the world, which, after many transmigrations, will be finally absorbed in its parent substance. In proof of their believing in the metempsychosis, Mr Halhed gives us the following translation of what (he says) is a beautiful stanza in the *Gēētā*: “As throwing aside his old clothes, a man puts on others that are new; so our lives, quitting the old, go to other newer animals.”

8
Physics of the Bramins.

From the Bramins believing in the soul of the world not only as the *sol agent*, but as the *immediate cause* of every motion in nature, we can hardly suppose them to have made any great progress in that science which in Europe is cultivated under the name of *physics*. They have no inducement to investigate the laws of nature; because, according to the first principles of their philosophy, which together with their religion, they believe to have been revealed from heaven, every phenomenon, however regular, or however anomalous,

is produced by the voluntary act of an intelligent mind. Yet if they were acquainted with the use of fire arms 4000 years ago, as Mr Halhed seems to believe, he who made that discovery must have had a very considerable knowledge of the powers of nature; for though gunpowder may have been discovered by accident in the East, as it certainly was in the West many ages afterwards, it is difficult to conceive how mere accident could have led any man to the invention of a gun. In astronomy geometry, and chronology too, they appear to have made some proficiency at a very early period. (See ASTRONOMY, n^o 4.) Their chronology and astronomy are indeed full of those extravagant fictions which seem to be essential to all their systems; but their calculations of eclipses, and their computations of time, are conducted upon scientific principles.

History of
Philosophy

2
Their astronomy

“It is sufficiently known, says Mr Davis † that † Asiatic Researches vol. ii. the Hindoo division of the ecliptic into signs, degrees, &c. is the same as ours; that their astronomical year is sidereal, or containing that space of time in which the sun departing from a star, returns to the same; that it commences on the instant of his entering the sign Aries, or rather the Hindoo constellation *Mésha*; that each astronomical month contains as many even days and fractional parts as he stays in each sign; and that the civil differs from the astronomical account of time only in rejecting those fractions, and beginning the year and month at sunrise, instead of the intermediate instant of the artificial day or night. Hence arises the unequal portion of time assigned to each month dependent on the situation of the sun's apsis, and the distance of the vernal equinoctial colure from the beginning of *Mésha* in the Hindoo sphere; and by these means they avoid those errors which Europeans, from a different method of adjusting their calendar by intercalary days, have been subject to.”

Mr Davis observes, that an explanation of these matters would have led him beyond his purpose, which was only to give a general account of the method by which the Hindoos compute eclipses, and to show that the science of astronomy is as well known among them now as ever it was among their ancestors. This he does very completely; but in the present short historical sketch, we can neither copy nor abridge his memoir. Suffice it to say, that he has shown the practical part of the Hindoo astronomy to be founded on mathematical principles; and that the learned Pandits appear to have truer notions of the form of the earth, and the economy of the universe than those which are ascribed to their countrymen in general.

The same writer shows likewise, that the prodigious duration which the Hindoos attribute to the world, is the result of a scientific calculation founded indeed on very whimsical principles. “It has been common with astronomers to fix on some epoch, from which, as from a radix, to compute the planetary motions; and the ancient Hindoos chose that point of time counted back, when, according to their notions as they had determined them, they must have been in conjunction in the beginning of *Mésha* or Aries, and coeval with which circumstance they supposed the *creation*. This, as it concerned the planets only, would have produced a moderate term of years compared with the enormous antiquity that will be hereafter stated.”

History of Philology

flated that having discovered a slow motion of the nodes and apses also, and taken it into the computation, they found it would require a length of time corresponding with 1955884850 years now expired, when they were so situated, and 2364115110 years more before they would return to the same situation again, forming together the grand anomalistic period denominated a *Calpa*, and fancifully assigned as the day of Brahma."

75
Strangeness of the universe.

But though the mathematical part of the astronomy of the Pandits is undoubtedly respectable, their physical notions of the universe are in the highest degree ridiculous and extravagant. In the Vedas and Puranas, writings of which no devout Hindoo can dispute the divine authority, eclipses are said to be occasioned by the intervention of the monster *Rahu*; and the earth to be supported by a series of animals. "They suppose (says Mr Halhed) that there are 14 spheres, seven below and six above the earth. The seven inferior worlds are said to be altogether inhabited by an infinite variety of serpents, described in every monstrous figure that the imagination can suggest. The first sphere above the earth is the immediate vault of the visible heavens, in which the sun, moon, and stars, are placed. The second is the first paradise, and general receptacle of those who merit a removal from the lower earth. The third and fourth are inhabited by the souls of those men who, by the practice of virtue and dint of prayer have acquired an extraordinary degree of sanctity. The fifth is the reward of those who have all their lives performed some wonderful act of penance and mortification, or who have died martyrs for their religion. The highest sphere is the residence of Brahma and his particular favourites, such as those men who have never uttered a falsehood during their whole lives, and those women who have voluntarily burned themselves with their husbands. All these are absorbed in the divine essence."

11
Ethics of the Hindoos.

On ethics, the Hindoos have nothing that can be called philosophy. Their duties, moral, civil, and religious, are all laid down in their *Vedas* and *Shasters*; and enjoined by what they believe to be divine authority, which supercedes all reasoning concerning their fitness or utility. The business of their Pandits is to interpret those books, which are extremely ancient, and written in a language that has long been unintelligible to every other order of men; but no Pandit will alter the text however impossible to be reconciled to principles established in his own practice of astronomy. On such occasions the usual apology for their sacred books is, that "such things may have been so formerly, and may be so still; but that for astronomical purposes, astronomical rules must be followed."

* David's Memoir, Asiatic Researches, vol. ii.

The great duties of morality have been prescribed in every religious code; and they are not overlooked in that of the Hindoos, though the highest merit that a Bramin can have consists in voluntary acts of abstinence and mortification, and in contempt of death.

12
Philosophy of the Arabians and Chinese.

Of the ancient philosophy of the Arabians and Chinese nothing certain can be said; and the narrow limits of such an abstract as this; do not admit of our mentioning the conjectures of the learned, which contradict each other, and are all equally groundless.

that the Chinese had even a theory by which they foretold eclipses (see *ASTRONOMY*, n^o 2, 3.); but there is reason to believe that the Arabians, like other people in their circumstances, were nothing more than judicial astrologers, who possessed not the smallest portion of astronomical science.

History of Philosophy

Pliny makes mention of their magi, whilst later writers tell us, that they were famous for their ingenuity in solving enigmatical questions, and for their skill in the arts of divination: but the authors of Greece are silent concerning their philosophy; and there is not an Arabian book of greater antiquity than the Koran extant. (See *PHILOLOGY*, Section II.)

Leaving therefore regions so barren of information, let us pass to the Phœnicians, whose commercial celebrity has induced many learned men to allow them great credit for early science. If it be true, as seems highly probable, that the ships of this nation had doubled the Cape and almost encompassed the peninsula of Africa long before the era of Solomon (See *OPHIC*, n^o 10), we cannot doubt but that the Phœnicians had made great proficiency in the art of navigation, and in the science of astronomy, at a period of very remote antiquity. Nor were these the only sciences cultivated by that ancient people: the learned Cudworth has, in our opinion, sufficiently proved that *Moschus* or *Mochus* a Phœnician, who, according to Strabo, flourished before the Trojan war, was the author of the atomic philosophy afterwards adopted by Leucippus, Democritus, and others among the Greeks; and that it was with some of the successors of this sage that Pythagoras, as Jamblicus tells us, conversed at Sidon, and from them received his doctrine of *Monads*. (See *PYTHAGORAS*). Another proof of the early progress of the Phœnicians in philosophy may be found in the fragments of their historian Sanchoniathon which have been preserved by Eusebius.

13
Early science of the Phœnicians

We are indeed aware that men of great celebrity have called in question the authenticity of these fragments, and even the very existence of such a writer as Sanchoniathon; but for this scepticism we can discover no foundation (See *SANCHONIATHON*). His history may have been interpolated in some places by the translator Philo-Byblius; but Porphyry, Eusebius, and Theodoret, speak of it as a work of undoubted credit, and affirm that its author flourished before the Trojan war. Now this ancient writer teaches that, according to the *wise men* of his country, all things arose at first from the necessary agency of an active principle upon a passive chaotic mass which he calls *mot*. This chaos Cudworth thinks was the same with the elementary *water* of Thales, who was also of Phœnician extraction; but Mosheim justly observes that it was rather *dark air*, since Philo translates it *αἴρ ἄσφαδρα*. Be this as it may, nothing can be more evident than that the Phœnicians must have made some progress in what must surely be considered as philosophy, however false, so early as the era of Sanchoniathon; for speculations about the origin of the world never occur to untaught barbarians. Besides Moschus and Sanchoniathon, Cadmus, who introduced letters into Greece may undoubtedly be reckoned among the Phœnician philosophers; for though it is not pretended that the alphabet was of his invention, and though

† Prep. Ev.

History of Philosophy though it is by no means certain that the Greeks, at the time of his arrival among them, were wholly destitute of alphabetic characters (See PHILOLOGY, n^o 130.); yet the man who could prevail with illiterate savages to adopt the use of strange characters, must have been a great master of the science of human nature. Several other Phœnician philosophers are mentioned by Strabo; but as they flourished at a later period, and philosophised after the systematic mode of the Greeks, they fall not properly under our notice. We pass therefore to the philosophy of Egypt.

14 Egyptian philosophy

It has been already observed that the Egyptians boasted of being the first of nations, and the authors of all the science which in separate rays illuminated the rest of the world. But though this claim was undoubtedly ill-founded, their high antiquity and early progress in the arts of civil life cannot be controverted. The Greeks with one voice confess that all their learning and wisdom came from Egypt, either imported immediately by their own philosophers, or brought through Phœnicia by the fingers of the east; and we know from higher authority than the histories of Greece, that at a period so remote as the birth of Moses, the wisdom of the Egyptians was proverbially famous. Yet the History of Egyptian learning and philosophy, though men of the first eminence both ancient and modern have bestowed much pains in attempts to elucidate it, still remains involved in clouds of uncertainty. That they had some knowledge of physiology, arithmetic, geometry, and astronomy, are facts which cannot be questioned; but there is reason to believe that even these sciences were in Egypt pushed no further than to the uses of life. That they believed in the existence of incorporeal substances is certain; because Herodotus assures us that they were the first asserters of the immortality, pre-existence, and transmigration of human souls, which they could not have been without holding those souls to be at least *incorporeal*, if not *immaterial*.

The author of Egyptian learning is generally acknowledged to have been *Thoth*, *Theut* or *Taut*, called by the Greeks *Hermes*, and by the Romans *Mercury*; but of this personage very little is known. Diodorus Siculus says that he was chief minister to Osiris, and that he improved language, invented letters, instituted religious rites, and taught astronomy, music, and other arts. The same thing is affirmed by *Sanchoniatho*, whose antiquity has been already mentioned; by *Manetho* an Egyptian priest, who flourished during the reign of Ptoemy Philadelphus; and by Plato whose authority, as he resided long in Egypt, and was himself an eminent philosopher, is perhaps more to be depended upon than that of the other two. In the Philebus we are told that Thoth was the inventor of letters; and lest we should suppose that by those letters nothing more is meant than picture writing or symbolical hieroglyphics, it is added that he

distinguished between vowels and consonants, and assigning the number of each. The same philosopher, in his Phædrus, ascribes to Thoth the invention of arithmetic, geometry, astronomy, and Egyptian learning; and subjoins a dissertation on the difference between him and *Thamus* concerning the use of the newly invented letters. Thoth boasted that the inventor, by aiding memory, would greatly contribute to the progress of science; whilst the monarch contended, that it would enervate men's natural faculties by making them trust to written characters without exerting the powers of their own minds.

All this, if real, must have happened before the era of Moses: and since it is almost certain that alphabetic characters were in use prior to the *exod* of the Israelites from Egypt (See PHILOLOGY, n^o 24, 25.) we may as well allow the invention to Thoth, as give it to an earlier author of unknown name. That arithmetic, geometry, and astronomy, were cultivated in Egypt from the most remote antiquity, is affirmed by all the ancients, and made in the highest degree probable by the situation of the country. The first elements of astronomy have certainly been discovered by various nations, whose habits of life led them to the frequent observation of the heavens; and it is observed by Cicero, that the Egyptians and Babylonians, dwelling in open plains where nothing intercepted the view of the heavenly bodies, naturally devoted themselves to the study of that science. The annual overflowing of the Nile, which broke up the boundaries of their lands, would lay the Egyptians under the necessity of adopting some method of settling those boundaries anew; and necessity we know to be the parent of invention. Hence their early acquaintance with practical geometry cannot well be doubted. Their custom of embalming their dead, and the perfection to which they carried that art (c), shows infallibly their knowledge of the properties of natural substances, and gives some reason to believe that they were not altogether strangers to anatomy; but if we allow them to have been at this early period anatomists acquainted with the powers of drugs, we can hardly refuse them some skill in the art of physic, which they themselves traced up to their gods and demigods, to *Serapis*, *Ihs*, and her son *Horus* or *Apollo*.

The art of alchymy has been said to have been known by the ancient Egyptians; and from the author of the Egyptian philosophy it has been called the *Hermetic art*. But though this is unquestionably a fiction, there is evidence that they were possessed of one art which is even yet a *desideratum* in the practice of chemistry. "Moses (we are told †) took the golden calf, which his brother had made for idolatrous purposes, and burnt it in the fire, and ground it to powder, and strowed it on the water, and made the children of Israel drink of it." Had this fact been related by Herodotus or Diodorus Siculus, it would

† Exod. xlii. 20.

(c) It is true that the dissection of some mummies has lessened the high opinion long entertained of the skill of the ancient Egyptians in the art of embalming; yet it must be granted that their knowledge of antiseptic drugs was great, since it is now certainly known even from these dissections, that by means of such drugs they contrived to preserve rags of cloth from corruption for upwards of 3000 years.

History of
Philosophy

have been deemed sufficient evidence that the Egyptians were even at that early period no strangers to the art of chemistry; and surely the evidence should not be the worse for coming from the pen of the Hebrew lawgiver, who was himself educated in the court of Egypt.

15
Not carried
to high
perfection.

But though it is thus evident that the rudiments of almost every useful science were known in Egypt from the remotest antiquity, it does not appear that any of them was carried to a great degree of perfection, unless perhaps chemistry alone must be excepted. One would think that no science could have been more indispensably requisite to them than geometry. And yet though Pythagoras is said to have spent 22 years in Egypt studying that science and astronomy, he himself discovered (H) the famous 47th Prop. of Euclid's first book after his return to Samos. This, though a very useful, is yet a simple theorem; and since it was not reached by the Egyptian geometry, we cannot suppose that those people had then advanced far in such speculations. The same conclusion must be drawn with respect to astronomy; for Thales is said to have been the first that calculated an eclipse of the sun; and we nowhere read that the Egyptians pretended to dispute that honour with him. To this it may be replied, that Pythagoras was in Egypt undoubtedly taught the true constitution of the solar system, and what is more extraordinary, the doctrine of comets in particular, and of their revolutions, like the other planets, round the sun (I). We grant that he was taught all this; but it was not scientifically, but dogmatically, as facts which the priests had received by tradition from their early ancestors, and of which they had never questioned the truth nor inquired into the reasons. Of this we need no better proof than that the Pythagorean system of the sun was totally ne-

16
Their
knowledge
of the solar
system.

glected by the Greeks as soon as they began to frame hypotheses and to speculate in philosophy (K).

History of
Philosophy

But it may seem strange, and it certainly is so, that the Egyptian priests, in the days of Pythagoras, should have preserved to great a discovery of their ancestors, and at the same time have totally forgotten the principles and reasoning which led to a conclusion apparently contrary to the evidence of sense. This is a difficulty which we pretend not to remove, though the fact which involves it seems to be beyond the reach of controversy. Perhaps the following observations may throw upon it a feeble light. According to Manetho, the written monuments of the first Theb were lost or neglected in certain civil revolutions or natural calamities which beset the kingdom of Egypt. After many ages great part of them were recovered by an ingenious interpretation of the symbols which he had inscribed upon ancient columns; and the man who made this interpretation was called the second Theb or *Hermes Trismegistus*. But *thrice illustrious* as this personage was, it is at least possible that he may have been much inferior to the former Hermes, and have read his writings and transcribed his conclusions without being able to comprehend the principles or reasoning which led to those conclusions. Any man who understands Latin might translate into his own tongue the conclusions of Newton; but much more would be requisite to make him comprehend the demonstrations of his sublime geometry. By what mode of reasoning the first Hermes (L) was led to the true idea of the solar system, or whether it was by reasoning at all, cannot now be known; but it seems very evident, that when the intercourse between the Egyptians and Greeks first commenced, the wisdom of the former people consisted chiefly in the science of legislation and civil policy, and that the philosopher,

(H) This discovery he claimed; and his claim was admitted by the Greek writers without having been directly controverted since. An excellent mathematician, however, has lately shown that the equality between the square of the hypotenuse of a right angled triangle, and the sum of the squares on the other two sides, was known to the astronomers of India at a period long prior that of Pythagoras. Notwithstanding this, it is certainly possible that the sage of Samos may have made the discovery himself, though we think the contrary much more probable; for we agree with the able writer already mentioned, that Pythagoras who is generally believed to have conversed with Indian brachmans as well as Egyptian priests, may have derived from them "some of the solid as well as the visionary speculations with which he delighted to instruct or amuse his disciples." See *Transactions of the Royal Society of Edinburgh*, vol. ii. Memoir xi. i. Physic Class.

(I) This is recorded by Aristotle and Plutarch; and thus expressed by Ammianus Marcellinus.—"Stellas quasdam, ceteris finites, quarum ortus orbitalisque, quibus sint temporibus præstitum humanis mentibus ignorari. Lib. xxv. cap. 10.

(K) *Ætas* in supremis mundi partibus immotas persistere, et planetas his inferiores circa solem revolvi, terram pariter moveri cursu annuo, diurno vero circa axem propriam, et solem ceu locum universi in omnium centro quiescere, antiquissima fuit philosophantium sententia. Ab Ægyptiis autem astrorum antiquissimis observationibus propagatam esse hæc sententia iam verisimile est. Et etiam ab illis et a gentibus conterminis ad Græcos, gentem magis philologicam quam philosophicam, philosophia omnis antiquior juxta et senier manifeste videtur. Subinde docuerunt Anaxagoras, Democritus, et alii nonnulli, terram in centro mundi immotam stare, et astra omnia in occasum, aliqua celerius, alia tardius moveri, idque in spatiis liberissimis. Tamque orbis solidi postea ab Eudoxo, Calippo, Aristotele, introducti sunt; deinde inde philosophia primitus introducta, et novis Græcorum commentis paulatim prevalentibus. Quibus *vicibus* antiqui planetas in spatiis liberis retineri, deque cursu rectilineo perpetuo retinatas in orbem regulariter agi docuere, non constat. *Newton de Mundi Systemate*.

(L) Some authors, deeply skilled in the Hebrew language, have thought that the true system of the sun and planets may be perceived in the Scriptures of the Old Testament, and that it is only from the ignorance or carelessness of the translators that it does not appear in the English bible and other versions. The writer of this article con-

fesses

History of Philosophy pher, the divine, the legislator, and the poet, were all united in the same person. Their cosmogony (for all the ancients who pretended to science framed cosmogonies) differed little from that of the Phœnicians already mentioned. They held that the world was produced from chaos by the energy of an intelligent principle: and they likewise conceived that there is in nature a continual tendency towards dissolution. In Plato's *Timæus*, an Egyptian priest is introduced describing the destruction of the world, and asserting that it will be effected by means of water and fire. They conceived that the universe undergoes a periodical conflagration; after which all things are restored to their original form, to pass again through a similar succession of changes.

17
Their moral science. Enfield's Hist. of Philosophy
“Of preceptive doctrine the Egyptians had two kinds, the one sacred, the other vulgar. The former, which respected the ceremonies of religion and the duties of the priests, was doubtless written in the sacred books of *Hermes*, but was too carefully concealed to pass down to posterity. The latter consisted of maxims and rules of virtue, prudence, or policy. *Diodorus Siculus* relates many particulars concerning the laws, customs, and manners of the Egyptians; whence it appears that superstition mingled with and corrupted their notions of morals. It is in vain to look for accurate principles of ethics among an ignorant and superstitious people. And that the ancient Egyptians merited this character is sufficiently evident from this single circumstance, that they suffered themselves to be deceived by impostors, particularly by the professors of the fanciful art of astrology; concerning whom *Sextus Empiricus* justly remarks, that they have done much mischief in the world, by enslaving men to superstition, which will not suffer them to follow the dictates of right reason.” See EGYPT, MYSTERIES, MYTHOLOGY, &c.

18
Grecian philosophy.
From Egypt and Phœnicia philosophy passed into Greece; where it was long taught without system, as in the countries from which it was derived. *Phœneus*, *Cecrops*, *Cadmus*, and *Orpheus*, were among the earliest instructors of the Greeks; and they inculcated Egyptian and Phœnician doctrines in detached maxims, and enforced them, not by strength of argument, but by the authority of tradition. Their cosmogonies were wholly Phœnician or Egyptian disguised under Grecian names; and they taught a future state of rewards and punishments. The planets and the moon *Orpheus* conceived to be habitable worlds, and the stars to be fiery bodies like the sun: but he taught that they are all animated by divinities; an opinion which prevailed both in Egypt and the east: and it does not appear that he gave any other proof of his doctrines than a confident assertion that they were derived from some god. See ORPHEUS.

Hitherto we have seen philosophy in its state of infancy and childhood, consisting only of recollection of sententious maxims and traditionary opinions; but among the Greeks, an ingenious and penetrating people, it soon assumed the form of profound speculation and systematic reasoning. Two eminent philosophers arose nearly at the same period, who may be considered as the parents not only of Grecian science, but of almost all the science which was cultivated in Europe prior to the era of the great Lord Bacon: These were *Thales* and *Pythagoras*; of whom the former founded the Ionic school and the latter the Italic: from which two sprang the various sects into which the Greek philosophers were afterwards divided. A bare enumeration of these sects is all that our limits will admit of; and we shall give it in the perspicuous language and just arrangement of *Dr Enfield*, referring our readers for a fuller account than we can give of their respective merits to his abridged translation of *Brucker's* history.

19
The Ionic school.
Of the Ionic School were, 1. The Ionic sect proper, whose founder *Thales* had as his successors *Anaximenes*, *Anaxagoras*, *Diogenes Apolloniates*, and *Archelaus*. 2. The Socratic school, founded by *Socrates*, the principal of whose disciples were *Xenophon*, *Æschines*, *Simon*, *Cebes*, *Aristippus*, *Phædo*, *Euclid*, *Plato*, *Antisthenes*, *Critias*, and *Alcibiades*. 3. The Cyrenaic sect, of which *Aristippus* was the author: his followers were, his daughter *Arete*, *Hegesias*, *Anicerris*, *Theodorus*, and *Bion*. 4. The Megaric or Eristic sect, formed by *Euclid* of *Megara*; to whom succeeded *Eubulides*, *Diodorus*, and *Stilpo*, famous for their logical subtlety. 5. The Eliac or Eretriac school, raised by *Phælo* of *Elis*, who though he closely adhered to the doctrine of *Socrates*, gave name to his school. His successors were *Plititanus* and *Menedemus*; the latter of whom, being a native of *Eretria*, transferred the school and name to his own country. 6. The Academic sect, of which *Plato* was the founder. After his death, many of his disciples deviating from his doctrine, the school was divided into the old, new, and middle academics. 7. The Peripatetic sect, founded by *Aristotle*, whose successors in the *Lyceum* were *Theophrastus*, *Strato*, *Lycon*, *Aristo*, *Critolaus*, and *Diodorus*. Among the Peripatetics, besides those who occupied the chair, were also *Dicæarchus*, *Eudemus*, and *Eudemus Phalerens*. 8. The Cynic sect, of which the author was *Antisthenes*, whom *Diogenes*, *Onesicritus*, *Crates*, *Nectrocles*, *Menippus*, and *Menedemus*, succeeded. In the list of Cynic philosophers must also be reckoned *Hipparchia*, the wife of *Crates*. 9. The Stoic sect, of which *Zeno* was the founder. His successors in the porch were *Percus*, *Ariko* of *Chios*, *Herillus*, *Sphærus*, *Cleanthes*,
4 D 2 Chry-

esses that his knowledge of the Hebrew is very limited, which is probably the reason that to him the arguments of these men appear weak and their criticisms fanciful. No man, however, has a higher veneration than he for the sacred volume, which he believes to have been given for nobler purposes than to teach its readers the science of astronomy; but could the principles of that science be found in it, he should be strongly inclined to think that the first *Thoth* was *Joseph*, and that the monarch to whom he was minister was the far-famed *Osiris*. Were there any solid foundation for this supposition, it would be easy to conceive how *Thoth* acquired his science, and how the Egyptian priests might retain just notions of the solar system in general, long after they had forgotten the evidence upon which he communicated those notions to their ancestors.

History of Philosophy

The Italic school

Chryſippus, Zeno of Tarſus, Diogenes the Babylonian, Antipater, Panætius, and Poſidonius.

Of the ITALIC SCHOOL were, 1. The Italic ſect proper: it was founded by Pythagoras, a diſciple of Pherecydes. The followers of Pythagoras were Ariftæus, Mæſarchus, Alcmaeon, Ecphantus, Hippo, Emejedæes, Epicharmus, Ocellus, Timæus, Archytas, Hippaſtus, Philolaus, and Eudoxus. 2. The Eleatic ſect, of which Xenophanes was the author: his ſucceſſors, Parmenides, Meliſſus, Zeno, belonged to the metaphyſical claſs of this ſect; Leucippus Democritus, Protagoras, Diagoras, and Anaxarchus, to the phyſical. 3. The Heraclitean ſect, which was founded by Heraclitus, and ſoon afterwards expired; Zeno and Hippocrates philoſophiſed after the manner of Heraclitus, and other philoſophers borrowed freely from his ſyſtem. 4. The Epicurean ſect, a branch of the Eleatic, had Epicurus for its author; among whoſe followers were Metrodorus, Polyænus, Hermachus, Polylitratuſ, Baſilides, and Protarchus. 5. The Pyrrhonic or Sceptic ſect, the parent of which was Pyrrho: his doctrine was taught by Timon the Phiaſian; and after ſome interval was continued by Ptolemy a Cyrenean, and at Alexandria by Zenoſidemus.

Of the peculiar doctrines of theſe ſects, the reader will in this work find a ſhort account either in the lives of their reſpective founders, or under the names of the ſects themſelves. We ſhall only obſerve at preſent, that though many of them were undoubtedly abſurd, and many wicked, it would yet perhaps be going too far to ſay with ſome, that the philoſophy of Greece became impious under Diagoras, vicious under Epicurus, HYPOCRITICAL UNDER ZENO, impudent under Diogenes, covetous under Demochares, voluptuous under Metrodorus, fantaſtical under Crates, ſcurrilous under Menippus, licentious under Pyrrho, and quarrelſome under Cleanthes. Of the truth of this heavy charge every reader muſt judge for himſelf. We are ſtrongly inclined to think, that there were virtues and vices peculiar to each ſect; and that the ſects themſelves had an affinity more or leſs direct with the different temperaments of man; whence the choice of ſectators often depended on phyſical influence, or a peculiar diſpoſition of their organs. Nothing appears more natural than that thoſe men who were born with great force of mind and ſtrong nerves ſhould diſcover a predilection for ſtoiciſm; while mortals, endowed by nature with more delicacy of fibres and keener ſenſibility, ſhed firſt refuge to the myrtles of Epicurus. People, whoſe temperaments partook of no extremes, were always inclined either for the Lyceum or the academy. Such as poſſeſſed ſolidity of underſtanding ranged themſelves with Ariſtotle; and thoſe who had only genius, or even pretenſions to that endowment, went to augment the crowd of Platonists."

All the ſyſtematical philoſophers, however, purſued their inquiries into nature by nearly the ſame method. Of their philoſophy as well as of ours, the univerſe, with all that it contains, was the vaſt object; but the individual things which compoſe the univerſe are infinite in number and ever changing; and therefore, according to an eſtabliſhed maxim of theirs, incapable of being the ſubjects of human ſcience *. To reduce this infinite, and to fix thoſe fleeting beings, they eſtabliſhed certain definite arrangements or claſſes,

to ſome of which every thing paſt, preſent, or to come, might be referred; and having aſcertained, as they thought, all that could be affirmed or denied of theſe claſſes, they proved, by a very ſhort proceſs of ſyllogiſtic reaſoning, that what is true of the claſs muſt be true of every individual comprehended under it. The moſt celebrated of theſe arrangements is that which is known by the name of *cat'gories*; which Mr Harris thinks at leaſt as old as the era of Pythagoras, and to the forming of which mankind would, in his opinion, be neceſſarily led by the following conſiderations: Every ſubject of human thought is either *ſubſtance* or *attribute*; but *ſubſtance* and *attribute* may each of them be modified under the different characters of *uni-verſal* or *particular*. Hence there ariſes a quadruple arrangement of things into *ſubſtance uni-verſal* and *ſubſtance particular*; into *attribute uni-verſal* and *attribute particular*; to ſome one of which four not only our words and ideas, but every individual of that infinite multitude of things which compoſe the univerſe may be reduced. This arrangement, however, the learned author thinks too limited; and he is of opinion, that, by attending to the ſubſtances with which they were ſurrounded, the Grecian ſchools muſt ſoon have diſtinguiſhed between the attributes *eſſential* to all ſubſtances and thoſe which are only *circumſtantial*; between the attributes proper to *natural* ſubſtances or bodies, and thoſe which are peculiar to *intelligible* ſubſtances or minds. He likewiſe thinks, that the *time* and *place* of the exiſtence of ſubſtances not preſent, muſt ſoon have attracted their attention; and that in conſidering the place of this or that ſubſtance, they could hardly avoid thinking of its *poſition* or *ſituation*. He is of opinion, that the ſuperinduction of one ſubſtance upon another would inevitably ſuggeſt the idea of *cloathing* or *habit*, and that the variety of *co-exiſting ſubſtances* and *attributes* would diſcover to them another attribute, viz. that of *relation*. Inſtead therefore of conſining themſelves to the ſimple diſtinction of *ſubſtance* and *attribute*, they divided *attribute* itſelf into nine diſtinct ſorts, ſome *eſſential* and others *circumſtantial*; and thus by ſetting ſubſtance at their head, made ten *comprehenſive* and *uni-verſal genera*, called, with reference to their Greek name, *categories*, and with reference to their Latin name, *predicaments*. Theſe categories are, SUBSTANCE, QUALITY, QUANTITY, RELATION, ACTION, PASSION, WHEN, WHERE, POSITION, and HABIT; which, according to the ſyſtematical philoſophy of the Greeks, comprehend every human ſcience and every ſubject of human thought. *Hiſtory*, natural and civil, ſprings, ſays Mr Harris, out of SUBSTANCE; *mathematics* out of QUANTITY; *optics* out of QUALITY and QUANTITY; *medicine* out of the *ſame*; *aſtronomy* out of QUANTITY and MOTION; *muſic* and *mechanics* out of the *ſame*; *painting* out of QUALITY and SITE; *eticks* out of RELATION; *chronology* out of WHEN; *geography* out of WHERE; *electricity*, *magnetism*, and *attraction*, out of ACTION and PASSION; and ſo in other inſtances.

To theſe categories, conſidered as a mere arrangement of ſcience, we are not inclined to make many objections. The arrangement is certainly not complete; but this is a matter of comparatively ſmall importance; for a complete arrangement of ſcience cannot, we believe, be formed. The greateſt objection to the categories ariſes from the uſe that was made of them by almoſt

History of Philosophy

22 The categories.

Plato's Philosophical considerations, &c.

21 Grecian mode of philosophizing.

* Boeth in Encic. et Philoſ. lib. i.

History of almost every philosopher of the Grecian schools; for those sages having reduced the objects of all human science to ten general heads or general terms, instead of setting themselves to inquire by a painful induction into the nature and properties of the real objects before them, employed their time in conceiving what could be predicated of *substance* in general, of this or that *quality*, *quantity*, *relation*, &c. in the abstract; and they soon found, that of such general conception as the *categories* there are but five *predicables* or classes of *predicates* in nature. The first class is that which the *predicate* is the *genus* of the *subject*; the second that in which it is the *species* of the *subject*; the third, is when the *predicate* is the *specific difference* of the *subject*; the fourth, when it is a *property* of the *subject*; and the fifth, when it is something *accidental* to the *subject*; (see LOGIC, Part II. chap. ii. and iii.) Having proceeded thus far in their system, they had nothing to do with individuals but to arrange them under their proper categories, which was commonly done in a very arbitrary manner; and then, with the formality of a syllogism, to predicate of each the predicable of the genus or species to which it belonged. But by this method of proceeding, it is obvious that no progress whatever could be made in physical, metaphysical, or ethical science; for if the individual truly belongs to the category under which it is arranged, we add nothing to our stock of knowledge by affirming or denying of it what we had before affirmed or denied of the whole genus: and if it belong not to the category under which we arrange it, our syllogising will only give the appearance of proof to what must, from the nature of things, be an absolute falsehood. It is only by experiments made on various substances apparently of the same kind that they can be certainly known to belong to the same category; and when this is done, all syllogistic reasoning from the genus to the species, and from the species to the individual, is but solemn trifling, as every proposition in this retrograde course takes for granted the thing to be proved.

Yet this mode of philosophizing spread from Greece almost over the whole world. It was carried by Alexander into Asia, by his successors into Egypt; and it found its way to Rome after Greece became a province of the empire. It was adopted by the Jews, by the fathers of the Christian church, by the Mohammedan Arabs during the caliphate, and continued to be cultivated by the schoolmen through all Europe, till its futility was exposed by Lord Bacon (M). The professors of this philosophy often displayed great acuteness; but their systems were built on mere hypotheses, and supported by syllogistic wrangling. Now and then indeed a superior genius, such as Alhazen and our countryman Roger Bacon, broke through the trammels of the schools, and, regardless of the authority of the Stagyrice and his *caegories*, made real discoveries in physical science by experiments judiciously conducted on individual substances (see BACON (Roger); and

OPICS, n^o 6.); but the science in repute still continued to be that of *Generals*.

It was indeed a combination of absurd metaphysics with more absurd theology: and that which is properly called *physics*, had in Europe no place in a liberal education from the end of the eighth century to the end of the fourteenth. Towards the beginning of this period of darkness, the whole circle of instruction, or the liberal arts as they were called, consisted of two branches, the *trivium* and the *quadrivium*; of which the former comprehended *grammar*, *rhetoric*, and *dialectics*; the latter *music*, *arithmetic*, *geometry*, and *astronomy*, to which was added about the end of the eleventh century the study of a number of *metaphysical subtilties* equally useless and unintelligible.

Hitherto the works of the ancient Greek philosophers had been read only in imperfect Latin translations; and before the scholastic system was completely established, Plato and Aristotle had been alternately looked up to as the oracle in science. The rigid schoolmen, however, universally gave the preference to the Stagyrice, because his analysis of body into matter and form is peculiarly calculated to keep in countenance the most incredible doctrine of the Romish church (see TRANSUBSTANTIATION): and upon the revival of Greek learning, this preference was continued after the school philosophy had begun to fall into contempt, on account of much useful information contained in some of his writings on subjects of natural history, and his supposed merit as a natural philosopher. At last the intrepid spirit of Luther and his associates set the minds of men free from the tyranny of ancient names, as well in human science as in theology; and many philosophers sprung up in different countries of Europe, who professed either to be *celestics*, or to study nature, regardless of every authority but that of reason. Of these the most eminent beyond all comparison was Francis Bacon Lord Verulam.

This illustrious man having read with attention the writings of the most celebrated ancients, and made himself master of the sciences which were then cultivated, soon discovered the absurdity of pretending to account for the phenomena of nature by syllogistic reasoning from hypothetical principles; and with a boldness becoming a genius of the first order, undertook to give a new chart of human knowledge. This he did in his two admirable works, intitled, 1. *De dignitate et augmentis scientiarum*; and, 2. *Novum organum Scientiarum*; five *Julcia vera de interpretatione Natura*. In the former of these works, he takes a very minute survey of the whole circle of human science, which he divides into three great branches, *history*, *poetry*, and *philosophy*, corresponding to the three faculties of the mind, *memory*, *imagination*, and *reason*. Each of these general heads is subdivided into smaller branches, and reflections are made upon the whole, which, though we can neither copy nor abridge them, will amply reward

thod of in-
quiry.

would the perusal of the attentive reader. The purpose of the *Novum Organum* is to point out the proper method of interpreting nature; which the author shows can never be done by the logic which was then in fashion, but only by a painful and fair induction. "Homo nature minister (says he) et in eipres tantum facit et intelligit, quantum de naturæ ordine re, vel mente observaverit; nec amplius scit aut potest. Syllogismus ad principia scientiarum non adhibetur, ad media axiomata frustra adhibetur, cum sit substatu naturæ longe impar. Assensum itaque contrahit, non res. Syllogismus ex propositionibus constat, propositiones ex verbis, verba notionum tenere sunt. Itaque si notionis ipse (id quod basis rei est) confusa sit et temere a rebus abstractæ, nihil in eis quæ superstruuntur, est similitudinis. Itaque spes est una in *inductione vera*."

To hypotheses and preconceived opinions, which he calls *idolothabiti*, this great man was not less inimical than to syllogisms; and since his days almost every philosopher of eminence, except Descartes and his followers (see DESCARTES and CARTESIANS), has professed to study nature according to the method of induction so accurately laid down in the *Novum Organum*. On this method a few improvements have perhaps been made; but notwithstanding these, Lord Bacon must undoubtedly be considered as the author of that philosophy which is now cultivated in Europe, and which will continue to be cultivated as long as men shall have more regard for matters of fact than for hypothetical opinions. Of this mode of philosophizing we shall now give a short, though we hope not inaccurate, view, by stating its objects, comparing it with that which it superseded, explaining its rules, and pointing out its uses; and from this view it will appear, that its author shares with Aristotle the empire of science.

28
View of his
philosophy.

THE universe, that unbounded object of the contemplation, the curiosity and the researches of man, may be considered in two different points of view.

In the first place, it may be considered merely as a collection of existences, related to each other by means of resemblances and distinction, situation, succession, and derivation, as making parts of a whole. In this view it is the subject of pure description.

To acquire an acquaintance with, or a knowledge of, the universe in this point of view, we must enumerate all the beings in it, mention all their sensible qualities, and mark all these relations for each. But this would be labour immense; and when done, an unaffordable chaos. A book containing every word of a language would only give us the materials, so to speak, of this language. To make it comprehensible, it must be put into some form, which will comprehend the whole in a small compass, and enable the mind to pass easily from one word to another related to it. Of all relations among words, the most obvious are those of resemblance and derivation. An etymological dictionary, therefore, in which words are classed in consequence of their resemblances, and arranged by means of their derivative distinctions, will greatly facilitate the acquisition of the language.

Just so in nature: The objects around us may be grouped by means of their resemblance, and then ar-

ranged in those groups by means of their distinctions and other relations. In this classification we are enabled to proceed by means of our faculty of abstracting our attention from the circumstances in which things differ, and turning it to those only in which they agree. By the judicious employment of this faculty we are able not only to distribute the individual; into classes, but also to distribute those classes into others still more comprehensive, by discovering circumstance of resemblance among them: for the fewer the circumstances are which concur to form that resemblance which has engaged our attention, the greater is the number of dissimilar circumstances which are neglected; and the more extensive will be the class of individuals in which the resemblance is observed. Thus a number of individuals resembling each other in the single circumstance of life, composes the most extensive KINGDOM of ANIMALS. If it be required, that they shall further resemble in the circumstance of having feathers, a prodigious number of animals are excluded, and we form the inferior class of BIRDS. We exclude a great number of birds, by requiring a further similarity of web feet, and have the order of ANSERES. If we add lingua ciliata, we confine the attention to the genus of ANATES. In this manner may the whole objects of the universe be grouped, and arranged into kingdoms, classes, orders, genera, and species.

Such a classification and arrangement is called NATURAL HISTORY; and must be considered as the only foundation of any extensive knowledge of nature. To the natural historian, therefore, the world is a collection of existences, the subject of descriptive arrangement. His aim is threefold.

1. To observe with care, and to describe with accuracy, the various objects of the universe.
2. To determine and enumerate all the great classes of objects; to distribute and arrange them into all their subordinate classes, through all degrees of subordination, till he arrive at what are only accidental varieties, which are susceptible of no farther distribution; and to mark with precision the principles of this distribution and arrangement, and the characteristics of the various assemblages.
3. To determine with certainty the particular group to which any proposed INDIVIDUAL belongs.

DESCRIPTION therefore, ARRANGEMENT, and REFERENCE, constitute the whole of his employment; and in this consists all his science.

Did the universe continue unchanged, this would constitute the whole of our knowledge of nature: but we are witnesses of an uninterrupted succession of changes, and our attention is continually called to the EVENTS which are incessantly happening around us. These form a set of objects vastly more interesting to us than the former; being the sources of almost all the pleasures or pains we receive from external objects.

We are therefore much interested in the study of the events which happen around us, and strongly incited to prosecute it: but they are so numerous and so multiform, that the study would be immense, without some contrivance for abbreviating and facilitating the task. The same help offers itself here as in the study of what may be called *quiescent nature*. Events, like existences, are susceptible of classification, in consequence of resemblances and distinction; and

by attention to these, we can acquire a very extensive acquaintance with active nature. Our attention must be chiefly directed to those circumstances in which many events resemble each other, while they differ perhaps in a thousand others. Then we must attend to their most general distinctions; then to distinctions of smaller extent, and so on.

It is in this way accordingly that we have advanced in our knowledge of active nature, and are gradually, and by no means slowly forming assemblages of events more and more extensive, and distributing these with greater and greater precision into their different classes.

In the zealous and attentive prosecution of this task a very remarkable, and interesting observation occurs: In describing those circumstances of similarity among events, and particularly in distributing them according to those similitudes, it is impossible for us to overlook that constancy which is observed in the changes of nature in the events which are the objects of our contemplation. Events which have once been observed to accompany each other are observed always to do so. The rising of the sun is always accompanied by the light of day, and his setting by the darkness of night. Sound argument is accompanied by conviction, impulse by motion, kindness by a feeling of gratitude, and the perception of good by desire. The unexpected experience of mankind informs us, that the events of nature go on in certain regular trains; and if sometimes exceptions seem to contradict this general affirmation, more attentive observation never fails to remove the exception. Most of the spontaneous events of nature are very complicated; and it frequently requires great attention and penetration to discover the simple event amidst a croud of unessential circumstances which are at once exhibited to our view. But when we succeed in this discovery, we never fail to acknowledge the perfect uniformity of the event to what has been formerly observed.

31
Constancy
in the
changes of
nature

But this is not all: We firmly believe that this uniformity will still continue; that fire will melt wax, will burn paper, will harden clay, as we have formerly observed it to do; and whenever we have undoubted proof that the circumstance of situation are precisely the same as in some former case, though but once observed, we expect with irresistible and unshaken confidence that the event will also be the same.

32
Universal-
ly expect-
ed.

It is not surely necessary to adduce many proofs of the universality of this law of human thought. The whole language and actions of men are instances of the fact. In all languages there is a mode of construction which is used to express this relation as distinct from all others; and the conversation of the most illiterate never confounds them, except when the conceptions themselves are confounded. The general employment of the active and passive verb is regulated by it. *Turris eversa est a millibus; turris eversa est terre motu*, expresses two relations, and no school-boy will confound them. The distinction therefore is perceived or felt by all who can speak grammatically. Nor is any language without general terms to express this relation, cause—effect—to occasion. Nay, it is a fact in the mind of brutes, who hourly show that they expect the same uses of every subject which they formerly made of it; and without this, animals would be incapable

of subsistence, and man incapable of all improvement. From this alone memory derives all its value; and even the constancy of natural operation would be useless if not matched or adapted to our purposes by this expectation of and confidence in that constancy.

After all the labours of ingenious men to discover the foundation of this irresistible expectation, we must be contented with saying that such is the constitution of the human mind. It is an *universa fact* in human thought; and for any thing that has been yet discovered, it is an *ultima fact*, not included in any other still more general. We shall soon see that this is sufficient for making it the foundation of true human knowledge; all of which must in like manner be reduced to ultimate facts in human thought.

We must consider this undoubted feeling, this persuasion of the constancy of nature, as an *instinctive* anticipation of events similar to those which we have already experienced. The general analogy of nature should have disposed philosophers to acquiesce in this, however unwelcome to their vanity. In no instance of essential consequence to our safety or well-being are we left to the guidance of our boasted reason; God has given us the surer conduct of natural instincts. No case is so important as this: In none do we so much stand in need of a guide which shall be powerful, infallible, and rapid in its decision. Without it we must remain incapable of all instruction from experience, and therefore of all improvement.

Our sensations are undoubtedly feelings of our mind. But all those feelings are accompanied by an instinctive reference of them to something distinct from the feelings themselves. Hence arises our preception of external objects, and our very notions of this externity (pardon the term). In like manner, this anticipation of events, this irresistible connection of the idea of fire with the idea of burning, is also a feeling of the mind: and this feeling is by a law of human nature referred, without reasoning, to something external as its cause; and like our sensation, it is considered as a *sign* of that external something. It is like the conviction of the truth of a mathematical proposition. This is referred by us to something existing in nature, to a necessary and external relation subsisting between the ideas which are the subjects of the proposition. The conviction is the sign or indication of this relation by which it is brought to our view. In precisely the same manner, the irresistible connection of ideas is interpreted as the sensation or sign of a *necessary connection* of external things or events. These are supposed to include something in their nature which renders them inseparable companions. To this bond of connection between external things we give the name of CAUSATION. All our knowledge of this relation of cause and effect, is the knowledge or consciousness of what passes in our own minds during the contemplation of the phenomena of nature. If we adhere to this view of it, and put this branch of knowledge on the same footing with those called the *abstract sciences*, considering only the *relations* of ideas, we shall acquire *demonstrative science*. If we take any other view of the matter, we shall be led into inextricable mazes of uncertainty and error.

33
Our know-
ledge of
causation,

We see then that the natural procedure of our faculty of abstraction and arrangement, in order to ac-
quire

View of Bacon's Philosophy

quire a more speedy and comprehensive knowledge of natural events, presents them to our view in another form. We not only see them a *fact* in events, but as events naturally and necessarily *connected*. And the expression of *resemblance* among events is also an expression of *connection*; and the arrangement of events in consequence of their resemblance is in fact the *discovery* of those accommodations. The trains of natural appearance being considered as the appointments of the Author of Nature, has occasioned them to be considered also as consequences of *laws* imposed on his works by their great author, and every thing is said to be regulated by fixed laws. But this is the language of analogy. When a sovereign determines on certain trains of conduct for his subjects, he issues his orders. These orders are laws. He enforces the obedience of them by his authority: and thus a certain regularity and constancy of conduct is produced. But should a stranger, ignorant of the promulgation of these laws, and of the exerted authority of the magistrate, observe this uniformity of conduct, he would ascribe it to the genius and disposition of the people; and his observation would be as useful to him for directing the tenor of his own conduct, as the knowledge of the subject himself of the real source of this constancy is for directing his.

34 Laws of nature explained.

Just so in nature, while the theologian professes from his discoveries concerning the existence and superintendance of God, to know that the constant accompaniment of events is the consequence of laws which the great Author and Governor of the universe has imposed on his works, and the ordinary philosopher, a stranger to this scene, and to the unsearchable operations of the SUPREME MIND, must ascribe this constancy to the nature of the things. There is a great resemblance between the expression *natural law* and *grammatical rule*. Rule in strict language implies a command; but in grammar it expresses merely a generality of *fact*, whether of flexion or construction. In like manner, a LAW OF NATURE is to the philosopher nothing but the expression of a generality of fact. A natural or physical law is a generally observed fact; and whenever we treat any subject as a generally observed fact, we treat it physically. It is a physical law of the understanding that argument is accompanied by conviction; it is a physical law of the affection that distress is accompanied by pity; it is a physical law of the material world that impulse is accompanied by motion.

And thus we see that the arrangement of events, or the discovery of those general points of resemblance, is in fact the discovery of the laws of nature; and one of the greatest and most important is, that the laws of nature are constant.

There is no question that this view of the universe is incomparably more interesting and important than that which is taken by the natural historian; contemplating every thing that is of value to us, and, in short, the whole life and movement of the universe. This study, therefore, has been dignified with the name of PHILOSOPHY and of SCIENCE; and natural history has been considered as of importance only in so far as it was conducive to the successful prosecution of philosophy.

35 Object of philosophy.

But the philosopher claims a superiority on another

account: he considers himself as employed in the discovery of causes, saying that philosophy is the study of the objects of the universe, as related by causation, and that it is by the discovery of these relations that he communicates to the world such important knowledge. Philosophy, he says, is the science of causes. The vulgar are contented to consider the prior of two inseparably conjoined events as the cause of the other; the stroke on a bell, for instance, as the cause of sound. But it has been clearly shown by the philosopher that between the blow on the bell and the sensation of sound there are interposed a long train of events. The blow sets the bell a trembling; this agitates the air in contact with the bell; this agitates the air immediately beyond it; and thus he wins the bell and the ear may be interposed a numberless series of events, and as many more between the first impression on the ear and that last impression on the nerve by which the mind is affected. He can no longer therefore follow the nomenclature of the vulgar. Which of the events of this train therefore is the cause of the sensation? None of them: It is that *something* which inseparably connects any two of them, and constitutes their bond of union. These bonds of union or causes he considers as residing in one or both of the connected objects; diversities in this respect must therefore constitute the most important distinctions between them. They are therefore with great propriety called the *qualities*, the *properties*, of these respective subjects.

View of Bacon's Philosophy

52 Called gravitation.

As the events from which we infer the existence of these qualities of things resemble in many respects such events as are the consequences of the exertion of our own powers, these qualities are frequently denominated POWERS, forces, energies. Thus, in the instance just now given of the sound of a bell, we infer the powers of impulse, elasticity, nervous irritability, and animal sensibility.

In consequence of this inference of a necessary connection between the objects around us, we not only infer the posterior event from the prior, or, in common language, the effect from the cause, but we also infer the prior from the posterior, the cause from the effect. We not only expect that the presence of a magnet will be followed by certain motions in iron filings, but when we observe such motions, we infer the presence and agency of a magnet. Joy is inferred from merriment, poison from death, fire from smoke, and impulse from motion. And thus the appearances of the universe are the indications of the powers of the objects in it. Appearances are the language of nature, informing us of their causes. And as all our knowledge of the sentiments of others is derived from our confidence in their veracity; so all our knowledge of nature is derived from our confidence in the constancy of natural operations. A veracity and credibility necessarily resulting from that law of our mental construction by which we are capable of speech, conduct us in the one case; and the constancy of nature, and the principle of induction, by which we infer general laws from particular facts, conduct us in the other. As human sentiment is inferred from language, and the existence of external things from sensation; so are the laws of nature, and the powers of

37 Inferred from effects.

View of
Facon's
Philosophy

View of

of natural objects inferred from the phenomena. It is by the successful study of this language of nature that we derive useful knowledge. The knowledge of the influence of motives on the mind of man enables the statesman to govern kingdoms, and the knowledge of the powers of magnetism enables the mariner to pilot a ship through the pathless ocean.

* Ancient
Metaphy-
sics.

38
Discoveries
of Aristotle
and New-
ton com-
pared.

Such are the lofty pretensions of philosophy. It is to be wished that they be well founded; for we may be persuaded that a mistake in this particular will be fatal to the advancement of knowledge. An author of great reputation* gives us an opportunity of deciding this question in the way of experiment. He says that the ancients were philosophers, employed in the discovery of causes, and that the moderns are only natural historians, contenting themselves with observing the laws of nature, but paying no attention to the causes of things. If he speaks of their *professed* aim, we apprehend that the assertion is pretty just in general. With very few exceptions indeed it may be affirmed of his favourite Aristotle, the philosopher *κατ' ἐξοχην*, and of Sir Isaac Newton. We select these two instances, both because they are set in continual opposition by this author, and because it will be allowed that they were the most eminent students of nature (for we must not yet call them philosophers) in ancient and modern times. Aristotle's professed aim, in his most celebrated writings, is the investigation of causes; and in the opinion of this author, he has been so successful that he has hardly left any employment for his successors beside that of commenting upon his works. We must on the other hand acknowledge that Newton makes no such pretensions, at least in that work which has immortalised his name, and that his professed aim is merely to investigate the *general* laws of the planetary motions, and to apply these to the explanation of particular phenomena. Nor will we say that he has left no employment for succeeding inquirers; but, on the contrary, confess that he has only begun the study, has discovered but one law, and has enabled us to explain only the phenomena comprehended in it alone. But he has not been unsuccessful; his investigation has been complete; and he has discovered beyond all possibility of contradiction a *fact* which is observed through the whole extent of the solar system; namely, that every body, nay that every particle in it, is continually DEFLECTED toward every other body; and that this deflection is, in every instance, proportional to the quantity of matter in that body toward which the deflection is directed, and to the reciprocal of the square of the distance from it. He has therefore discovered a physical law of immense extent. Nor has he been less successful in the explanation of particular phenomena. Of this there cannot be given a better instance than the explanation of the lunar motions from the theory of gravity begun by Newton "Mathesi sua faciem præferente;" and now brought to such a degree of perfection, that if the moon's place be computed from it for any moment within the period of two thousand years back, it will not be found to differ from the place on which she was actually observed by one hundredth part of her own breadth.

We may now desire the champions of the science of causes to name any one cause which has really been discovered by their great matter, whether in the operations of mind or of body. But they must not on this occasion adduce the investigation of any natural law in which he has sometimes succeeded. With still greater confidence may we challenge them to produce any remarkable instance of the explanation of natural phenomena either of mind or body. By explanation, we mean an account of the production, and an appreciation of all the circumstances, susceptible of a scrupulous comparison with fact, and perfectly consistent with it. It is here that the weakness of this philosopher's pretensions is most conspicuous; and his followers candidly acknowledge, that in the enquiries which proceed by experiment, we have not derived great assistance from Aristotle's philosophy. But this, say they, does not derogate from the pre-eminence of his philosophy, because he has shown that the *particular* fields of observation are to be cultivated only by means of experiment. But surely every field of *observation* is particular. There is no *abstract* object of philosophical research, the study of which shall terminate in the philosophy of universals. In every kind of inquiry, that cause alone must be supposed to act which we understand so far as to be able to appreciate its effects in particular circumstances, and compare them with fact, and see their perfect coincidence. If we have discovered causes, they are *known* as far as they are discovered. Their genuine effects are known, and therefore the phenomena which result from their agency are understood. When therefore it is acknowledged, as it must be acknowledged, that mankind have made but little advances in the knowledge of nature, notwithstanding the pretended discovery of causes by Aristotle, and the conducting clue of his philosophy, till of late years; and when it is also allowed that *now*, while we are every day making great additions to this subordinate knowledge, the causes which Aristotle has discovered are forgotten, and his philosophy is neglected; there is great room for suspecting (to say the least), that either the causes which philosophy pretends to have discovered are not real, or that Aristotle and his followers have not aimed at the discovery of causes, but only at the discovery of natural laws, and have failed in the attempt.

There seems here to be a previous question: *Is it possible to discover a philosophical cause*, that something which is neither the prior nor the posterior of the two immediately adjoining events, but their bond of union, and this distinct from the union itself? It is evident that this is an enquiry purely experimental. It is of *human knowledge* we speak. This must depend on the nature of the human mind. This is a matter of contingency, known to us only by experiment and observation. By observing all the feelings and operations of the mind, and classing and arranging them like any other object of science, we discover the general laws of human thought and human reasoning; and this is

all the knowledge we can ever acquire of it, or of any thing else.

Much has been written on this subject. The most acute observation and sound judgment have been employed in the study; and we may venture to say, that considerable progress has been made in pneumatology. Many laws of human thought have been observed, and very distinctly marked; and philosophers are busily employed, some of them with considerable success, in the distribution of them into subordinate classes, so as to know their comparative extent, and to mark their distinguishing characters with a precision similar to what has been attained in botany and other parts of natural history; so that we may hope that this study will advance like others. But in all these researches, no phenomena have occurred which look like the perception or contemplation of these separate objects of thought, these philosophical causes, this power in abstracto. No philosopher has ever pretended to state such an object of the mind's observation, or attempted to group them into classes.

40
In the e-
vents,

We may say at once, without entering into any detail, that those causes, those bonds of necessary union between the naturally conjoined events or objects, are not only perceived *by means* of the events alone, but are perceived solely *in* the events, and cannot be distinguished from the conjunctions themselves. They are neither the objects of separate observation, nor the productions of memory, nor inferences drawn from reflection on the laws by which the operations of our own minds are regulated; nor can they be derived from other perceptions in the way of argumentative inference. We cannot infer the paroxysm of terror from the appearance of impending destruction, nor the fall of a stone when not supported, as we infer the incommensurability of the diagonal and side of a square. This last is *implied* in the very conception or notion of a square; not as a consequence of its other properties, but as one of its essential attributes; and the contrary proposition is not only false, but incapable of being distinctly conceived. This is not the case with the other phenomenon, or any matter of fact. The proofs which are brought of a mathematical proposition, are not the reason of its being true, but the steps by which this truth is brought into our view; and frequently, as in the instance now given, this truth is perceived, not directly, but consequentially, by the inconceivableness of the contrary proposition.

41
Mr Hume's
theory a
petitio
Principii.

Mr Hume derives this irresistible expectation of events from the known effect of custom, the association of ideas. The correlated event is brought into the mind by this well known power of custom, with that vivacity of conception which constitutes belief or expectation. But without insisting on the utility of his theory of belief, it is sufficient to observe, that this explanation begs the very thing to be proved, when it ascribes to custom a *power* of any kind. It is the origin of this very power which is the subject in dispute. Besides, on the genuine principles of scepticism, this custom involves an acknowledgment of past events, of a something different from present impressions, which, in this doctrine (if doctrine it can be called), are the only certain existences in nature: and, lastly, it is known that *our* clear experience is a sufficient foundation for this unshaken confidence and

anticipation. General custom can never, on Mr Hume's principles, give superior vivacity to any particular idea.

This certain nonentity of it as a separate object of observation, and this impossibility to derive this notion of necessary and causal connection between the events of the universe from any source, have induced two of the most acute philosophers of Europe, Mr Leibnitz and Father Malebranche, to deny that there is any such connection, and to assert that the events of the universe go on in corresponding trains, but without any causal connection, just as a well-regulated clock will keep time with the motions of the heavens without any kind of dependence on them. This harmony of events was pre-established by the Author of the Universe, in subserviency to the purposes he had in view in its formation.

All those purposes which are cognizable by us, may certainly be accomplished by this perfect adjustment. But without insisting on the fantastic wildness of this ingenious whim, it is quite enough to observe, that it also is a begging of the question, because it supposes causation when it ascribes all to the agency of the Deity.

Thus we have searched every quarter, without being able to find a source from which to derive this perception of a necessary connection among the events of the universe, or of this confident expectation of the continuance of physical laws; and yet we are certain of the feeling, and of the persuasion, be its origin what it may: for we speak intelligibly on this subject; we speak familiarly of cause, effect, power, energy, necessary connection, motives and their influence, argument and conviction, reasons and persuasion, allurements and emotions, of gravity, magnetism, irritability, &c.; and we carry on conversations on these subjects with much entertainment and seeming instruction. Language is the expression of thought, and every word expresses some notion or conception of the mind; therefore it must be allowed, that we have such notions as are expressed by cause, power, energy. But it is here, as in many cases, we perceive a distinction without being able to express it by a definition; and that we do perceive the relation of causation as distinct from all others, and in particular as distinct from the relation of contiguity in time and place; or the relation of agent, action, and patient, must be concluded from the uniformity of language, which never confounds them except on purpose, and when it is perceived. But even here we shall find, that none of the terms used for expressing those powers of substance which are conceived as the causes of their characteristic phenomena, really express any thing different from the phenomena themselves. Let any person try to define the terms gravity, elasticity, sensibility, and the like, and he will find that the definition is nothing but a description of the phenomenon itself. The words are all derivatives, most of them verbal derivatives, implying action, gravitation, &c. As the general resemblances in shape, colour, &c. are expressed by the natural historian by generic terms, so the general resemblances in event are expressed by the philosopher in generic propositions, which, in the progress of cultivation, are also abbreviated into generic terms.

This abundantly explains the consistency of our language on this subject, both with itself and with the

respecting
causal con-
nection.

View of Bacon's Philosophy

43
The perception of this connection a first principle.

the operations of nature, without however affording any argument for the truth of the assumption, that causes are the objects of philosophic research as separate existences; or that this supposed necessary connection is a *necessary truth*, whether supreme or subordinate. But since the perception of it has its foundation in the constitution of the human mind, it seems intitled to the name of a *first principle*. We are hardly allowed to doubt of this, when we consider the importance of it, and the care of nature to secure us in all things essential to our safety and well-being, from all danger, from inattention, ignorance, or indolence, by an instinct infallible in its information, and instantaneous in its decisions. "It would not be like her usual care (says Hume), if this operation of the mind, by which we infer like effects from like causes, and *vice versa*, were entrusted to the fallacious deduction of our reason, which is slow in its operations, appears not in any degree during the first years of infancy, and in every age and period of human life is extremely liable to error. It is more conformable to her *ordinary caution* (mark the acknowledgment) to secure so necessary an act of the mind by some instinct, or blind tendency, which may be infallible and rapid in all its operations, may discover itself at the first appearance of life, and may be independent of all the laboured deductions of reason. As she has taught us the use of our limbs, without giving us any knowledge of the nerves and muscles by which they are actuated; so she has implanted in us an instinct, which carries forward the thought in a course conformable to that established among external objects, though we be ignorant of the powers and forces on which this regularity depends."

Such a knowledge is quite unnecessary, and therefore causes are no more cognoscible by our intellectual powers than colours by a man born blind: nay, whoever will be at the pains to consider this matter agreeably to the received rules and maxims of logic, will find that necessary connection, or the bond of causation, can no more be the subject of philosophical discussion by man, than the ultimate nature of truth. It is precisely the same absurdity or incongruity, as to propose to examine light with a microscope. Other rational creatures may perceive them as easily as we hear sounds. All that we can say is, that their existence is probable, but by no means certain. Nay, it may be (and we may never know it) that we are not the efficient causes of our own actions, which may be effected by the Deity or by ministering spirits; and this may even be true in the material world. But all this is indifferent to the real occupation of the philosopher, and does not affect either the certainty, the extent, or the utility of the knowledge which he may acquire.

We are now able to appreciate the high pretensions of the philosopher, and his claim to scientific superiority. We now see that this can neither be founded on any scientific superiority of his object, nor of his employment. His object is not causes; and his discoveries are nothing but the discovery of general facts, the discovery of physical laws: and his employment is the same with that of the descriptive historian. He observes and describes with care and accuracy the events of nature; and then he groups them into classes, in consequence of resembling circumstances, detected

44
The object of the philosopher the discovery of physical laws.

in the midst of many others, which are dissimilar and occasional. By gradually throwing out more circumstances of resemblance, he renders his classes more extensive; and, by carefully marking those circumstances in which the resemblance is observed, he characterises all the different classes; and, by a comparison of these with each other, in respect to the number of resembling circumstances, he distributes his classes according to their generality and subordination; thus exhausting the whole assemblage, and leaving nothing unarranged but accidental varieties. In this procedure it is to be remarked, that every grouping of similar events is, *ipso facto*, discovering a general fact, a physical law; and the expression of this assemblage is the expression of the physical law. And as every observation of this constancy of fact affords an opportunity for exerting the instinctive inference of natural connection between the related subjects, every such observation is the discovery of a power, property, or quality, of natural substance. And from what has been said, this observation of event is all we know of the connection, all we know of the natural power. And when the philosopher proceeds farther to the arrangement of events, according to their various degrees of complication, he is, *ipso facto*, making an arrangement of all natural powers according to their various degrees of subordinate influence. And thus his occupation is perfectly similar to that of the descriptive historian, classification and arrangement; and this constitutes all the science attainable by both.

PHILOSOPHY may therefore be defined, the study of the phenomena of the universe, with a view to discover the general laws which indicate the powers of natural substances, to explain subordinate phenomena, and to improve art: Or, in compliance with that natural instinct so much spoken of, Philosophy is the study of the phenomena of the universe, with a view to discover their causes, to explain subordinate phenomena, and to improve art.

The task is undoubtedly difficult, and will exercise our noblest powers. The employment is mainly in itself, and the result of it important. It therefore justly merits the appellation of *philosophy*, although its objects are nowise different from what occupies the attention of other men.

The employment of the philosopher, like that of the natural historian, is threefold; DESCRIPTION, ARRANGEMENT, and REFERENCE; while the objects are not *things* but *events*.

The description when employed about events, may be more properly termed *history*. A philosophical history of nature consists in a complete or copious enumeration and narration of facts, properly selected, cleared of all unnecessary or extraneous circumstances, and accurately narrated. This constitutes the materials of philosophy. We cannot give a better example of this branch of philosophical occupation than astronomy.

From the beginning of the Alexandrian school to this day, astronomers have been at immense pains in observing the heavenly bodies, in order to detect their true motions. This has been a work of prodigious difficulty: for the appearances are such as might have been exhibited although the real motions had been extremely different. Not that our senses give

View of Bacon's Philosophy

Philosophy defined.

46
The employment of the philosopher.

View of
Bacon's
Philosophy

us false information; but we form hastily, and frequently false judgments, from these informations; and call those things deceptions of sense, which are in fact errors of judgment. But the true motions have at last been discovered, and have been described with such accuracy, that the history may be considered as nearly complete. This is to be found in the usual systems of astronomy, where the tables contain a most accurate and synoptical account of the motion; so that we can tell with precision in what point of the heavens a planet has been seen at any instant that can be named.

47
Phenomenology.

Sir Isaac Newton's Optics is such another perfect model of philosophical history, as far as it goes. This part of philosophy may be called PHENOMENOLOGY.

Having in this manner obtained the materials of philosophical description, we must put them into a compendious and perspicuous form, so that a general knowledge of the universe may be easily acquired and firmly retained. This is to be done by classification and arrangement, and this classification must proceed on resemblances observed in the events; and the subsequent arrangement must be regulated by the distinctions of which those resemblances are still susceptible. This assemblage of events into groups must be expressed. They are facts; therefore the expression must be propositions. These propositions must be what the logicians call *general or abstract propositions*; for they express, not any individual fact of the assemblage, but that circumstance in which they all resemble. Such propositions are the following: Proof is accompanied by belief; kindness is accompanied by gratitude; impulse is accompanied by motion. These are usually called *general facts*; but there are none such; every fact is individual. This language, however inaccurate, is very safe from miscontruction, and we may use it without scruple. These propositions are NATURAL OR PHYSICAL LAWS; and then the detecting and marking those resemblances in event, is the investigation of physical laws and we may denominate this employment of the philosopher INVESTIGATION.

48
Investigation.

In the prosecution of this task, it will be found that the similarities of fact are of various extent; and thus we shall form physical laws of various extent; and we shall also find that some are subordinate to others; for the resemblance of a number of facts in one circumstance does not hinder a part of them from also resembling in another circumstance: and thus we shall find subordinations of fact in the same way as of inessential qualities. And it is found here, as in natural history, that our assemblage of resembling events will be the more extensive as the number of resembling circumstances is smaller; and thus we shall have kingdoms, classes, orders, genera, and species of phenomena, which are expressed by physical laws of all those different ranks.

It has been already observed, that this observation of physical laws is always accompanied by a reference of that uniformity of event to a natural bond of union between the concomitant facts which is conceived by us as the *cause* of this concomitancy; and therefore this procedure of the philosopher is considered as the discovery of those causes, that is the discovery of those powers of natural substances which

constitute their physical relations, and may justly be called their distinguishing *qualis* or *properties*. This view of the matter gives rise to a new nomenclature and language. We give to those powers generic names, such as *sensibility, intelligence, irritability, gravity, elasticity, fluidity, magnetism, &c.* These terms without exception, mark resembling circumstances of event; and no other definition can be given of them but a description of these circumstances. In a few cases which have been the subjects of more painful or refined discussion, we have proceeded farther in this abbreviation of language.

We have framed the verb "to gravitate," and the verbal noun "gravitation," which purely expresses the fact, the phenomenon; but is conceived to express the *operation* or energy of the cause or natural power. It is of importance to keep in mind this metaphysical remark on these terms; for a want of attention to the pure meaning of the words has frequently occasioned very great mistakes in philosophical science.

We may with propriety call this part of the philosopher's employment **ARTIOLOGY**.

We shall give an instance of its most successful application to the class of events already adduced as an example of philosophic history or phenomenology.

Kepler, a celebrated Prussian astronomer, having maturely considered the phenomena recorded in the tables and observations of his predecessors, discovered, amidst all the varieties of the planetary motions, three circumstances of resemblance, which are now known by the name of *Kepler's laws*.

View of
Bacon's
Philosophy49
Artiology.50
Kepler's
laws an in-
stance.

1. All the planets describe ellipses, having the sun in one focus.
2. The elliptic areas described by a planet in the different parts of its orbit, are proportional to the times of description.
3. The squares of the periodic times are proportional to the cubes of the mean distances from the sun.

By this observation or discovery, the study of the planetary motions was greatly promoted, and the calculation of their appearances was now made with a facility and an accuracy which surpassed all hopes: for the calculation of the place of a planet at any proposed instant was reduced to the geometrical problem of cutting off an area from an ellipse of known dimensions, which should bear the same proportion to the whole area, as the time for whose duration the motion is required, has to the known time of a complete revolution.

Long after this discovery of Kepler, Sir Isaac Newton found that these laws of Kepler were only particular cases of a fact or law still more general. He found that the deflections of the planets from uniform rectilinear motion were all directed to the sun; and that the simultaneous deflections were inversely proportional to the squares of the distances from him.

This was established a physical law of vast extent; but further observation showed him that the motion of every body of the solar system was compounded of an original motion of projection, combined with a deflection towards every other body; and that the simultaneous deflections were proportional to the quantity of matter in the body towards which they were directed,

hended un-
der one
more gene-
ral law.

View of
Bacon's
Philosophy

View of
Bacon's
Philosophy

directed, and to the reciprocal of the square of the distance from it. Thus was the law made still more general. He did not stop here. He compared the deflection of the moon in her orbit with the simultaneous deflection of a stone thrown from the hand, and describing a parabola; and he found that they followed the same law, that is, that the deflection of the moon in a second, was to that of the stone in the same time, as the square of the stone's distance from the centre of the earth, to the square of the moon's distance from it. Hence he concluded, that the deflection of a stone from a straight line was just a particular instance of the deflections which took place through the whole solar system.

and which has given rise to an axiom, "that a body cannot act at a distance, or where it is not;" and thus have thought themselves obliged to look out for an immediate and contiguous agent in all these phenomena.

But the philosophers who profess to be most scrupulous in their adherence to the rules of philosophic discussion, deny the legitimacy of this pretended investigation of causes, saying that this doctrine is in direct opposition to the procedure of the mind in acquiring the knowledge of causes. Since the fact of impulse is not readily observed in the celestial deflections, nor in the motions of heavy bodies, the law cannot be inferred. They say that it is not even necessary to show that the phenomena of the celestial motion are unlike the phenomena of impulse, although this can be done in the completest manner. It is enough that neither the fluid nor the impulse are observed; and therefore they are in the right when they assert, that is inherent in, or accompanies all the bodies of the system, a power by which they deflect to one another. (See OPTICS, n^o 66, 67.)

54
While impulse itself is never observed.

52
called gravitation.

The deflection of a stone is one of the indications it gives of its being *gravis* or heavy; whence he calls it *gravitation*. He therefore expresses the physical law which obtains through the whole solar system, by saying that "every body *gravitates* to every other body; and the gravitations are proportional to the quantity of matter in that other body, and inversely proportional to the square of the distance from it."

Thus we see how the arrangement of the celestial phenomena terminated in the discovery of physical laws; and that the expression of this arrangement is the law itself.

The debate is foreign to our present purpose, which is only to show how the observation and arrangement of phenomena terminates in the discovery of their causes, or the discovery of the powers or properties of natural substances.

This is a task of great difficulty, as it is of great importance. There are two chief causes of this difficulty.

Since the fall of a heavy body is one instance of the physical law, and since this fall is considered by all as the effect of its *weight*, and this weight is considered as the cause of the fall, the same cause is assigned for all the deflections observed in the solar system; and all the matter in it is found to be under the influence of this cause, or to be heavy; and thus his doctrine has been denominated the *system of universal gravitation*.

1. In most of the spontaneous phenomena of nature there is a complication of many events, and some of them escape our observation. Attending only to the most obvious or remarkable, we conjoin these only in our imagination, and are apt to think these the concomitant events in nature, the proper indication of the cause, and the subjects of this philosophical relation, and to suppose that they are always conjoined by nature. Thus it was thought that there resided in a vibrating chord a power by which the sensation of sound was excited, or that a chord had a sounding quality. But late observations have shown clearly that there is an inconceivable number of events interposed between the vibration of the chord and the sensitive affection of our ear; and therefore, that sound is not the effect of the vibration of the chord, but of the very last event of this series; and this is completely demonstrated by showing that the vibration and the sound are *not necessarily connected*, because they are not *always* connected, but require the interposition of air or of some other elastic body.

55
Causes of the difficulty of philosophical investigation.

53
Attempts to include this law under impulse.

Philosophers have gone farther, and have supposed that gravity is a power, property, or quality, residing in all the bodies of the solar system. Sir Isaac Newton does not expressly say so, at least in that work where he gives an account of these discoveries. He contents himself with the immediate consequence of the first axiom in natural philosophy, viz. that every body remains in a state of rest, or of uniform rectilinear motion, unless affected by some moving force. Since the bodies of the solar system are neither in a state of rest, nor of uniform rectilinear motion, they must be considered as so affected; that is, that there operates on every one of them a moving force, directed towards all the others, and having the proportions observed in the deflection.

These observations show the necessity of the most accurate and minute observation of the phenomena, that none of those intermediate events may escape us, and we be thus exposed to the chance of imaginary connections between events which are really far asunder in the procedure of nature. As the study has improved, mistakes of this kind have been corrected; and philosophers are careful to make their trains of events under one name as short as possible. Thus, in medicine, a drug is no longer considered as a *specific* remedy for the disease which is sometimes cured when it has been used, but is denominated by its most immediate operation on the animal frame: it is no longer called a *febrifuge*, but a *febrific*.

Other philosophers have endeavoured to show, that this general fact, detected by Sir Isaac Newton, is included in another still more general, viz. that every body moves which is impelled by another body in motion. They assert, that all the bodies of the solar system are continually impelled by a fluid which they call *ether*, which is moving in all places, and in all directions, or in circular vortices, and hurries along with it the planets and all heavy bodies. It would seem that the familiarity of motion produced by impulse, at least in those instances in which our own exertions are most employed, has induced philosophers to adopt such notions; perhaps, too, they are influenced by an obscure and indistinct notion affixed to the term action, as applied to changes in the material world,

Bacon's
Philosophy56
Means of
insuring
success.

2. When any natural powers combine their influence in a spontaneous phenomenon of nature, it is frequently very difficult to discover what part of the complicated effect is the effect of each; and to state those circumstances of similarity which are the foundation of a physical law, or intitle us to infer the agency of any natural power. The most likely method for insuring success in such cases is to get rid of this complication of event, by putting the subject into such a situation that the operation of all the known powers of nature shall be suspended, or so modified as we may perfectly understand *their effects*. We can thus appreciate the effects of such as we could neither modify nor suspend, or we can discover the existence of a new law, the operation of a new power.

This is called *making an experiment*; and is, of all, the most effectual way of advancing in the knowledge of nature, and has been called EXPERIMENTAL PHILOSOPHY.

It seems, however, at first sight, in direct opposition to the procedure of nature in forming general laws. These are formed by induction from multitudes of individual facts, and must be affirmed to no greater extent than the induction on which they are founded. Yet it is a matter of fact, a physical law of human thought, that one simple, clear, and unequivocal experiment, gives us the most complete confidence in the truth of a general conclusion from it to every similar case. Whence this anomaly? It is not an anomaly or contradiction of the general maxim of philosophical investigation, but the most refined application of it. There is no law more general than this, that "Nature is constant in all her operations." The judicious and simple form of our experiment insures us (we imagine) in the complete knowledge of all the circumstances of the event. Upon this supposition, and this alone, we consider the experiment as the faithful representative of every possible case of the conjunction. This will be more minutely considered afterwards.

The last branch of philosophic occupation is the explanation of subordinate phenomena. This is nothing more than the referring any particular phenomenon to that class in which it is included; or, in the language of philosophy, it is the pointing out the general law, or that general fact of which the phenomenon is a particular instance. Thus the feeling of the obligations of virtue is thought to be explained, when it is shown to be a particular case of that regard which every person has for his dearest interests. The rise of water in pumps is explained, when we show it to be a particular case of the pressure of fluids, or of the air. The general law under which we show it to be properly arranged is called the PRINCIPLE of the explanation, and the explanation itself is called the THEORY of the phenomenon. Thus Euler's explanation of the lunar irregularities is called a theory of the lunar motions on the principle of gravitation.

This may be done either in order to advance our own knowledge of nature, or to communicate it to others. If done with the first view, we must examine the phenomenon minutely, and endeavour to detect every circumstance in it, and thus discover all the known laws of nature which concur in its production; we then appreciate the operation of each according to the circumstances of its exertion; we then combine all these, and compare the result with the pheno-

menon. If they are similar, we have explained the phenomenon. We cannot give a better example than Franklin's explanation of the phenomena of thunder and lightning. See LIGHTNING, and ELECTRICITY Index.

If we explain a phenomenon from known principles, we proceed synthetically from the general law already established and *known* to exert its influence in the present instance. We state this influence both in kind and degree according to the circumstances of the case; and having combined them, we compare the result with the phenomenon, and show their agreement, and thus it is explained. Thus, because all the bodies of the solar system mutually gravitate, the moon gravitates to the sun as well as to the earth, and is continually, and in a certain determinate manner, deflected from that path which she would describe did she gravitate only to the earth. Her motion round the earth will be retarded during the first and third quarters of her orbit, and accelerated during the second and fourth. Her orbit and her period will be increased during our winter, and diminished during our summer. Her apogee will advance, and her nodes will recede; and the inclination of her orbit will be greatest when the nodes are in syzygie, and least when they are in quadrature. And all these variations will be in certain precise degrees. Then we show that all these things actually obtain in the lunar motions, and they are considered as explained.

This summary account of the object and employment in all philosophical discussion is sufficient for pointing out its place in the circle of the sciences, and will serve to direct us to the proper methods of prosecuting it with success. Events are its object; and they are considered as connected with each other by causation, which may therefore be called the philosophical relation of things. The following may be adopted as the fundamental proposition on which all philosophical discussion proceeds, and under which every philosophical discussion or discovery may be arranged:

"Every change that we observe in the state or condition of things is CONSIDERED BY US as an effect, indicating the agency, characterising the kind, and determining the degree of its INFERRED CAUSE."

As thus enounced, this proposition is evidently a physical law of human thought. It may be enounced as a necessary and independent truth, by saying, *every change in the state and condition of things IS AN EFFECT*, &c. And accordingly it has been so enounced by Dr Reid*; and its title to this denomination has been abundantly supported by him. But we have no occasion to consider it as possessing this quality. We are speaking of philosophy, which is something contingent, depending on the existence and constitution of an intellectual being such as man; and, in conformity to the view which we have endeavoured to give of human knowledge in the subjects of philosophical relation, it is quite sufficient for our purpose that we maintain its title to the rank of an universal law of human thought. This will make it a first principle, even although it may not be a necessary truth.

All the proof necessary for this purpose is universality of fact; and we believe this to be without exception. We are not to expect that all mankind have made

or will ever make, a formal declaration of their opinion; but we may venture to say that all have made it, and continually do make it, virtually. What have the philosophers of all ages been employed about but the discovery of the causes of those changes that are incessantly going on? *Nil turpius physico* (says Cicero) *quam fieri sine causâ quidquam dicere.* Human curiosity has been directed to nothing so powerfully and so constantly as to this. Many absurd causes have been assigned for the phenomena of the universe; but no set of men have ever said that they happened without a cause. This is so repugnant to all our propensities and instincts, that even the atheistical sect, who, of all others, would have profited most by the doctrine, have never thought of advancing it. To avoid so shocking an absurdity, they have rather allowed that chance, that the concurrence of atoms, are the causes of the beautiful arrangements of nature. The thoughtless vulgar are no less solicitous than the philosophers to discover the cause of things; and the poet expresses the natural and instinctive passion of all men, when he says,

Felix qui potuit rerum cognoscere causas.

And this anxiety is not to nourish, but to get rid of superstitious fears: for thus

— *metus omnes, et inexorabile fatum*
Subjicit pedibus, strepitumque Acherontis avari.

Had men never speculated, their conduct alone gives sufficient evidence of the universality of the opinion. The whole conduct of man is regulated by it, nay almost wholly proceeds upon it, in the most important matters, and where experience seems to leave us in doubt; and to act otherwise, as if any thing whatever happened without a cause, would be a declaration of insanity. Dr Reid has beautifully illustrated this truth, by observing, that even a child will laugh at you if you try to persuade him that the top, which he misses from the place where he left it, was taken away by nobody. You may persuade him that it was taken away by a fairy or a spirit; but he believes no more about this nobody, than the master of the house when he is told that nobody was the author of any piece of theft or mischief. What opinion would be formed, says Dr Reid, of the intellects of the jurymen, on a trial for murder by persons unknown, who should say that the fractured skull, the watch and money gone, and other like circumstances, might possibly have no cause? he would be pronounced insane or corrupted.

60
Contro-
verted by
Mr Hume

We believe that Mr Hume is the first author who has ventured to call the truth of this opinion in question; and even he does it only in the way of mere possibility. He acknowledges the generality of the opinion; and he only objects to the foundation of this generality: and he objects to it merely because it does not quadrate with his theory of belief; and therefore it may happen that some men may have no such opinion. But it must be observed on this occasion, that the opinion of a philosopher is of no greater weight in a case like this than that of a ploughboy. If it be a first principle, directing the opinions and actions of all, it must operate on the minds of all. The philosopher is the only person who may chance to be without it; for it requires much labour, and long habits reso-

lutely maintained, to warp our natural sentiments; and experience shows us that they may be warped if we are at sufficient pains. It is also worthy of remark, that this philosopher seems as much under the influence of this law as ordinary mortals. It is only when he is aware of its not tallying with his other doctrines that his scruples appear. Observe how he speaks when off his guard: "As to those impressions which arise from the senses, their ultimate cause is, in my opinion, perfectly inexplicable by human reason; and it will always be impossible to decide with certainty whether they arise immediately from the object, are produced by the creative power of the mind, or are derived from the Author of our being."

Among these alternatives he never thought of their not being derived from any cause.

But it is not enough to show that this is a physical law of the human mind: we have assumed it as a first principle, the foundation of a whole science; therefore not included in or derived from any thing more general. Mr Hume's endeavours to show that it is not a necessary truth, show with sufficient evidence that most attempts to derive it in the way of argument are *petitiones principii*; a thing very commonly met with in all attempts to prove first principles. It cannot be proved by induction of facts that every event has a cause, because induction always supposes an *observed fact* or event.) Now in by far the greatest number of events the causes are unknown. Perhaps in no event whatever do we know the real cause, or that power or energy which, without any intervention, produces the effect. No man can say, that in the simplest event which he ever observed, he was fully apprised of every circumstance which concurred to its production. We suppose that no event in nature can be adduced more simple than the motion of a suspended glass ball when gently struck by another glass ball; and we imagine that most of our readers will say that he perfectly sees every thing which happens in this phenomenon. We believe, too, that most of our readers are of opinion that a body is never put in motion but by the impulse of another, except in the cases of animal motion; and that they are disposed to imagine that magnets put iron in motion, and that an electrified body moves another by means of an interposed though invisible fluid somehow circulating round them. Now we must inform such readers, that unless the stroke has been very smart, so smart indeed as to shatter the glass balls, the motion of the suspended ball was produced without impulse: that is, the two balls were not in contact during the stroke; and the distance between them was not less than the 9000th part of an inch, and probably much greater. We must say farther, that it is not certain that even the most violent stroke, such as would shatter them to pieces, is enough to bring them into real contact. The proofs of this singular position are too long for this place; but the evidence will be sufficiently seen by consulting the article OPTICS, n^o 66, 67.

Unless, therefore, our readers are willing to allow that the suspended ball was put in motion by a repulsive force inherent in one or both balls, they must acknowledge that they do not fully know all the circumstances of this so simple phenomenon, or all the train of events which happen in it; and therefore they are reduced to the necessity of *supposing*, although they do

View of
Bacon's
Philosophy

not far it, an intervening fluid or matter, by the immediate action of whose *assisting* particles the motion is produced.

This being the case in the simplest phenomenon that we can pitch upon, what shall we say of the numberless multitudes which are incomparably more complex? Must we not acknowledge that the efficient causes, even in the vulgar sense of the word, the immediately preceding events, are unknown, because the conjunctions are not observed? and therefore it cannot be said that it is from experimental induction that this truth gains universal belief. Experience, so far from supporting it as a direct proof, forms rather the strongest argument against it; for we have no experiment of unquestionable authority but the narrow circle of our own power exerted on our thoughts and actions. And even here there are perhaps cases of change where we cannot say with certainty that we perceive the efficient cause.

Nothing seems to remain, therefore, but to allow that this physical law of human judgment is instinctive, a constituent of the human soul, a first principle; and incapable of any other proof than the appeal to the feelings of every man.

63

Causes not
observed
but inferred
from the phenomena
which are
the language
of nature.

Simply to say, that every change is considered as an effect, is not giving the whole characters of this physical law. The cause is not always, perhaps never *observed*, but is *inferred* from the phenomena. The inference is therefore in every instance dependant on the phenomenon. The phenomenon is to us the language of nature: It is therefore the sole indication of the cause and of its agency: It is therefore the indication of the very cause, and of no other. The observed change therefore characterises the cause, and marks its kind. This is confirmed by every word of philosophical language, where, as has already been observed, the names of the inferred powers of nature are nothing but either abbreviated descriptions of the phenomena, or terms which are defined solely by such descriptions. In like manner, the phenomenon determines the cause in a *particular degree*, and in no other; and we have no immediate measure of the degree of the cause but the phenomenon itself. We take many measures of the cause, it is true; but on examination they will be found not to be immediate measures of the cause, but of the effect. Assuming gravitation as the cause of the planetary deviations from uniform rectilinear motion, we say that the gravitation of the moon is but $\frac{1}{171825}$ th part of the gravitation of a stone thrown from the hand: but we say this only from observing that the deflection of the stone is 3600 times greater than the simultaneous deflection of the moon. In short, our whole knowledge of the cause is not only *founded* on our knowledge of the phenomenon, but *it is the same*. This will be found a remark of immense consequence in the prosecution of philosophical researches; and a strict attention to it will not only guard us against a thousand mistakes into which the reasoning pride of man would continually lead us, but will also enable us fully to detect many egregious and fatal blunders made in consequence of this philosophical vanity. Nothing can be more evident than that whenever we are puzzled, it would be folly to continue groping among those obscure beings called *causes*, when we have their prototypes, the phenomena themselves, in our hands.

Such is the account which may be given of philosophy, the study of the works of God, as related by causation. It is of vast extent, reaching from an atom to the glorious Author of the Universe, and comprehending the whole connected chain of intelligent, sensitive, and inanimate beings. The philosopher makes use of the descriptions and arrangements of the natural historian as of mighty use to himself in the beginning of his career; confiding in the uniformity of nature, and expecting that similarity in the quiescent properties of things will be accompanied by some resemblances in those more important properties which constitute their mutual dependences, linking them together in a great and endlessly ramified chain of events.

We have endeavoured to ascertain with precision the peculiar province of philosophy, both by means of its object and its mode of procedure. After this it will not require many words to point out the methods for prosecuting the study with expedition and with success. The rules of philosophizing, which Newton premises to his account of the planetary motions, which he so scrupulously followed, and with a success which gives them great authority, are all in strict conformity to the view we have now given of the subject.

The chief rule is, that similar causes are to be assigned to similar phenomena. This is indeed the source of all our knowledge of connected nature; and without it the universe would only present to us an incomprehensible chaos. It is by no means, however, necessary to enjoin this as a maxim for our procedure: it is an instinctive propensity of the human mind. It is absolutely necessary, on the contrary, to caution us in the application of this propensity. We must be extremely confident in the certainty of the resemblance before we venture to make any inference. We are prone to reason from analogy: the very employment is agreeable; and we are ever disposed to embrace opportunities of engaging in it. For this reason we are satisfied with very slight resemblances, and eagerly run over the consequences, as if the resemblances were complete; and our researches frequently terminate in falsehood.

This propensity to analogical reasoning is aided by another equally strong, and equally useful, when properly directed; we mean the propensity to form general laws: it is in fact a propensity to discover *causes*, which is equivalent to the establishing of general laws. It appears in another form, and is called a love of order or taste for simplicity; and this is encouraged or justified as agreeable to the uniformity and simplicity of nature. "Natura semper sibi similis et consona," says Newton; "Frustra fit per plura, quod fieri potest per pauciora," says another. The beautiful, the wise economy of nature, are phrases in every body's mouth; and Newton enjoins us to adopt no more causes than are sufficient to explain the phenomena. All this is very well, and is true in its own degree; but it is too frequently the subterfuge of human vanity and self-love. This inordinate admiration of the economy and simplicity of nature is generally conjoined with a manifest love of system, and with the actual production of some new system, where from one general principle some extensive theory or explanation is deduced and offered to the world. The author sees a sort of resemblance

blance between a certain series of phenomena and the consequences of some principle; and thinks the principle adequate to their explanation. Then, on the authority of the acknowledged simplicity of nature, he roundly excludes all other principles of explanation; because, says he, this principle is sufficient "et frustra fit per plura," &c. We could point out many instances of this kind in the writings of perhaps the first mathematician and the poorest philosopher of this century; where extensive theories are thus cavalierly exhibited, which a few years examination have shown to be nothing but analogies, indistinctly observed, and what is worse, inaccurately applied.

To regulate these hazardous propensities, and keep philosophers in the right path, Newton inculcates another rule, or rather gives a modification of this injunction of simplicity. He enjoins, that no cause shall be admitted but what is real. His words are, that *no causes shall be admitted but such as are true, and sufficient to account for the phenomena.* We apprehend that the meaning of this rule has been mistaken by many philosophers, who imagine that by *true* he means causes which really exist in nature, and are not mere creatures of the imagination. We have met with some who would boggle at the doctrines of Aristotle respecting the planetary motions, *viz.* that they are carried along by conducting intelligent minds, because we know of *none such* in the universe; and who would nevertheless think the doctrine of the Cartesian vortices deserving of at least an examination, because we see such vortices exist, and produce effects which have some resemblance to the planetary motions, and have justly rejected them *solely* because this resemblance has been very imperfect. We apprehend Newton's meaning by these words is, that no cause of any event shall be admitted, or even considered, which we *do not know* to be actually concurring or exerting some influence *in that very event.* If this be his meaning, he would reject the Cartesian vortices, and the conducting spirits of Aristotle for one and the same reason; not because they were not adequate to the explanation, nor because such causes did not exist in nature, but because we did not *see them* anyhow concerned in the phenomenon under consideration. We neither see a spirit nor a vortex, and therefore need not trouble ourselves with enquiring what effects they would produce. Now we know that this was his very conduct, and what has distinguished him from all philosophers who preceded him, though many by following his example, have also been rewarded by similar success. This has procured to Newton the character of the *most* philosopher; and modest his procedure may, for distinction's sake, be called, because the contrary procedure of others did not originate so much from ignorance as from vanity. Newton's conductor in this was not modesty, but sagacity, prudence, caution, and to say it purely, it was sound judgment.

For the bonds of nature, the supposed philosophical causes are not *observed*: they are *inferred* from the phenomena. When two substances are observed, and only when they are observed, to be connected in any series of events, we *infer* that they are connected by a natural power: but when one of the substances is not seen, but fancied, no law of human thought produces any inference whatever. For this reason alone New-

ton stopped short at the last fact which he could discover in the solar system, that all bodies were directed to all other bodies according to certain regular laws of distance and quantity of matter. When he had done nothing in philosophy, that he had discovered no cause, and that to merit any praise he should show how this deflection was produced;—that is, that he knew no more than he had told them; that he saw nothing causing this deflection; and was contented with having described it so exactly, that a good mathematician could now make tables of the planetary motions as accurate as he pleased, and with hoping in a few years to have every purpose of navigation and of philosophical curiosity completely answered; and he was not disappointed. And when philosophers on all sides were contriving hypothetical fluids and vortices, which would produce these deflections, he contented himself with showing the total inconsistency of these explanations with the mechanical principles acknowledged by their authors; showing that they had transgressed both parts of his rule, their causes neither being real nor sufficient for explaining the phenomena. A cause is sufficient for explaining a phenomenon only when its legitimate consequences are perfectly agreeable to these phenomena.

Newton's discoveries remain without any diminution or change: no philosopher has yet advanced a step further.

But let not the authority, or even the success of Newton be our guide. Is his rule founded in reason? It surely is. For if philosophy be only the interpretation of nature's language, the inference of causes from the phenomena, a fancied or hypothetical phenomenon can produce nothing but a fanciful cause, and can make no addition to our knowledge of real nature.

All hypotheses therefore must be banished from philosophical discussion as frivolous and useless, administering to vanity alone. As the explanation of any appearance is nothing but the pointing out the general fact of which this is a particular instance, a hypothesis can give no explanation: knowing nothing of cause and effect but the conjunction of two events, we see nothing of causation where one of the events is hypothetical. Although all the legitimate consequences of a hypothetical principle should be perfectly similar to the phenomenon, it is extremely dangerous to assume this principle as the real cause. It is illogical to make use of the economy of nature as an argument for the truth of any hypothesis; for if true, it is a physical truth, a matter of fact, and true only to the extent in which it was observed, and we are not intitled to say that it is so one step further; therefore not in this case *till it be observed.* But the proposition that nature is so economical is false; and it is astonishing that it has been so lazily acquiesced in by the *masters* of hypotheses; for it is not the *authors* who are deceived by it, they are generally led by their own vanity. Nothing is more observable than the prodigious variety of nature. That the same phenomena may be produced by different means is well known to the astronomers, who must all grant, that the appearances of motion will be precisely the same whether the earth moves round the sun like the other planets, or whether the sun with his attendant planets moves round the earth: and that

60
This doctrine founded in reason.

67
Danger of hypotheses.

65
A true cause explained.

the demonstration of the first opinion is had from a fact totally unconnected with all the deflections or even with their causes: for it may be asserted, that Dr Bradley's discovery of the aberration of the fixed stars, in consequence of the progressive motion of light, was the first thing which put the Copernican system beyond question; and even this is still capable of being explained in another way. The Author of Nature seems to delight in variety; and there cannot be named a single purpose in which the most inconceivable fertility in resources is not observed. It is the most delightful occupation of the curious mind and the sensible heart to contemplate the various contrivances of nature in accomplishing similar ends.

As a principle therefore on which to found any maxim of philosophical procedure, this is not only injudicious, because imprudent and *left* to mislead, but as false, and almost sure to mislead. In conformity to this observation, it must be added, that nothing has done so much harm in philosophy as the introduction of hypothesis.

Authors have commonly been satisfied with very slight resemblances, and readers are easily misled by the appearances of reasoning which these resemblances have countenanced. The ancients, and above all Aristotle, were much given to this mode of explanation, and have filled philosophy with absurdities. The slightest resemblances were with them sufficient foundations of theories. It has been by very slow degrees that men have learned caution in this respect; and we are sorry to say that we are not yet cured of the disease of hypothetical systematizing, and to see attempts made by ingenious men to bring the frivolous theories of antiquity again into credit. Nay, modern philosophers even of the greatest name are by no means exempted from the reproach of hypothetical theories. Their writings abound in ethers, nervous fluids, animal spirits, vortices, vibrations, and other invisible agents. We may affirm that all these attempts may be shown to be either unintelligible, fruitless, or false. Either the hypothesis has been such that no consequence can be distinctly drawn from it, on account of its obscurity and total want of resemblance to any thing we know; or the just and legitimate consequences of the hypothesis are inconsistent with the phenomena (*s*). This is remarkably the case in the hypotheses which have been introduced for the explanation of the mechanical

phenomena of the universe. These can be examined by accurate science, and the consequences compared without any mistake; and nothing else but a perfect agreement should induce us even to listen to any hypothesis whatever.

It may here be asked, Whether, in the case of the most perfect agreement, after the most extensive comparison, the hypothesis should be admitted? We believe that this must be left to the feelings of the mind. When the belief is irresistible, we can reason no more. But as there is no impossibility of as perfect an agreement with some other hypothesis, it is evident that it does not convey an irrefragable title to our hypothesis. It is said, that such an agreement authorizes the reception of the hypothetical theory in the same manner as we *must* admit that to be the *true* cypher of a letter which will make perfect sense of it. But this is not true: in decyphering a letter we know the sounds which *must* be represented by the characters, and that they are really the constituents of speech: but in hypothetical explanations the first principle is not known to exist; nay, it is possible to make two cyphers, each of which shall give a meaning to the letter. Instances of this are to be seen in treatises on the art of decyphering; and there has been lately discovered a national character (the *egan* discovered in Ireland) which has this property.

We conclude our criticism on hypothetical explanations with this observation, that it is *impossible* that they can give any addition of knowledge. In every hypothesis we thrust in an intermediate event between the phenomenon and some general law; and this event is not seen, but *supposed*. Therefore, according to the true maxims of philosophical investigation, we give no explanation; for we are not by this means enabled to assign the general law in which this particular phenomenon is included: nay, the hypothesis makes no addition to our list of general laws; for our hypotheses must be *proved*, in order to tally with all the phenomena. The hypothesis therefore is understood only *by* and *in* the phenomena; and it must not be made more general than the phenomena themselves. The hypothesis gives no generalisation of facts. Its very application is founded on a great coincidence of facts; and the hypothetical fact is thrust in between two which we really observe to be united by nature. The applicability therefore of the hypothesis is not more extensive

(*s*) It has often been matter of amusement to us to examine the hypothetical theories of ingenious men, and to observe the power of nature even when we are transgressing her commands, *Naturam expellat furca, tamen nigra recertitur*. The hypothesis of an ingenious man is framed in perfect conformity to nature's dictates: for you will find that the hypothetical cause is touched and retouched, like the first setting of a picture, till it is made to resemble the phenomena, and the cause is still inferred, nay explained, in spite of all his ingenuity, from the phenomenon; and then, instead of desiring the spectators to pay him his due praise, by saying that the picture is like the man, he insists that they shall say, what gives him no credit, that the man is like the picture. But, alas! this is seldom the case: The picture is generally an anamorphosis, unlike any thing extant in nature, and having parts totally incongruous. We have seen such pictures, where a wood is standing on the sea, and an eye is on the end of an elephant's trunk: and yet when this was viewed through a proper glass, the wood became an eyebrow to the eye, and the proboscis was a very pretty ringlet of hair. We beg indulgence for this piece of levity, because it is a most opposite illustration of a hypothetical theory. The resemblance between the principle and phenomenon is true only in detached unconnected scraps, and the principle itself is an incongruous patchwork. But by a perversion of the rules of logic, all these incongruities are put out of view, and the explanation is something like the phenomenon.

View of Bacon's Philosophy

View of Bacon's Philosophy

extensive than the similarity of facts which we observe, and the hypothetical law is not more general than the observed law. Let us then throw away entirely the hypothetical law, and insist the observed one in our list of general laws: it will be in different language from the hypothetical law, but it will express the same facts in nature.

discover the perhaps long train of intermediate operations, and also see in what manner and degree the real principle of explanation concurs in the ostensible process of nature.

68 On what occasions they may be useful

It is in experimental philosophy alone that hypotheses can have any just claim to admission; and here they are not admitted as explanations, but as conjectures serving to direct our line of experiments.

In all such cases it is evident that our investigation (and investigation it most strictly is) must proceed by steps, conducted by the sure hand of logical method. To take an instance from the material world, let us listen to Galileo while he is teaching his friends the cause of the rise of water in a pump. He says that it is owing to the pressure of the air. This is his principle; and he announces it in all its extent. All matter, says he, is heavy, and in particular air is heavy. He then points out the connection of this general principle with the phenomenon.

Effects only appear; and by their appearance, and the previous information of experience, causes are immediately ascertained by the perfect similarity of the whole train of events to other trains formerly observed: Or they are suggested by more imperfect resemblances of the phenomena; and the suggestions are made with stronger or fainter evidence, according as the resemblance is more or less perfect. These suggestions do not amount to a confidential inference, and only raise a conjecture. Wishing to verify or overturn this conjecture, we have recourse to experiment; and we put the subject under consideration in such a situation, that we can say what will be the effect of the conjectural cause if real. If this tallies with the appearance, our conjecture has more probability of truth, and we vary the situation, which will produce a new set of effects of the conjectured cause, and so on. It is evident that the probability of our conjecture will increase with the increase of the conformity of the legitimate effects of the supposed cause with the phenomena, and that it will be entirely destroyed by *one* disagreement. In this way conjectures have their great use, and are the ordinary means by which experimental philosophy is improved. But conjectural systems are worse than nonsense, filling the mind with false notions of nature, and generally leading us into a course of improper conduct when they become principles of action. This is acknowledged even by the abettors of hypothetical systems themselves, when employed in overturning those of their predecessors, and establishing their own: witness the successive maintainers of the many hypothetical systems in medicine, which have had their short-lived course within these two last centuries.

Air being heavy, it must be supported: it must lie and press on what supports it: it must press on the surface AB of the water in the cistern surrounding the pipe CD of the pump; and also on the water C within this pipe. He then takes notice of another general principle which exerts its subordinate influence in this process. Water is a fluid; a fluid is a body whose parts yield to the smallest impression; and, by yielding, are easily moved among themselves: and no little parcel of the fluid can remain at rest unless it be equally pressed in every direction, but will recede from that side where it sustains the greatest pressure. In consequence of this fluidity, known to be a property of water, if any part of it is pressed, the pressure is propagated thro' the whole; and if not resisted on every side, the water will move to that side where the propagated pressure is not resisted. All these subordinate or collateral propositions are supposed to be previously demonstrated or allowed. Water therefore must yield to the pressure of the air unless pressed by it on every side, and must move to that side where it is not withheld by some opposite pressure. He then

proceeds to show, from the structure of the pump, that there is no opposing pressure on the water in the inside of the pump. "F r (says he) suppose the piston thrust down till it touches the surface of the water in the pipe; suppose the piston now drawn up by a power sufficient to lift it, and all the air incumbent on it, and suppose it drawn up a foot or a fathom—there remains nothing now (says he) that I know of, to press on the surface of the water. In short (says he), gentlemen, it appears to me, that the water in the pump is in the same situation that it would be in were there no air at all, but water poured into the cistern to a height AF; such that the column of water FABG presses

69 True mode of philosophical procedure,

After these observations, it cannot require much discussion to mark the mode of procedure which will insure progress in all philosophical investigations.

The sphere of our intuitive knowledge is very limited; and we must be indebted for the greatest part of our intellectual attainments to our rational powers, and it must be deductive. In the spontaneous phenomena of nature, whether of mind or body, it seldom happens that the energy of that natural power, which is the principle of explanation, is so immediately connected with the phenomenon that we see the connection at once. Its exertions are frequently concealed, and in all cases modified, by the joint exertions of other natural powers: the particular exertion of each must be considered apart, and their mutual connection traced out. It is only in this way that we can

View of
Bacon's
Philosophy

presses on the surface AB as much as the air does. Now in this case we know that the water at C is pressed upwards with a force equal to the weight of a column of water, having the section of the pipe for its base and CH for its height. The water below C therefore will be pressed up into the pipe CD, and will rise to G, so that it is on a level with the external water FG; that is, it will rise to H. This is a necessary consequence of the weight and pressure of the incumbent column FABG, and the fluidity of the water in the cistern. Consequences perfectly similar must necessarily follow from the weight and pressure of the air; and therefore on drawing up the piston from the surface C of the water, with which it was in contact, the water must follow it till it attain that height which will make its own weight a balance for the pressure of the circumambient air. Accordingly, gentlemen, the Italian plumbers inform me, that a pump will not raise water quite fifty palms; and from their information I conclude, that a pillar of water fifty palms high is somewhat heavier than a pillar of air of the same base, and reaching to the top of the atmosphere."

70
The syn-
thetic me-
thod.

Thus is the phenomenon explained. The rise of the water in the pump is shown to be a particular case of the general fact in hydrostatics, that fluids in communicating vessels will stand at heights which are inversely as their densities, or that columns of equal weights are in equilibrio.

This way of proceeding is called arguing *a priori* the synthetic method. It is founded on just principles; and the great progress which we have made in the mathematical sciences by this mode of reasoning shows to what length it may be carried with irresistible evidence. It has long been considered as the only inlet to true knowledge; and nothing was allowed to be known with certainty which could not be demonstrated in this way to be true. Accordingly logic or the art of reasoning, which was also called the art of discovering truth, was nothing but a set of rules for successfully conducting this mode of argument.

Under the direction of this infallible guide, it is not surely unreasonable to expect that philosophy has made sure progress towards perfection; and as we know that the brightest geniuses of Athens and of Rome were for ages solely occupied in philosophical researches in every path of human knowledge, it is equally reasonable to suppose that the progress has not only been sure but great. We have seen that the explanation of an appearance in nature is nothing but the arrangement of it into that general class in which it is comprehended. The class has its distinguishing mark, which when it is found in the phenomenon under consideration, fixes it in its class, there to remain for ever an addition to our stock of knowledge. Nothing can be lost any other way but by forgetting it; and the doctrines of philosophers must be stable like the laws of nature.

We have seen, however, that the very reverse of all this is the case; that philosophy has but very lately emerged from worse than total darkness and ignorance; that what passed under the name of philosophy was nothing but a system of errors (if systems they could be called), which were termed doctrines, delivered with the most imposing apparatus of logical demonstration, but belied in almost every instance by experience, and

affording us no assistance in the application of the powers of nature to the purposes of life. Nor will this excite much wonder in the mind of the enlightened reader of the present day, who reflects on the use that in this dialectic process was made of the *categories*, and the method in which these categories were formed. From first principles so vague in themselves, and so gratuitously assumed, ingenious men might deduce many different conclusions all equally erroneous: and that this was actually done, no surer evidence can be given, than that hardly a lifetime elapsed in which the whole system of doctrines which had captivated the minds of the most penetrating, have not been oftener than once exploded and overturned by another system, which flourished for a while, and then was supplanted by a third which shared the same fate. Hence was an infallible proof of their error, for instability is incompatible with truth.

It is allowed by all that this has been the case in those branches of study at least which contemplate the philosophical relations of the material world, in astronomy, in mechanical philosophy, in chemistry, in physiology, in medicine, in agriculture. It is also acknowledged, that in the course of less than two centuries back we have acquired much knowledge on these very subjects, call it philosophy, or by what name you will, so much more conformable to the natural course of things, that the deductions made from it by the same rules of the synthetic method are more conformable to fact, and therefore better fitted to direct our conduct and improve our powers. It is also certain that these bodies of doctrine which go by the name of philosophical systems, have much more stability than in ancient times; and though sometimes in part superseded, are seldom or never wholly exploded.

This cannot perhaps be affirmed with equal confidence with respect to those speculations which have our intellect or propensities for their object: and we have not perhaps attained such a representation of human nature as will bear comparison with the original: nor will the legitimate deductions from such doctrines be of much more service to us for directing our conduct than those of ancient times; and while we observe this difference between these two general classes of speculations, we may remark, that it is conjoined with a difference in the manner of conducting the study. We have proceeded in the old Aristotelian method when investigating the nature of mind; but we see the material philosophers running about, passing much of their time away from books, in the shop of the artisan, or in the open fields engaged in observation, labouring with their hands, and busy with experiments. But the speculation on the intellect and the active powers of the human soul seems unwilling to be indebted to any thing but his own ingenuity, and his labours are confined to the closet. In the first class, we have met with something like success, and we have improved many arts: in the other, it is to be feared that we are not much wiser, or better, or happier, for all our philosophical attainments.

Here, therefore, must surely have been some great, some fatal mistake. There has indeed been a material defect in our mode of procedure, in the employment of this method of reasoning as an inlet to truth. The

No inlet to
truth,

fact

View of
Bacon's
Philosophy

fact is, that philofophers have totally miftaken the road of difcovery, and have pretended to fet out in their inveftigation in the very point where this journey fhould have terminated.

The Ariftotelian logic, the fyllogiftic art, that art fo much boasted of as the only inlet to true knowledge, the only means of difcovery, is in direft oppofition to the ordinary procedure of nature, by which we every day, and in every action of our lives, acquire knowledge and difcover truth. It is not the art of difcovering truth, it is the art of communicating knowledge, and of detecting error: it is nothing more than the application of this maxim, "whatever is true of a whole clafs of objects, is true of each individual of that clafs." This is not a juft account of the art of difcovering truth, nor is it a complete account of the art of reafoning. Reafoning is the producing belief; and whatever mode of argumentation invariably and irrefiftibly produces belief, is reafoning. The ancient logic fupposes that all the firft principles are already known, and that nothing is wanted but the application of them to particular facts. But were this true, the application of them, as we have already obferved, can hardly be called a difcovery: but it is not true; and the fact is, that the firft principles are generally the chief objects of our reſearch, and that they have come into view only now and then as it were by accident, and never by the labour of the logician. He indeed can tell us whether we have been miftaken; for if our general principle be true, it muſt influence every particular caſe. If, therefore, it be falſe in any one of theſe, it is not a true principle. And it is here that we difcover the ſource of that fluctuation which is fo much complained of in philoſophy. The authors of ſyſtems give a ſet of consecutive propoſitions logically deduced from a firſt principle, which has been haſtily adopted, and has no foundation in nature. This does not hinder the amuſement of framing a ſyſtem from it, nor this ſyſtem from pleaſing by its ſymmetry; and it takes a run: but when ſome officious, follower thinks of making ſome uſe of it, which requires the compariſon with experience and obſervation, they are found totally unlike, and the whole fabric muſt be abandoned as unfound: and thus the ſucceſſive ſyſtems were continually puſhing out their predeceſſors, and preſently met with the ſame treatment.

How was this to be remedied? The ratiocination was ſeldom egregiouſly wrong; the fyllogiftic art and ere now attained a degree of perfection which left little room for improvement, and was ſo familiarly underſtood by the philoſophical practitioners, that they ſeldom committed any great blunders. Muſt we examine the firſt principles? This was a taſk quite new in ſcience; and there were hardly any rules in the received ſyſtems of logic to direct us to the ſucceſſful performance of it. Ariftotle, the ſagacious inventor of thoſe rules, had not totally omitted it; but in the fervor of philoſophic ſpeculation he had made little uſe of them. His fertile genius never was at a loſs for firſt principles, which answered the purpoſe of verbal diſquiſition without much riſk of being belied on account of its diſſimilitude to nature; for there was frequently no prototype with which his ſyſtematic doctrine could be compared. His enthuſiaſtic followers

found abundant amuſement in following his example; and philoſophy, no longer in the hands of men acquainted with the world, converſant in the great book of nature, was now confined almoſt entirely to reſolute monks equally ignorant of men and of things. But curioſity was awakened, and the men of genius were fretted as well as diſgusted with the diſquiſitions of the ſchools, which one moment raiſed expectations, by the ſymmetry of compoſition, and the next moment blaſted them by their inconſiſtency with experience.

They ſaw that the beſt way was to begin *de novo*, to throw away the firſt principles altogether, without exception or examination, and endeavour to find out new ones which ſhould ſtand the teſt of logic; that is, ſhould in every caſe be agreeable to fact.

Philoſophers began to reflect, that under the unnoticed tuition of kind nature we have acquired much uſeful knowledge. It is therefore highly probable, that her method is the moſt proper for acquiring knowledge, and that by imitating her manner we ſhall have the like ſucceſs. We are too apt to flight the occupations of children, whom we may obſerve continually buſy turning every thing over and over, putting them into every ſituation, and at every diſtance. We excuſe it, ſaying that it is an innocent amuſement; but we ſhould ſay with an ingenious philoſopher (Dr Reid), that they are moſt ſeriouſly and rationally employed: they are acquiring the habits of obſervation; and by merely indulging an undetermined curioſity, they are making themſelves acquainted with ſurrounding objects: they are ſtruck by ſimilitudes, and amuſed with mere claſſification. If ſome new effect occurs from any of their little plays, they are eager to repeat it. When a child has for the firſt time tumbled a ſpoon from the table, and is pleaſed with its jingling noiſe on the floor, if another lies within its reach, it is ſure to ſhare the ſame fate. If the child is indulged in this diverſion, it will repeat it with a greedineſs that deſerves our attention. The very firſt eager repetition ſhows a confidence in the conſtancy of natural operations, which we can hardly aſcribe wholly to experience; and its keenneſs to repeat the experiment, ſhows the intereſt which it takes in the exerciſe of this moſt uſeful propenſity. It is beginning the ſtudy of nature; and its occupation is the ſame with that of a Newton computing the motions of the moon by his ſublime theory, and comparing his calculus with obſervation. The child and the philoſopher are equally employed in the contemplation of a ſimilarity of event, and are anxious that this ſimilarity ſhall return. The child, it is true, thinks not of this abſtract object of contemplation, but throws down the ſpoon again to have the pleaſure of hearing it jingle. The philoſopher ſuſpects that the conjunction of events is the conſequence of a general law of nature, and tries an experiment where this conjunction recurs. The child is happy, and eager to enjoy a pleaſure which to us appears highly frivolous; but it has the ſame foundation with the pleaſure of the philoſopher, who rejoices in the ſucceſs of his experiment: and the fact, formerly a triſtle to both, now acquires importance. Both go on repeating the experiment, till the fact ceases to be a novelty to either: the child is ſatisfied,

and the philosopher has now established a new law of nature.

Such (says this amiable philosopher) is the education of kind nature, who from the beginning to the end of our lives makes the play of her scholars their most instructive lessons, and has implanted in our mind the curiosity and the inductive propensity by which we are enabled and disposed to learn them. The exercise of this inductive principle, by which nature prompts us to infer general laws from the observation of particular facts, gives us a species of logic new in the schools, but old as human nature. It is certainly a method of discovery; for by these means general principles, formerly unknown, have come into view.

74
Is a just
logic.

It is a just and rational logic; for it is founded on, and indeed is only the habitual application of, this maxim, "That whatever is true with respect to every individual of a class of events, is true of the whole class." This is just the inverse of the maxim on which the Aristotelian logic wholly proceeds, and is of equal authority in the court of reason. Indeed the expression of the general law is only the abbreviated expression of every particular instance.

This new logic, therefore, or the logic of induction, must not be considered as subordinate to the old, or founded on it. See *Logic*, Part III. chap. 5. In fact, the use and legitimacy of the Aristotelian logic is founded on the inductive,

All animals are mortal;

All men are animals: therefore

All men are mortal.

This is no argument to any person who chooses to deny the mortality of man: even although he acknowledges his animal nature, he will deny the major proposition.

It is beside our purpose to show, how a point so general, so congenial to man, and so familiar, remained so long unnoticed, although the disquisition is curious and satisfactory. It was not till within these two centuries that the increasing demand for practical knowledge, particularly in the arts, made inquisitive men see how useless and insufficient was the learning of the schools in a y road of investigation which was connected with life and business; and observe, that society had received useful information chiefly from persons actually engaged in the arts which the theoreticists were endeavouring to illustrate; and that this knowledge consisted chiefly of experiments and observations, the only contributions which their authors could make to science.

The *Novum Organum* of Bacon, which points out the true method of forming a body of real and useful knowledge, namely, the study of nature in the way of description, observation, and experiment, is undoubtedly the most perfect that science ever received. It may be considered as the grammar of nature's language: it is a new method to the logic of Aristotle; not only in its nature, but in its effect.

75
Is chief
rule.

As the logic of Aristotle had its rules, so has the Baconian or inductive; and this work, the *Novum Organum Scientiarum*, contains them all. The chief rule, and indeed the rule from which all the rest are but derivations, is, that "the induction of particulars must be carried as far as the general affirmation which

is deduced from them." If this be not attended to, the mind of man, which from his earliest years shows great eagerness in searching for first principles, will frequently ascribe to the operation of a general principle events which are merely accidental. Hence the popular belief in omens, palmistry, and all kinds of fortune telling.

View of
Bacon's
Philosophy
76
For disco-
vering ge-
neral prin-
ciples,

This rule must evidently give a new turn to the whole track of philosophical investigation. In order to discover first principles, we must make extensive and accurate observations, so as to have copious inductions of facts, that we may not be deceived as to the extent of the principle inferred from them. We must extend our acquaintance with the phenomena, paying a minute attention to what is going on all around us; and we must study nature, not shut up in our closet drawing the picture from our own fancy, but in the world, copying our lines from her own features.

To delineate human nature, we must see how men act. To give the philosophy of the material world, we must notice its phenomena.

This method of studying nature has been prosecuted during these two last centuries with great eagerness and success. Philosophers have been busy in making accurate observations of facts and copious collections of them. Men of genius have discovered points of resemblance, from which they have been able to infer many general powers both of mind and body; and resemblances, among these have suggested powers still more general.

By these efforts investigation became familiar; philosophers studied the rules of the art, and became more expert; hypotheses were banished, and nothing was admitted as a principle which was not inferred from the most copious induction. Conclusions from such principles became every day more conformable to experience. Mistakes sometimes happened; but recourse being had to more accurate observation or more copious induction, the mistakes were corrected. In the present study of nature, our steps are more slow, and hesitating and painful; our conclusions are more limited and modest, but our discoveries are more certain and progressive, and the results are more applicable to the purposes of life. This pre-eminence of modern philosophy over the ancient is seen in every path of inquiry. It was first remarkable in the study of the material world; and there it still continues to be most conspicuous. But it is no less to be seen in the later performances of philosophers in metaphysics, pneumatology, and ethics, where the mode of investigation by analysis and experiment has been greatly adopted; and we may add, that it is this juster view of the employment which has restored philosophers to the world, to society. They are no longer to be found only in the academies of the sophists and the cloisters of a convent, but in the discharge of public and private duty. A philosophic genius is a genius for observation as well as reflection, and he says, *Homo sum, humani a me nihil alienum puto.*

77
And recti-
fying mis-
takes.

After saying so much on the nature of the employment, and the mode of procedure, it requires no deep penetration to perceive the value of the philosophical character. If there is a propensity in the human mind which

78

sophic cha-
racter.

View of Bacon's Philosophy

which distinguishes us from the inferior orders of sentient beings, without the least circumstance of interference, a propensity which alone may be taken for the characteristic of the species, and of which no trace is to be found in any other, it is disinterested intellectual curiosity, a love of discovery for its own sake, independent of all its advantages.

79 We should think modestly of our rational powers.

We think highly (and with great justice do we think so) of our rational powers; but we may carry this too far, as we do every ground of self-estimation. To every man who enjoys the cheering thought of living under the care of a wise Creator, this boasted prerogative will be viewed with more modesty and diffidence; and he has given us evident marks of the rank in which He esteems the rational powers of man. In no case that is of essential importance, of indispensable necessity, not only to our well-being but to our very existence, has He left man to the care of his reason alone; for in the first instance. He has given us reason

To guide the helm, while passion blows the gale.

80 Importance of our instinctive principles.

God has not trusted either the preservation of the individual or the continuance of the race to man's notions of the importance of the task, but has committed them to the surer guards of hunger and of sexual desire. In like manner, He has not left the improvement of his noblest work, the intellectual powers of the soul of man, to his own notions how important it is to his comfort that he be thoroughly acquainted with the objects around him. No: He has committed this also to the sure hand of curiosity: and he has made this so strong in a few superior souls, whom He has appointed to give light and knowledge to the whole species, as to abstract them from all other pursuits, and to engage them in intellectual research with an ardour which no attainment can ever quench, but, on the contrary, inflames it the more by every draught of knowledge.

————— But what need words
To paint its power? For this the daring youth
Breaks from his weeping mother's fondling arms
In foreign climes to rove. The pensive sage,
Heedless of sleep, or midnight's hurtful vapour,
Hangs o'er the sickly taper.—Hence the scorn
Of all familiar prospects, though beheld
With transport once. Hence th' attentive gaze
Of young astonishment.
Such is the bounteous providence of Heaven,
In every breast implanting the desire
Of objects new and strange, to urge us on
With unremitting labour to attain
The sacred stores that wait the rip'ning soul
In Truth's exhaustless bosom *Liken'd.*

But human life is not a situation of continual necessity; this would ill suit the plans of its Beneficent Author: and it is from induction of phenomena totally opposite to this, and from such induction alone, that we have ever thought of a wise Creator. His wisdom appears only in his beneficence. Human life is a scene filled with enjoyment; and the soul of man is stored with propensities and powers which have pleasure in direct terms, for their object. Another striking

View of Bacon's Philosophy

81 Our disposition to reason

distinction of our nature is a continual disposition to refinement, of which few traces are to be found in the actions of other animals. There is hardly a gift of nature so grateful in itself as to please the feeblest mind of man till he has moulded it to his fancy. Not contented with food, with raiment, and with shelter, he must have nice cookery, ornamental dress, and elegant housing. He hunts when he is not hungry, and he refines sexual appetite into a most elegant passion. In the same manner he has improved the sense as the source of the knowledge of the objects around him, so as to derive from them the means of subsistence and comfort, into the most elegant and pleasing of all gratifications, the accumulation of intellectual knowledge, independent of all consideration of its advantages. And as every man has a title to the enjoyment of such pleasures as he can attain without injuring his neighbour; so it is allowable to such as have got the means of intellectual improvement, without relinquishing the indispensable social duties, to push this advantage as far as it will go; and, in all ages and countries, it has been considered as forming the greatest distinction between men of easy fortune and the poor, who must earn their subsistence by the sweat of their brow. The plebeian must learn to work, the gentleman must learn to think; and nothing can be a surer mark of a groveling soul than for a man of fortune to have an uncultivated mind.

82 Ought to be cherished as far as it is subservient to the duties of life.

Let us then cherish to the utmost this distinguishing propensity of the human soul: but let us do even this like philosophers. Let us cultivate it as it is; as the handmaid to the arts and duties of life; as the guide to something yet more excellent. A character is not to be estimated from what the person knows, but from what he can perform. The accumulation of intellectual knowledge is too apt to create an inordinate appetite for it; and the man habituated to speculation is, like the miser, too apt to place that pleasure in the mere possession, which he ought to look for only or chiefly in the judicious use of his favourite object. Like the miser, too, his habits of hoarding up generally unfit him for the very enjoyment which at setting out he proposed to himself. Seldom do we find the man, who has devoted his life to scientific pursuits for their own sake, possessed of that superiority of mind which the active employ to good purpose in times of perplexity; and much seldomer do we find him possessed of that promptitude of apprehension, and that decision of purpose, which are necessary for passing through the difficult scenes of human life.

But we may use the good things of this life without abusing them; and by moderation here, as in all other pursuits, derive those solid advantages which philosophy is able to bestow. And these advantages are great. To enumerate and describe them would be to write a great volume. We may just take notice of one, which is an obvious consequence of that strict and simple view which we have given of the subject; and this, a modest opinion of our attainments. Appearances are all that we know; causes are for ever hid from our view; the powers of our nature do not lead us so far. Let us therefore, without hesitation, relinquish all pursuits which have such things as ultimate principles for objects of examination. Let us attend to the subordinations of things which it is our great business to

83 Limits of our knowledge.

explore.

View of
Bacon's
Philosophy

explore Among these there is such a subordination as that of means to ends, and of instruments to an operation. All will acknowledge the absurdity of the project of viewing light with a microscope. It is equally absurd for us to examine the nature of knowledge, of truth, of infinite wisdom, by our intellectual powers. We have a wide field of accessible knowledge in the works of God; and one of the greatest advantages, and of the most sublime pleasures, which we can derive from the contemplation, is the view which a judicious philosophic research will most infallibly give us of a world, not consisting of a number of detached objects, connected only by the fleeting tie of co-existence, but an *universe*, a *system* of beings, all connected together by causation, with innumerable degrees of subordination and subserviency, and all cooperating in the production of one great and glorious purpose. The heart which has but a spark of sensibility must be warmed by such a prospect, must be pleased to find itself an important part of this stupendous machine; and cannot but adore the inconprehensible artful who contrived, created, and directed the whole. Let us not listen, then, to the timid admonitions of theological ignorance, which shrinks with superstitious horror from the thoughts of accounting for every thing by the powers of nature, and considers these attempts as an approach to atheism. Philosophical disquisition will, on the contrary, exhibit these general laws of the universe, that wonderful concatenation and adjustment of every thing both material and intellectual, as the most striking instance of incomprehensible wisdom; which, by means so few and so simple, can produce effects, which by their grandeur dazzle our imagination, and by their multiplicity elude

34
Philosophical disquisition gives just notions of God and of our own souls.

all possibility of enumeration. Of all the obstacles which the weakness, the folly, or the sinful vanity of men, have thrown in the way of the theologian, there is none so fatal, so hostile to all his endeavours, as a cold and comfortless system of materialism, which the reasoning pride of man first engendered, which made a figure among a few speculators in the last century, but was soon forgotten by the philosophers really busy with the observation of nature and of nature's God. It has of late reared up its head, being now cherished by all who wish to get rid of the stings of remorse, as the only opinion compatible with the peace of the licentious and the sensual: for we may say to them as Henry IV. said to the prince of Wales, "Thy will was, father Henry, to that thought." In vain will the divine attempt to lay this devil with the metaphysical exorcisms of the school; it is philosophy alone that can detect the cheat. Philosophy singles out the characteristic phenomena which distinguish every substance; and philosophy never will hesitate in saying that there is a set of phenomena which characterize mind and another which characterize body, and that these are *absolutely* different. Continually appealing to facts, to the phenomena, for our knowledge of every cause, we shall have no difficulty in deciding that thought, memory, volition, joy, hope, are not compatible attributes with bulk, weight, elasticity, fluidity. *Tuta subegi Pala*; philosophy will maintain the dignity of human nature, will detect the sophisms of the materialists, confute their arguments; and she alone will restore to the countenance of nature that ineffable beauty of which these would deprive her, who would take away the supreme Mind which shines from within and gives life and expression to every feature.

P H I

Philosophy *Natural Philosophy.* See *Natural Philosophy*, *PHILOSOPHY*, and *PHYSICS*.
Philosophy *Experimental Philosophy.* See *Experimental Philosophy*.
Philosophy *Moral Philosophy.* See *Moral Philosophy*.

PHILOSTORGIUS, an ecclesiastical historian of the 4th century, was born in Cappadocia, and wrote an abridgment of ecclesiastical history, in which he treats Athanasius with some severity. This work contains many curious and interesting particulars. The best edition is that of Henry de Valois in Greek and Latin. There is also attributed to him a book against Porphyry.

PHILOSTRATUS (Flavius), was an ancient Greek author. He wrote the Life of Apollonius Tyranensis, and some other things which have come down to our time. Eusebius against Hierocles calls him an Athenian, because he taught at Athens; but Lamy and Suidas always speak of him as a Lemnian; and he himself, in his life of Apollonius, that he resided to be at Lemnos when he was young. He frequented the schools of the sophists; and he mentions his having heard Damianus of Ephesus, Proclus Nauracianus, and Hippodromus of Leipsa. This seems to prove that he lived in the reign of the emperor Severus, from 193 to 212, when these sophists flourished. He

P H I

became known afterwards to Severus's wife Julia Augusta, and was one of those learned men whom this philosophic empress had continually about her. It was by her command that he wrote the Life of Apollonius Tyranensis, as he relates himself in the same place where he informs us of his connections with that learned lady. Suidas and Helychius say that he was a teacher of rhetoric, first at Athens and then at Rome, from the reign of Severus to that of Philippus, who obtained the empire in 244.

Philostratus's celebrated work is the Life of Apollonius: which has erroneously been attributed to Lucian, because it has been printed with some of that author's pieces. Philostratus endeavours, as Cyril observes, to represent Apollonius as a wonderful and extraordinary person; rather to be admired and adored as a god than to be considered as a mere man. Hence Eunapius, in the preface to his Lives of the Sophists, says that the proper title of that work would have been, *The Coming of a God to Man*; and Hierocles, in his book against the Christians which was called *Philasther*, and which was refuted by Eusebius in a work still extant, among other things drew a comparison between Apollonius and Jesus Christ. It has always been supposed that Philostratus composed his work with a view to discredit the miracles and doctrines of our Lord,

Philostratus.

Philoftra-
tus.

by setting up other miracles and other doctrines against them, and this supposition may be true; but that Apollonius was really an impostor and magician may not be so certain. He may, for what we know, have been a wife and excellent person; and it is remarkable, that Eusebius, though he had the worst opinion of Philostratus's history, says nothing ill of Apollonius. He concluded that that history was written to oppose the history of Jesus; and the use which the ancient infidels made of it justifies his opinion; but he draws no information from it with regard to Apollonius. It would have been improper to have done so; since the sophistical and affected style of Philostratus, the sources from whence he owns his materials to have been drawn, and, above all, the absurdities and contradictions with which he abounds, plainly show his history to be nothing but a collection of fables, either invented or at least embellished by himself.

The works of Philostratus, however, have engaged the attention of critics of the first class. Grævius had intended to have given a correct edition of them, as appears from the preface of Meric Casaubon to a dissertation upon an intended edition of Homer, printed at London in 1658, 8vo. So had Bentley, who designed to add a new Latin version of his notes; and Fabricius says that he saw the first sheet of Bentley's edition printed at Leipzig in 1691. Both these designs were dropped. A very exact and beautiful edition was published at length at Leipzig, 1709, in folio, by Olearius, professor of the Greek and Latin tongues in that university; who has proved himself perfectly qualified for the work he undertook, and shown all the judgment, learning, and industry, that are required in an excellent editor.

At the end of Apollonius's Life there are 95 Letters which go under his name. They are not, however, believed to be his; the style of them being very affected, and like that of a sophist, while they bear in other respects all the marks of a forgery. Philostratus says that he saw a collection of Apollonius's Letters in Hadrian's library at Antium, but had not inserted them all among these. They are short, and have in them little else than moral sentences. The Lives of the Sophists contain many things which are to be met with nowhere else. The Heroics of Philostratus are only a dialogue between a vitner of Thracian Chersonesus and a Phœnician, in which the former draws characters of Homer's heroes, and represents several things differently from that poet; and this upon the faith of Protefilaus's ghost, who had lately visited his farm, which was not far from the tomb of this hero. Olearius conjectures, with much probability, that Philostratus's design in this dialogue was secretly to criticise some things in Homer, which he durst not do openly on account of the great veneration then paid to him, and for fear of the odium which Zoilus and others had incurred by censuring him too freely. The images are elegant descriptions and illustrations of some ancient paintings and other particulars relating to the fine arts: to which Olearius has subjoined the description of some statues by Callistratus; for the same reason that he subjoined Eusebius's book against Hierocles to the Life and Letters of Apollonius, namely, because the subjects of these respective works are related to each other. The last piece is a collection of

Vol. XIV.

Philostratus's Letters; but some of these, though it is not easy to determine which, were written by a nephew to our Philostratus, of the same name, as were also the last eighteen in the book of images. This is the reason why the title runs not *Philostrati*, but *Philostratorum que supersunt annis*.

There were many persons of the name of Philostratus among the ancients; and there were many other works of the Philostratus here recorded, but no others are extant besides those we have mentioned.

PHILOTTIS, a servant maid at Rome, saved her countrymen from destruction. After the siege of Rome by the Gauls, the Fidenates assembled an army, and marched against the capital, demanding all the wives and daughters in the city as the only conditions of peace. This demand astonished the senators; and when they refused to comply, Philottis advised them to send all their female slaves disguised in matron's clothes, and she offered to march herself at the head. Her advice was followed; and when the Fidenates had feasted late in the evening, and were quite intoxicated and fallen asleep, Philottis lighted a torch as a signal for her countrymen to attack the enemy. The whole was successful; the Fidenates were conquered; and the senate, to reward the fidelity of the female slaves, permitted them to appear in the dress of the Roman matrons.

PHILOXENUS, an officer of Alexander, who received Cilicia at the general division of the provinces. — A son of Ptolemy, who was given to Pelopidas as an hostage. — A dythyrambic poet of Cythera. He enjoyed the favour of Dionysius tyrant of Sicily for some time, till he offended him by seducing one of his female singers. During his confinement Philoxenus composed an allegorical poem called *Cyclops*; in which he had delineated the character of the tyrant under the name of Polyphemus, and represented his mistress under the name of Galatœa, and himself under that of Ulysses. The tyrant, who was fond of writing poetry, and of being applauded, removed Philoxenus from his dungeon; but the poet refused to purchase his liberty by saying things unworthy of himself, and applauding the wretched verses of Dionysius, and therefore he was sent to the quarries. Being set at liberty, he some time after was asked his opinion at a feast about some verses which Dionysius had just repeated, and which the courtiers had received with the greatest applause. Philoxenus gave no answer, but he ordered the guards that surrounded the tyrant's table to take him back to the quarries. Dionysius was pleased with his pleasantry and with his firmness, and immediately forgave him. Philoxenus died at Ephesus about 380 years before Christ.

PHILTER, or PHILTRE, (*Philtrum*), in pharmacy, &c. a strainer.

PHILTER, is also used for a drug or preparation, which it is pretended will excite love. — The word is formed from the Greek *φιλο*. "I love," or *φιλος*, "lover."

Philters are distinguished into *true* and *spurious*, and were given by the Greeks and Romans to excite love. (See LOVE in medicine.) The spurious are spells or charms, supposed to have an effect beyond the ordinary laws of nature by some magic virtue; such are those said to be given by old women, witches, &c. — The true

+ G

philters

Philof-
||
Philter

Philyca
Phinchas.

philters are those supposed to work their effect by some natural and magnetical power. There are many grave authors who believe the reality of these philters, and allege matter of fact in confirmation of their sentiments: among the rest, Van Helmont, who says, that upon holding a certain herb in his hand for some time, and taking afterwards a little dog by the foot with the same hand, the dog followed him wherever he went, and quite deserted his former master; which he pretends to account for thus: The heat communicated to the herb, not coming alone, but animated by the emanations of the natural spirits, determines the herb towards the man, and identifies it to him: having then received this ferment, it attracts the spirit of the other object magnetically, and gives it an amorous motion.—But this is mere cant; and all philters, whatever facts may be alleged, are mere chimeras.

PHILYCA, in botany. See PHYLICA.

PHILYRA (fab. hist.), was one of the Oceanides, whom Saturn met in Thrace. The god, to escape from the vigilance of Rhea, changed himself into a horse, to enjoy the company of Philyra, by whom he had a son half a man and half a horse, called *Chiron*. Philyra was so ashamed of giving birth to such a monster, that she entreated the gods to change her nature. She was accordingly metamorphosed into a tree, called by her name among the Greeks.

PHIMOSIS, in medicine, a disorder of the penis, in which the prepuce is so strict or tense, that it cannot be drawn back over the glans. See SURGERY.

PHINEHAS, or, as the Jews pronounce it PHINCHAS, was the son of Eleazar, and grandson of Aaron. He was the third high priest of the Jews, and discharged this office from the year of the world 2571, till towards the year 2590. He is particularly commended in Scripture for the zeal he showed in vindicating the glory of God, when the Midianites had sent their daughters into the camp of Israel, to tempt the Hebrews to fornication and idolatry. For Zimri having publicly entered into the tent of a Midianitish woman named *Cozbi*, Phinehas arose up from among the people (Numb. xxv. 7, &c.), took a javelin in his hand, entered after Zimri into that infamous place, and stabbed both man and woman at one blow, in those parts that were chiefly concerned in this criminal commerce. Upon which the plague or distemper ceased with which the Lord had already begun to punish the Israelites. This happened in the year of the world 2553.

Then the Lord said to Moses, Phinehas the son of Eleazar the high-priest has turned away my wrath from the children of Israel, because he has been zealous in my cause, and has hindered me from destroying them: wherefore acquaint him, that I give him my covenant of peace, and the priesthood shall be given to his posterity by a perpetual covenant, because he has been zealous for his God, and has made atonement for the crime of the children of Israel. This promise that the Lord made to Phinehas, to give him the priesthood by a perpetual covenant, interpreters observe, evidently included this tacit condition, that his children should continue faithful and obedient; since we know that the priesthood passed out of the family of Eleazar and Phinehas to that of Ithamar, and that it returned not to the posterity of Eleazar till after about 150 years.

This is what we find concerning the translation of

the high-priesthood from one family to the other. This dignity continued in the race of Phinehas, from Aaron down to the high-priest Eli, for about 335 years. See AARON.

The manner and causes of this change are unknown. It re-entered again into the family of Eleazar under the reign of Saul, when this prince having put to death Abimelech, and the other priests of Nob, he gave the high-priesthood to Zadok, who was of the race of Phinehas. At the same time, David had Abiathar with him, of the race of Eli, who performed the functions of high-priest. So that after the death of Saul, David continued the priesthood to Zadok and Abiathar conjointly. But towards the end of David's reign, Abiathar having espoused the interest of Adonijah, to the prejudice of Solomon, he was in disgrace, and Zadok only was acknowledged as high-priest. The priesthood continued in his family till after the captivity of Babylon, and even to the destruction of the temple. But from the beginning of Zadok's priesthood alone, and the exclusion of Abiathar, to the ruin of the temple, is 1084 years.

We read of another memorable action of Phinehas, in which he still showed his zeal for the Lord. This was when the Israelites that were beyond Jordan had raised upon the banks of this river a vast heap of earth (Josh. xxii. 30, 31.). Those on the other side fearing they were going to forsake the Lord, and set up another religion, deputed Phinehas and other chief men among them, to go and inform themselves of the reason of erecting this monument. But when they had found that it was in commemoration of their union and common original, Phinehas took occasion from thence to praise the Lord, saying, "We know that the Lord is with us, since you are not guilty of that prevarication we suspected you were."

We do not exactly know the time of the death of Phinehas. But as he lived after the death of Joshua, and before the first servitude under Chusshan-rishathaim, during the time that there were neither kings nor judges in the land, and every one did what was right in his own eyes (Judges xvii. 6. xviii. 1. xxi. 24.); his death is put about the year of the world 2590. It was under his pontificate that the story of Micah happened, as also that of the tribe of Dan, when they made a conquest of Laish; and the enormity that was committed upon the wife of the Levite of the mountain of Ephraim (Judges xx. 28.). Phinehas's successor in the high-priesthood was Abiezer, or Abihuah.

The Rabbins allow a very long life to Phinehas. There are some who believe he lived to the time of the high-priest Eli, or even to the time of Samson. Others will have it, that he was the same as Eli, or rather as the prophet Elias, which would still prolong his life for several ages.

PHINEUS (fab. hist.), was a son of Agenor, king of Phœnicia, or according to some of Neptune. He became king of Thrace, or, according to the greater part of mythologists, of Bithynia. He married Cleopatra the daughter of Boreas, called by some *Cleobula*, by whom he had Plexippus and Pandion. After her death, he married Idæa the daughter of Dardanns. Idæa, jealous of his former wife's children, accused them of attempts upon their father's life and crown, or, as others assert, of attempts upon her virtue; on which they were condemned by Phi-

Phinehas,
Phineus.

Phlebotomy or **Phlegon**. Phinehas to be deprived of their eyes. This cruelty was soon after punished by the gods; for Phinehas suddenly became blind, and the Harpies were sent by Jupiter to keep him in continual alarm, and to spoil the meats which were placed on his table. He was afterwards delivered from these dangerous monsters by his brothers-in-law Zetes and Calais, who pursued them as far as the Strophades. He likewise recovered his sight by means of the Argonauts, whom he had received with great hospitality, and whom he instructed in the easiest and speediest way of arriving in Colchis. The causes of the blindness of Phineus are a matter of dispute among the ancients; some supposing that this was inflicted by Boreas for his cruelty to his grandson; while others attribute it to the anger of Neptune, because he had directed the sons of Phryxus how to escape from Colchis to Greece. Many, however, imagine that it proceeded from his having rashly attempted to develop futurity; while others assert that Zetes and Calais put out his eyes on account of his cruelty to their nephews. The second wife of Phineus is called by some *Dia*, *Eurytia*, *Danea*, and *Idothea*.—He was killed by Hercules.

PHLEBOTOMY, the opening of a vein with a proper sharp-edged and pointed instrument, in order to let out a certain quantity of blood either for the preservation or recovery of a person's health. See **SURGERY**.

PHLEGM, in the animal economy, one of the four humours whereof the ancients supposed the blood to be composed. The chemists make phlegm or water an elementary body; the characters of which are fluidity, insipidity, and volatility.

PHLEGMAGOGUES, in medicine, a term anciently made use of for such medicines as were supposed to be endowed with the property of purging off phlegm; such as hermodactyls, agaric, turbiti, jalap, &c.

PHLEGMATIC, among physicians, an appellation given to that habit or temperament of body wherein phlegm is predominant; which gives rise to catarrhs, coughs, &c.

PHLEGMON, denotes an external inflammation and tumor, attended with a burning heat.

PHLEGON, who was surnamed *Trallianus*, was born in Trallis a city of Lydia. He was the emperor Hadrian's freed man, and lived to the 18th year of Antoninus Pius; as is evident from his mentioning the consuls of that year. He wrote several works of great erudition, of which we have nothing left but fragments. Among these was a History of the Olympiads, A Treatise of Long-lived Persons, and another of Wonderful Things; the short and broken remains of which Xylander translated into Latin, and published at Basil in 1568, with the Greek and with notes. Meursius published a new edition of them with his notes at Leyden, in 1622. The titles of part of the rest of Phlegon's writings are preserved by Suidas. It is supposed that the History of Hadrian, published under Phlegon's name, was written by Hadrian himself, from this passage of Spartianus: "Hadrian thirsted so much after fame (says he), that he gave the books of his own life, drawn up by himself, to his freemen, commanding them to publish those books under their own names; for we are told that Hadrian wrote Phlegon's books."

Phlegon's name has been more familiar among the

moderns, and his fragments have had a greater degree of regard paid to them than perhaps they deserve, merely because he has been supposed to speak of the darkness which prevailed during our Lord's passion. The book in which the words are contained is lost; but Eusebius has preserved them in his *Chronicon*. These are these: "In the 4th year of the 202d Olympiad, there was a greater and more remarkable eclipse of the sun than any that had ever happened before: for at the sixth hour the day was so turned into the darkness of night, that the very stars in the firmament were visible; and there was an earthquake in Bithynia which threw down many houses in the city of Nicæa." Eusebius thinks that these words of Phlegon related to the prodigies which accompanied Christ's crucifixion; and many other fathers of the church have thought the same: but this opinion is liable to many difficulties; for no man had ever a stronger desire than Phlegon to compile marvelous events, and to observe the supernatural circumstances in them. How was it then possible that a man of this turn of mind should not have taken notice of the most surprising circumstance in the eclipse which it is imagined he hints at, viz. its happening on the day when the moon was at the full? But had Phlegon done this, Eusebius would not have omitted it; and Origen would not have said that Phlegon had omitted this particular.

It was a matter of controversy some time ago, whether Phlegon really spoke of the darkness at the time of our Lord's passion; and many dissertations were written on both sides of the question. This dispute was occasioned by the above passage from Phlegon being left out in an edition of Clark's Boyle's Lectures, published after his death, at the instance of Sykes, who had suggested to Clarke, that an undue stress had been laid upon it. Whiston, who informs us of this affair, expresses great displeasure against Sykes, and calls "the suggestion groundless." Upon this, Sykes published "A Dissertation on the Eclipse mentioned by Phlegon: or, An Inquiry whether that Eclipse had any relation to the darkness which happened at our Saviour's Passion, 1732," 8vo. Sykes concludes it to be most probable that Phlegon had in view a natural eclipse which happened November 24. in the 1st year of the 202d Olympiad, and not in the 4th year of the Olympiad in which Christ was crucified. Many pieces were written against him, and to some of them he replied; but perhaps it is a controversy which concerns the learned world merely, since the cause of religion is but little affected by it.

Photius blames Phlegon for expatiating too much on trifles, and for collecting too great a number of answers pronounced by the oracles. "His style (he tells us) is not altogether flat and mean, nor does it everywhere imitate the Attic manner of writing. But otherwise, the over nice accuracy and care with which he computes the Olympiads, and relates the names of the contests, the transactions, and even oracles, is not only very tiresome to the reader, whereby a cloud is thrown over all other particulars in that book, but the diction is thereby rendered unpleasant and ungrateful; and indeed he is every moment bringing in the answers pronounced by all kinds of deities."

PHLOGISTON, a term used by chemists to express a principle which was supposed to enter the composition of various bodies.

Phlogiston. The bodies which were thought to contain it in the largest quantity are the inflammable substances; and the property which these substances possess of being susceptible of inflammation was thought to depend on this principle; and hence it was sometimes called the *Principle of Inflammability*. Inflammation, according to this doctrine, was the separation of *this principle* or *phlogiston* from the other matter which composed the combustible body. As its separation was always attended with the emission of light and heat, some of the chemists concluded that it was light and heat combined with other matter in a peculiar manner, or that it was some highly elastic and very subtle matter, on certain modifications of which heat and light depended.

Another class of bodies which were supposed to contain phlogiston are the metals; and the chemists supposed that the peculiar lustre of the metals depended on this principle. Of this they thought themselves convinced by the evidence of their senses in two ways; viz. first, because by exposing a metal to the action of a long continued heat, it lost its metallic lustre, and was converted into an earthy-like substance called *calx metallicus*; and secondly, because by mixing this calx with any inflammable substance whatever, and subjecting the mixture to certain operations, the inflammable matter disappeared, and the metal was restored to its former state and lustre, without suffering much diminution in quantity, especially if the processes had been conducted with care and attention.

This fact relative to the metals was thought to be a full demonstration of itself, independent of other proofs which were brought to support the doctrine. These were, that a combustible body, by the act of inflammation (*i. e.* by the dissipation of its phlogiston in the form of heat and light), was converted into a body that was no longer combustible, but which might have its property of combustibility restored to it again by mixing the incombustible remains with any kind of inflammable matter, and submitting the mixture to certain processes. In this way the body was restored to its former state of inflammability.

They were also at some pains to prove that the *phlogiston* or the *principle of inflammability* was the same in all inflammable bodies and in the metals. This identity of phlogiston they thought to be evident from the fact, that the calx of a metal might be restored to its metallic state, or that the remains after the combustion of a combustible body might be again restored to its original state of combustibility by the addition of any inflammable body whatever, taken either from the animal, vegetable, or mineral kingdoms.

These and several other facts were brought to prove, not only the existence of phlogiston, but its effects in mixture with other substances: and the objections which were made against the doctrine were removed with wonderful ingenuity. The chief objection against it was, that if the inflammation of a combustible body, or the conversion of a metal into calx, depends on the dissipation or extrication of Phlogiston; then it must follow, that the remains of a combustible body after inflammation, and the calx of the metal, must be less than the matter from which they were produced; but this is contrary to fact; for when we collect with care all the vapour into which the purest inflammable bodies are converted by combustion, these incombustible

remains are much heavier than the inflammable body Phlogiston. was from which they were produced, and the calx into which a metal is converted by long exposure to the action of heat is heavier than the metal from which it was produced. This consideration made several people doubt of the truth of the doctrine; but the objection was removed by saying, that phlogiston was so subtle, as not only to have no weight, but to possess an absolute levity; and that when it was taken from an absolutely heavy body, that body must, by losing so much absolute levity, become heavier, in the same manner as the algebraists say, that a positive quantity is augmented by the subtraction of a negative quantity. This philosophy satisfied the minds of most of the chemists, especially those who were algebraists.

The opinion that phlogiston was heat and light somehow combined with other matter, was proved, not only by the fact, that heat and light were emitted from a combustible body during its combustion, but from the reduction of certain metallic calces to their original metallic state again, at least in some degree, by simple exposure to heat and light. The white calx of silver for instance, when exposed in close sealed glass vessels to the light and heat of the sun, resumes a black tinge, and is in part restored to its metallic lustre without any addition whatever; but then this restoration, like the others above mentioned, is attended with a loss of weight.

Besides constituting the principal part of inflammable bodies and metals, phlogiston was thought to be the cause of colour in all vegetable and animal substances. This was concluded from the fact of plants growing white when defended from the action of the sun's rays, and in having their green colour restored by exposure to his rays again; and so far did the chemists suffer themselves to be deceived, that they actually thought the green colouring matter, which they extracted from fresh plants by certain chemical processes, to be an inflammable substance. A very material objection was made to this argument, viz. if plants owe their colour to phlogiston imparted by the sun's rays, why do the sun's rays destroy vegetable colours that are exposed to them? for we know that the sun's rays are very effectual in diminishing the lustre of cloth dyed with vegetable colours, and in bleaching or taking out various stains from linen and other substances. All this was removed by saying, that the sun's rays possessed different powers on living and on dead vegetable matter, and that the living vegetables had the power of absorbing phlogiston from the sun's rays, which dead vegetable matter had not.

Since the existence of phlogiston, as a chemical principle in the composition of certain bodies, is now fully proved to be false, we shall not trouble our readers with any farther observations on it, except adding, that although the chemists were satisfied with the proofs they gave of its reality, they were never able to exhibit it in a separate state, or show it in a pure form, unmixed with other matter.

Phlogiston seems to have been admitted as a principle in the composition of certain bodies, and to have been supposed the cause of certain modifications of matter, merely with a view to explain some of those natural phenomena which the authors of it were unable to explain on other principles. Subsequent discoveries in natural philosophy and in chemistry have

Phlogiston. represented things: in a very different light from that in which the old chemists viewed them. The old chemists knew nothing but chemistry; they seldom extended their views to the observation of objects beyond their laboratories, and it was not till philosophers became chemists, and chemists philosophers, that chemistry began to wear the garb of science. The epoch in which this change began was in the time of Lord Verulam, who first removed the dimness from the chemist's eyes, and to him succeeded the Honourable Mr Boyle. Sir Isaac Newton, with the little assistance which his predecessors in this branch of science afforded him, is in reality the first who established chemistry on scientific ground. It must, however, be acknowledged, that although he made a great progress, he left much undone; and subsequent chemists, who were less accurate observers of nature, admitted principles unwarrantably. From the time of Sir Isaac Newton till the middle of the 18th century, no real improvement was made in scientific chemistry; and the progress this science has made since that period is owing to the important discovery of the existence of heat in a state of composition with other matter. Heat thus combined loses its activity or becomes insensible, just in the same way as any other active substance loses its apparent qualities in composition. Acids, for example, when combined in a certain proportion with substances for which they have strong attraction, as alkalis or absorbent earths, lose all their obvious acid qualities, and the compound turns out mild, and totally conceals the acid which it contains. In a similar manner, heat, when combined in certain proportions with other matter, loses its sensible qualities, and the compound conceals the heat which it contains. Heat, in this combined state, was called by its ingenious discoverer, Dr Black, *latent heat*, and it was found to be very abundant in the atmosphere, which owes its existence as an elastic fluid to the quantity of latent heat that it contains. After this discovery was made, Dr Crawford, considering that air was absorbed by a burning body, concluded that the heat which appears in the combustion of a combustible body, is the heat that had before existed in the air which was consumed by the burning body. Mr Lavoisier and others, prosecuting this inquiry, found that the combustible body, while it is burning, unites with the basis of the air, and that the heat which the air contained, and which was the cause of the air existing in the state of air, is expelled. This absorption of the basis of the air by the burning body, and the reduction of this basis to a solid form, accounts for the increase of weight which a body acquires by burning; or, in other words, gives a reason why the matter into which a combustible body is converted by combustion, is heavier than the body from which it was produced. The same absorption of air is observable, when a metal is converted into a calx, and the additional weight of the calx is found to be precisely equal to the weight of the air absorbed during the calcination. On these principles, therefore, we now explain the phenomena in a much more satisfactory manner than by the supposition of phlogiston, or a principle of inflammability.

This theory is more fully elucidated in several articles in the former part of this work; we shall not, therefore, in this place, repeat what the reader may

find under the words HEAT, INFLAMMATION, FLAME, Phlogiston. CHEMISTRY, CALCINATION of Metals, OXYGEN, &c. Phlogiston.

PHLOGONIAE, a class of compound, inflammable, and metallic fossils, found in small masses of determinately angular figures; comprehending the pyricubia, pyroctogonia, and pyripolygonia.

PHLOMIS, the SAGE TREE, or *Jerusalem Sage*; a genus of the gymnospermia order, belonging to the didynamia class of plants. There are 14 species, all of which have perennial roots, and of many the stalks also are perennial. The latter rise from two to five or six feet high; and are adorned with yellow, blue or purple flowers in whorls. They are all ornamental plants; and deserve a place in gardens, as they are sufficiently hardy to endure the ordinary winters in this climate: they require, however, a pretty warm situation.

There are two species of this plant, which are peculiarly adapted to the shrubbery, viz. the *Phlomis fruticososa*, a native of Spain and Sicily, and the *Phlomis purpurea*. Of the first species there are three varieties, 1. *The broad-leaved Jerusalem Sage-tree*, is now very common in our gardens. Its beauty is great, and its culture very easy. It grows to be about five feet high, and spreads its branches without order all around. The older branches are covered with a dirty, greenish, dead, falling, ill-looking bark; and this is the worst property of this shrub: but the younger shoots are white and beautiful; they are four-cornered, woolly, and soft to the touch. The leaves are roundish and oblong, and moderately large; and these grow opposite at the joints of the shrub on long footstalks. They are hoary to a degree of whiteness, and their footstalks also are woolly, white, tough, and strong. The flowers are produced in June, July, and August, at the top joints of the young shoots, in large whorled bunches. They are of the labiated kind, each consisting of two lips, the upper end of which is forked, and bends over the other. A finer yellow can hardly be conceived than the colour of which they are possessed; and being large, they exhibit their golden flowers at a great distance, causing thereby a handsome show. 2. *The narrow-leaved Jerusalem Sage tree*, is of lower growth than the other, seldom rising higher than a yard or four feet. This shrub is in every respect like the other; only the shoots seem to have a more upright tendency of growth. The leaves also, which are narrower, are more inclined to a lanceolate form: They are numerous in both the sorts, and hide the deformity of the bark on the older stems, which renders them less exceptionable on that account. In short, these sorts are qualified for shrubberies of all kinds, or to be set in borders of flower-gardens, where they will flower, and be exceeded even in that respect by very few shrubs. 3. *Cretan Sage-tree*, is still of lower growth than either of the former, seldom arising to a yard in height. The leaves are of the same white hoary nature; they are very broad, and stand on long footstalks. The flowers are also of a delightful yellow colour, very large, and grow in large whorls, which give the plant great beauty.

The second species, which is *Purple Phlomis* or *Portugul Sage*, is four feet high; the stalks are woody, and send forth several angular branches, which are covered with a white bark. The leaves are spear-shaped,

and Orna-
mental
Gardening.

Phlomis
||
Phoca.

ped, oblong, woolly underneath, crenated, and grow on short footstalks. The flowers are produced in whorls from the joints of the branches. They are of a deep purple colour, and have narrow involucre. They appear in June and July, but are not succeeded by ripe seeds in England. There is a variety of this species with iron-coloured flowers, and another with flowers of a bright purple.

There are some other shrubby sorts of phlomis, of great beauty; but these not only often lose their leaves, and even branches, from the first frost, but are frequently wholly destroyed, if it happens to be severe. They are low shrubs, very beautiful, and look well among perennial flowers, where they will not only class us to size with many of that sort, but, being rather tender, may with them have such extraordinary care as the owner may think proper to allow them.

The propagation of the above sorts is, as we have already hinted, very easy, and is accomplished either by layers or cuttings. 1. If a little earth be thrown upon the branches any time in the winter, they will strike root and be good plants by the autumn following, fit for any place. Thus easy is the culture by that method. 2. The cuttings will also grow, if planted any time of the year. Those planted in winter should be the woody shoots of the former summer: These may be set close in a shady border; and being watered in dry weather, will often grow. This shrub may be propagated by young slips also, in any of the summer months. These should be planted in a shady border, like sage, and well watered. If the border is not naturally shady, the beds must be hooped, and covered with matting in hot weather. Watering must be constantly afforded them; and with this care and management many of them will grow.

PHLOX, LYCHNIDEA, or *Bastard Lychnis*; a genus of the monogynia order, belonging to the pentandria class of plants. There are seven species, all of them natives of North America. They have perennial roots, from which arise herbaceous stalks from nine inches to two feet in height, adorned with tubulated flowers of a purple colour. They are propagated by offsets, and will bear the winters in this country. They require a moist rich soil, in which they thrive better and grow taller than in any other.

PHLYCTENÆ, in medicine, small eruptions on the skin.

PHOCA, in zoology, a genus of quadrupeds of the order of fere. There are six parallel fore-teeth in the upper jaw, the outermost being larger; and four blunt, parallel, distinct, equal fore-teeth in the under jaw. There is but one dog-tooth, and five or six three-pointed grinders; and the hind feet are united so as to resemble a sheep's tail. There are a variety of species, the principle of which are,

1. The ursina, sea-bear, or ursine seal, has external ears. The male is greatly superior in size to the female. The bodies of each are of a conic form, very thick before, and taper to the tail. The length of a large one is

eight feet; the greatest circumference, five feet; near the tail, 20 inches; and the weight is about 800 lb. The nose projects like that of a pug-dog, but the head rises suddenly; the teeth lock into one another when the mouth is shut; the tongue is large; the eyes are large and prominent, and may be covered at pleasure by a fleshy membrane. The length of the fore-legs is 24 inches; they are like those of other quadrupeds, not immersed in the body like those of seals; the feet are formed with toes like those of other animals, but are covered with a naked skin, so that externally they seem to be a shapeless mass; the hind-legs are fixed to the body quite behind, like those of common seals; but are capable of being brought forward, so that the animal makes use of them to scratch its head.

These animals are found in the northern seas. They are found in amazing quantities between Kamtschatka and America; but are scarcely known to land on the Asiatic shore: nor are they ever taken except in the three Kurilian islands, and from thence in the Bobrowie More, or Beaver Sea, as far as the Kronoski headland, off the river Kamtschatka, which comprehends only from 50 to 56 north latitude. It is observable that they never double the southern cape of the peninsula, or are found on the western side in the Penschinska sea: but their great resort has been observed to be to Bering's islands. They are as regularly migratory as birds of passage. They first appear off the three Kurili islands and Kamtschatka in the earliest spring. There is not one female which does not come pregnant. Such as are then taken are opened, the young taken out and skinned. They are found in Bering's island only on the western shore, being the part opposite to Asia, where they first appear on their migration from the south.

Ursine seals are also found in the southern hemisphere, even from under the line, in the isle of Gallipagos (A), to New Georgia, in south latitude 54. 15. and west longitude 37. 15. In the intermediate parts, they are met with in New Zealand, in the isle of Juan Fernandez, and its neighbour Massa Fuera, and probably along the coasts of Chili to Terra del Fuego and Staten Land. In Juan Fernandez, Staten Land, and New Georgia, they swarm; as they do at the northern extremity of this vast ocean. Those of the southern hemisphere have also their seasons of migration.—Alexander Selkirk, who passed three lonely years on the isle of Juan Fernandez, remarks that they come ashore in June, and stay till September. Captain Cook found them again in their place of remigration in equal abundance, on Staten Land and new Georgia in the months of December and January; and Don Perney found them on the Falkland islands in the month of February. According to the Greenlanders, this species inhabits the southern parts of their country. They call it *Aurkekejak*. That it is very fierce, and tears to pieces whatsoever it meets; that it lives on land as well as in water, and is greatly dreaded by the hunters.

During the three months of summer they lead a most indolent

Phoca.

(A) *Wooles Roger's Voy.* 265. He says that they are neither so numerous there, nor is their fur so fine, as those on Juan Fernandez, which is said to be extremely soft and delicate.

Phoca. indolent life: they arrive at the islands vastly fat; but during that time they are scarce ever in motion, confine themselves for whole weeks to one spot, sleep a great part of the time, eat nothing, and, except the employment the females have in suckling their young, are totally inactive. They live in families: each male has from 8 to 50 females, whom he guards with the jealousy of an eastern monarch; and though they lie by thousands on the shores, each family keeps itself separate from the rest, and sometimes, with the young and unmarried ones, amount to 120. The old animals, which are destitute of females, or deserted by them, live apart, and are excessively splenetick, peevish, and quarrelsome: are exceeding fierce, and so attached to their old haunts, that they would die sooner than quit them. They are monstrously fat, and have a most hireine smell. If another approaches their station, they are roused from their indolence, and instantly snap at it, and a battle ensues; in the conflict, they perhaps intrude on the seat of another: this gives new cause of offence, so in the end the discord becomes universal, and is spread through the whole shore.

The other males are also very irascible: the causes of their disputes are generally these. The first and most terrible is, when an attempt is made by another to seduce one of their mistresses or a young female of the family. This insult produces a combat; and the conqueror is immediately followed by the whole seraglio, who are sure of deserting the unhappy vanquished. The second reason of a quarrel is, when one invades the seat of another: the third arises from their interfering in the disputes of others. These battles are very violent; the wounds they receive are very deep, and resemble the cuts of a sabre. At the end of a fight they fling themselves into the sea, to wash away the blood.

The males are very fond of their young, but very tyrannical towards the females; if any body attempts to take their cub, the male stands on the defensive, while the female makes off with the young in her mouth; should she drop it, the former instantly quits his enemy, falls on her, and beats her against the stones, till he leaves her for dead. As soon as she recovers, she comes in the most suppliant manner to the male, crawls to his feet, and washes them with her tears: he, in the mean time, stalks about in the most insulting manner; but in case the young one is carried off, he melts into the deepest affliction, and shows all signs of extreme concern. It is probable that he feels his misfortunes the more sensibly, as the female generally brings but one at a time, never more than two.

They swim very swiftly, at the rate of seven miles an hour. If wounded, they will seize on the boat, and carry it along with vast impetuosity, and oftentimes sink it. They can continue a long time under water. When they want to climb the rocks, they fasten with the fore-paws, and so draw themselves up. They are very tenacious of life, and will live for a fortnight after receiving such wounds as would immediately destroy any other animal.

The Kamtschatkans take them by harpooning, for they never land on their shore. To the harpoon is fastened a long line, by which they draw the animal to the boat after it is spent with fatigue; but in the

chase, the hunters are very fearful of too near an approach, lest the animal should fasten on, and sink their vessel.

The uses of them are not great. The flesh of the old males is rank and nauseous; that of the females is said to resemble lamb; of the young ones roasted, a sucking pig. The skins of the young, cut out of the bellies of the dams, are esteemed for cloathing, and are sold for about three shillings and fourpence each; those of the old for only four shillings.

Their remigration is in the month of September, when they depart excessively lean, and take their young with them. On their return, they again pass near the same parts of Kamtschatka which they did in the spring. Their winter retreats are quite unknown; it is probable that they are the islands between Kurili and Japan, of which we have some brief accounts, under the name of *Compagnie Land*, *States Land*, and *Jeso Gasima*, which were discovered by Martin Uriel in 1642. It is certain, that by his account the natives employed themselves in the capture of seals. Sailors do not give themselves the trouble of observing the nice distinction of specific marks; we are therefore at liberty to conjecture those which he saw to be our animals, especially as we can fix on no more convenient place for their winter quarters. They arrive along the shores of the Kurili islands, and part of those of Kamtschatka, from the south. They land and inhabit only the western side of Bering's isle which faces Kamtschatka; and when they return in September, their rout is due south, pointing towards the discoveries of Uriel. Had they migrated from the south-east as well as the south-west, every isle, and every side of every isle, would have been filled with them; nor should we have found (as we do) such a constant and local residence.

2. The leonina, sea-lion, or bottienose, is found near the south pole. One variety of this species is described at some length by the publisher of Anson's voyage. However, according to others who have written on this subject, the name of *sea-lion* belongs not so properly to this as to another, which has a mane like a true lion. Of these we have the following account from Pernety's Historical Journal. "The hair that covers the back part of the head, neck, and shoulders, is at least as long as the hair of a goat. It gives this amphibious animal an air of resemblance to the common lion of the forest, excepting the difference of size. The sea-lions of the kind I speak of are 25 feet in length, and from 19 to 20 in their greatest circumference. In other respects they resemble the common sea-lions. Those of the small kind have a head resembling a mastiff's with close cropt ears.

"The teeth of the sea-lions which have manes, are much larger and more solid than those of the rest. In these, all the teeth which are inserted into the jaw-bone are hollow. They have only four large ones, two in the lower and two in the upper jaw. The rest are not even so large as those of a horse. I brought home one belonging to the true sea-lion, which is at least three inches in diameter, and seven in length, though not one of the largest. We counted 22 of the same sort in the jaw-bone of one of these lions, where five or six were wanting. They were entirely solid, and projected scarce more than an inch, or an inch and a half

Pieces. a half beyond their sockets. They are nearly equal in solidity to flint, and are of a dazzling white. Several of our seamen took them for white flints when they found them upon the shore. I could not even persuade them that they were not real flints, except by rubbing them against each other, or breaking some pieces off, to make them sensible that they exhaled the same smell as bones and ivory do when they are rubbed or scraped.

"These sea-lions that have manes are not more mischievous or formidable than the others. They are equally unwieldy and heavy in their motions; and are rather disposed to avoid than to fall upon those who attack them. Both kinds live upon fish and water-fowl, which they catch by surprise. They bring forth and suckle their young ones among the corn flags, where they retire at night, and continue to give them suck till they are large enough to go to sea. In the evening you see them assembling in herds upon the shore, and calling their dams in cries so much like lambs, calves, and goats, that, unless apprized of it, you would easily be deceived. The tongue of these animals is very good eating: we preferred it to that of an ox or calf. For a trial we cut off the tip of the tongue hanging out of the mouth of one of these lions which was just killed. About 16 or 18 of us eat each a pretty large piece, and we all thought it so good, that we regretted we could not eat more of it.

"It is said that their flesh is not absolutely disagreeable. I have not tasted it: but the oil which is extracted from their grease is of great use. This oil is extracted two ways; either by cutting the fat in pieces, and melting it in large caldrons upon the fire; or by cutting it in the same manner upon hurdles, or pieces of board, and exposing them to the sun, or only to the air: this grease dissolves of itself, and runs into vessels placed underneath to receive it.—Some of our seamen pretended, that this last sort of oil, when it is fresh, is very good for kitchen uses: this, as well as the other, is commonly used for dressing leather for vessels, and for lamps. It is preferred to that of the whale: it is always clear, and leaves no sediment.

"The skins of the sea lions are used chiefly in making portmanteaus, and in covering trunks. When they are tanned, they have a grain almost like Morocco. They are not so fine, but are less liable to tear, and keep fresh a longer time. They make good shoes and boots, which, when well seasoned, are water-proof.

"One day Mr Guyot and some others brought on board five sea-lionesses. They were about seven feet long, and three and a half in circumference, tho' their intestines were drawn. These gentlemen had landed on a small island, where they found a prodigious number of these animals, and killed eight or nine hundred of them with sticks. No other weapon is necessary on these occasions. A single blow with a bludgeon, three feet or three feet and a half long, almost full at the nose of these animals, knocks them down, and kills them on the spot.

"This is not altogether the case with the males: their size is prodigious. Our gentlemen encountered two of them for a long time, with the same weapons, without being able to overcome them. They lodged

three balls in the throat of one while he opened his mouth to defend himself, and three musket-shot in his body. The blood gushed from his wounds like wine from a tap. However, he crawled into the water and disappeared. A sailor attacked the other, and engaged him for a long time, striking him on the head with a bludgeon, without being able to knock him down: the sailor fell down very near his antagonist, but had the dexterity to recover himself at the instant the lion was going to gorge him. Had he once seized him, the man would infallibly have been lost: the animal would have carried him into the water as they usually do their prey, and there feasted upon him. In his retreat to the sea this animal seized a penguin, and devoured him instantaneously."

Mr Pennant describes three seals of different species which are called *sea-lions*, viz. the *phoca leonina*, or hooded seal; the *phoca leonina*, or bottlenose; and the *bestia marina*, or leonine seal. He differs in some particulars from the author just quoted; and such of our readers as desire to know these differences, we refer to his works.

3 The vitulina, sea calf, or common seal, inhabits the European ocean. It has a smooth head without external ears; and the common length is from five to six feet. The fore legs are deeply immersed in the skin of the body; the hind legs are placed in such a manner as to point directly backwards: every foot is divided into five toes; and each of those connected by a strong and broad web, covered on both sides with short hair. The toes are furnished with strong claws, well adapted to assist the animal in climbing the rocks it basks on; the claws on the hind feet are slender and straight; except at the ends, which are a little incurvated. The head and nose are broad and flat, like those of the otter; the neck short and thick; the eyes large and black; in lieu of external ears, it has two small orifices: the nostrils are oblong: on each side the nose are several long stiff hairs; and above each eye are a few of the same kind. The form of the tongue is so singular, that were other notes wanting, that alone would distinguish it from all other quadrupeds; being forked, or slit at the end. The cutting teeth are singular in respect to their number, being six in the upper jaw, and only four in the lower. It has two canine teeth above and below, and on each side of the jaw five grinders; the total 34. The whole animal is covered with short hair, very closely set together: the colour of that on the body is generally dusky, spotted irregularly with white; on the belly white; but seals vary greatly in their marks and colours, and some have been found entirely white.

The seal is common on most of the rocky shores of Great Britain and Ireland, especially on the northern coasts: in Wales, it frequents the coasts of Caernarvonshire and Anglesey. They inhabit all the European seas, even to the extreme north; are found far within the arctic circle, in the seas both of Europe and Asia, and are even continued to those of Kamtschatka*.

* Steller. in Nov. Com. Pa-trop. ii. 290.

power

Phoca, power of oil in stilling the waves excited by a storm is mentioned by Pliny: the moderns have made the experiment with success; and thereby made one advance towards eradicating the vulgar prejudices against that great and elegant writer.

Seals are excellent swimmers, and ready divers; and are very bold when in the sea, swimming carelessly enough about boats; their dens or lodgments are in hollow rocks or caverns near the sea, but out of the reach of the tide: in the summer they will come out of the water, to bask or sleep in the sun on the top of large stones or shivers of rocks; and that is the opportunity our countrymen take of shooting them: if they chance to escape, they hasten towards their proper element, flinging stones and dirt behind them as they scramble along; at the same time expressing their fears by piteous moans; but if they happen to be overtaken, they will make a vigorous defence with their feet and teeth till they are killed. They are taken for the sake of their skins, and for the oil their fat yields: the former sell for 4 s. or 4 s. 6 d. a piece; which, when dressed, are very useful in covering trunks, making waistcoats, shot-pouches, and several other conveniences. We remember some years ago to have seen a young seal in some degree domesticated. It was taken at a little distance from the sea, and was generally kept in a vessel full of salt water; but sometimes it was allowed to crawl about the house, and even to approach the fire. Its natural food was regularly procured for it, and it was taken to the sea every day and thrown in from a boat. It used to swim after the boat, and always allowed itself to be taken back. It lived thus for several weeks; and we doubt not would have lived much longer had it not been sometimes too roughly used by the boys who took it to and from the sea.

The flesh of these animals, and even of porpoises, formerly found a place at the tables of the great; as appears from the bill of fare of that vast feast that Archbishop Nevill gave in the reign of Edward IV. in which is seen that several were provided on the occasion. They couple about April, on large rocks or small islands not remote from the shore; and bring forth in those vast caverns that are frequent on the coasts: they commonly bring two at a time, which in their infant state are covered with a whitish down or woolly substance. The seal hunters in Caithness say, that their growth is so sudden, that in nine tides from their birth (108 hours) they will become as active as their parents. On the coast of that country are immense caverns opening into the sea, and running some hundreds of yards beneath the land. These are the resort of seals in the breeding time, where they continue till their young are old enough to go to sea, which is in about six or seven weeks. The first of these caves is near the Ord, the last near Thurminster; their entrance is so narrow as only to admit a boat; their inside very spacious and lofty. In the month of October, or the beginning of November, the seal hunters enter the mouth of the caverns about midnight, and rowing up as far as they can, they land; each of them being provided with a bludgeon, and properly stationed, they light their torches, and make a great noise, which brings down the seals from the farther end in a confused body with fearful shrieks and cries: at first the men are obliged to give way for fear of being overborne; but when

Vol. XIV.

the first crowd is past, they kill as many as straggle behind, chiefly the young, by striking them on the nose; a very slight blow on that part dispatches them. When the work is over, they drag the seals to the boat, which two men are left to guard. This is a most hazardous employment; for should their torches go out, or the wind blow hard from sea during their continuance in the cave, their lives are lost. The young seal's of six weeks age yield more oil than their emaciated dams: above eight gallons have been got from a single whelp, which sells from 6 d. to 9 d. per gallon; the skins from 6 d. to 1 s. each.

The natural history of this animal may be further elucidated by the following extracts from a letter of the reverend Dr William Boilafe, dated October the 24th 1763. "The seals are seen in the greatest plenty on the shores of Cornwall in the months of May, June, and July. They are of different sizes; some as large as a cow, and from that downwards to a small calf. They feed on most sorts of fish which they can master; and are seen searching for their prey near shore, where the whistling fish, wraws, and pollocks, resort. They are very swift in their proper depth of water, dive like a shot, and in a trice rise at 50 yards distance; so that weaker fishes cannot avoid their tyranny except in shallow water. A person of the parish of Sennan saw not long since a seal in pursuit of a mullet (that strong and swift fish); the seal turned it to and fro in deep water, as a greyhound does a hare; the mullet at last found it had no way to escape, but by running into shoal water: the seal pursued; and the former, to get more surely out of danger, threw itself on its side, by which means it darted into shoaler water than it could have swam in with the depth of its paunch and fins, and so escaped. The seal brings her young about the beginning of autumn: our fishermen have seen two sucking their dam at the same time, as the stood in the sea in a perpendicular position. Their head in swimming is always above water, more so than that of a dog. They sleep on rocks surrounded by the sea, or on the less accessible parts of the cliffs left dry by the ebb of the tide; and if disturbed by any thing, take care to tumble over the rocks into the sea. They are extremely watchful, and never sleep long without moving; seldom longer than a minute; then raise their heads, and if they hear or see nothing more than ordinary, lie down again, and so on, raising their heads a little and reclining them alternately in about a minute's time. Nature seems to have given them this precaution, as being unprovided with auricles or external ears; and consequently not hearing very quick, nor from any great distance."

These animals are so very useful to the inhabitants of Greenland and other arctic people, that they may be called their flocks. We cannot give a better account of these uses than in the words of Mr Crantz, who was long resident in those northern regions.

"Seals (says he) are more needful to them than sheep are to us, though they furnish us with food and raiment; or than the cocoa-tree is to the Indian, although that presents them not only with meat to eat, and covering for their bodies, but also houses to dwell in, and boats to sail in, so that in case of necessity they could live solely from it. The seals flesh (together with the rein-deer, which has already grown pretty

4 H

scarce)

Phoca,

Pennant's
British
Zoology.

Phoca.

scarce) supplies the natives with their most palatable and substantial food. Their fat furnishes them with oil for lamp-light, chamber and kitchen fire; and whoever sees their habitations, presently finds, that if they even had a superfluity of wood, it would not do, they can use nothing but train in them. They also mollify their dry food, mostly fish, in the train; and finally, they barter it for all kinds of necessaries with the factor. They can sew better with fibres of the seals sinews than with thread or silk. Of the skins of the entrails they make their windows, curtains for their tents, shirts, and part of the bladders they use at their harpoons; and they make train bottles of the maw. Formerly, for want of iron, they made all manner of instruments and working tools of their bones. Neither is the blood wasted, but boiled with other ingredients, and eaten as soup. Of the skin of the seal they stand in the greatest need; for, supposing the skins of rein-deer and birds would furnish them with competent clothing for their bodies, and coverings for their beds; and their flesh, together with fish, with sufficient food; and provided they could dress their meat with wood, and also new model their house-keeping, so as to have light, and keep themselves warm with it too; yet without the sealskins they would not be in a capacity of acquiring these same rein deer, fowls, fishes, and wood; because they must cover over with seal-skin both their large and small boats in which they travel and seek their provision. They must also cut their thongs or straps out of them, make the bladders for their harpoons, and cover their tents with them; without which they could not subsist in summer.

"Therefore no man can pass for a right Greenlander who cannot catch seals. This is the ultimate end they aspire at, in all their device and labour from their childhood up. It is the only art (and in truth a difficult and dangerous one it is) to which they are trained from their infancy; by which they maintain themselves, make themselves agreeable to others, and become beneficial members of the community."

"The Greenlanders have three ways of catching seals: either singly, with the bladder; or in company, by the clapper-hunt; or in the winter on the ice: whereto may be added the shooting them with a gun.

"The principal and most common way is the taking them with the bladder. When the Greenlander sets out equipped, and spies a seal, he tries to surprise it unawares, with the wind and sun in his back, that he may not be heard or seen by it. He tries to conceal himself behind a wave, and makes hastily but softly up to it, till he comes within four, five, or six fathom of it; meanwhile he takes the utmost care that the harpoon, line, and bladder, lie in proper order. Then he takes hold of the oar with his left hand, and the harpoon with his right by the hand-board, and so away he throws it at the seal, in such a manner that the whole dart flies from the hand-board, and leaves that in his hand. If the harpoon hits the mark, and buries itself deeper than the barbs, it will directly disengage itself from the bone-joint, and that from the shaft; and also unwind the string from its lodge on the kajak. The moment the seal is pierced, the Greenlander must throw the bladder, tied to the end of the

Phoca. string, into the water, on the same side as the seal runs and dives; for that he does instantly like a dart. Then the Greenlander goes and takes up the shaft swimming on the water, and lays it in its place. The seal often drags the bladder with it under water, tho' it is a considerable impediment, on account of its great bigness; but it so wearies itself out with it, that it must come up again in about a quarter of an hour to take breath. The Greenlander hastens to the spot where he sees the bladder rise up, and smites the seal as soon as it appears with a great lance. This lance always comes out of its body again; but he throws it at the creature afresh every time it comes up till it is quite spent. Then he runs the little lance into it, and kills it outright, but stops up the wound directly to preserve the blood; and lastly, he blows it up, like a bladder, betwixt skin and flesh, to put it into a better capacity of swimming after him; for which purpose he fastens it to the left side of his kajak or boat.

"In this exercise the Greenlander is exposed to the most and greatest danger of his life; which is probably the reason that they call this hunt or fishery *kamarveck*, i. e. "the extinction," viz. of life. For if the line should entangle itself, as it easily may, in its sudden and violent motion; or if it should catch hold of the kajak, or should wind itself round the oar, or the hand, or even the neck, as it sometimes does in windy weather; or if the seal should turn suddenly to the other side of the boat, it cannot be otherwise than that the kajak must be overturned by the string, and drawn down under water. On such desperate occasions the poor Greenlander stands in need of every possible art to disentangle himself from the string, and to raise himself up from under the water several times successively; for he will continually be overturning till he has quite disengaged himself from the line. Nay, when he imagines himself to be out of all danger, and comes too near the dying seal, it may still bite him in the face or hand; and a female seal that has young, instead of flying the field, will sometimes fly at the Greenlander in the most vehement rage, and do him a mischief, or bite a hole in his kajak that he must sink.

"In this way, singly, they can kill none but the careless stupid seal called *attarfoak*. Several in company must pursue the cautious *kassigiak* by the clapper-hunt. In the same manner they also surround and kill the *attarfoit* in great numbers at certain seasons of the year for in autumn they retire into the creeks or inlets in stormy weather, as in the *Nepiset* found in Ball's river, between the main land and the island *Kangek*, which is full two leagues long, but very narrow. There the Greenlanders cut off their retreat, and frighten them under water by shouting, clapping, and throwing stones; but as they must come up again continually to draw breath, then they persecute them again till they are tired, and at last are obliged to stay so long above water that they surround them, and kill them with a kind of dart for the purpose. During this hunt we have a fine opportunity to see the agility of the Greenlanders, or, if I may call it so, their hussar-like manœuvres. When the seal rises out of the water, they all fly upon it as if they had wings, with a desperate noise; the poor creature is forced to dive again directly; and the moment he does they dis-

* Hist. Greenl. i. 130.

Phoca.

perfe again as faft as they came, and every one gives heed to his poft to fee where it will ftart up again; which is an uncertain thing, and is commonly three quarters of a mile from the former fpot. If a feal has a good broad water, three or four leagues each way, it can keep the fportfmen in play for a couple of hours before it is fo fpent that they can furround and kill it. If the feal in its fright betakes itfelf to the land for a retreat, it is welcomed with fticks and ftones by the women and children, and prefently pierced by the men in the rear. This is a very lively and a very profitable diversion for the Greenlanders, for many times one man will have eight or ten feals for his fhare.

“ The third method of killing feals upon the ice is moftly praftifed in Disko, where the bays are frozen over in the winter. There are feveral ways of proceeding. The feals themfelves make fometimes holes in the ice; where they come and draw breath; near fuch a hole a Greenlander feats himfelf on a ftool, putting his feet on a lower one to keep them from the cold. Now when the feal comes and puts its nofe to the hole, he pierces it inftantly with his harpoon; then breaks the hole larger, and draws it out and kills it quite. Or a Greenlander lays himfelf upon his belly on a kind of a fledge, near other holes, where the feals come out upon the ice to bask themfelves in the fun. Near this great hole they make a little one, and another Greenlander puts a harpoon into it with a very long fhafit or pole. He that lies upon the ice looks into the great hole till he fees a feal coming under the harpoon; then he gives the other the fignal, who runs the feal through with all his might.

“ If the Greenlander fees a feal lying near its hole upon the ice, he fides along upon his belly towards it, wags his head, and grunts like a feal; and the poor feal, thinking it is one of its innocent companions, lets him come near enough to pierce it with his long dart. When the current wears a great hole in the ice in the fpring, the Greenlanders plant themfelves all round it, till the feals come in droves to the brim to fetch breath, and then they kill them with their harpoons. Many alfo are killed on the ice while they lie fleeping and fnooring in the fun.”

To this long quotation, which we think both curious and interefing, we fhall fubjoin the following obfervations of Mr Pennant, which are not lefs worthy of attention.

“ Nature (fays this intelligent writer) has been fo niggardly in providing variety of provision for the Greenlanders, that they are neceffitated to have recourfe to fuch which is offered to them with a liberal hand. The Kamtschatkan nations, which enjoy feveral animals, as well as a great and abundant choice of fifh, are fo enamoured with the tafte of the fat of feals, that they can make no feaft without making it one of the difhes. Of that both Rufians and Kamtschatkans make their candles. The latter eat the flefh boiled, or elfe dried in the fun. If they have a great quantity, they preferve it in the following manner:

“ They dig a pit of requifite depth, and pave it with ftones; then fill it with wood, and fet it on fire fo as to heat the pit to the warmth of a ftove. They then collect all the cinders into a heap. They ftrew the bottom with the green wood of alder, on which they place feperately the flefh and the fat, and put

between every layer branches of the fame tree; when the pit is filled they cover it with fods, fo that the vapour cannot efcape. After fome hours they take out both fat and flefh, and keep it for winter's provisions, and they may be preferved a whole year without fpoiling.

“ The Kamtschatkans have a moft fingular ceremony. After they take the flefh from the heads of the feals, they bring a vefel in form of a canoe, and fling into it all the ftulls, crowned with certain herbs, and place them on the ground. A certain perfon enters the habitation with a fack filled with *tonchiche*, fweet herbs, and a little of the bark of willow. Two of the natives then roll a great ftone towards the door, and cover it with pebbles; two others take the fweet herbs and difpofe them, tied in little packets. The great ftone is to fignify the fea-ftore, the pebbles the waves, and the packets feals. They then bring three difhes of a hath called *tolkoucha*: of this they make little balls, in the middle of which they ftick the packets of herbs: of the willow-bark they make a little canoe, and fill it with *tolkoucha*, and cover it with the fack. After fome time the two Kamtschatkans, who had put the mimic feals into the *tolkoucha*, take the balls, and a vefel refembling a canoe, and draw it along the fand as if it was on the fea, to convince the real feals how agreeable it would be to them to come among the Kamtschatkans, who have a fea in their very jurts or dwellings. And this they imagine will induce the feals to fuffer themfelves to be taken in great numbers. Various other ceremonies, equally ridiculous, are praftifed; in one of which they invoke the winds, which drive the feals on their fhores, to be propitious.

“ Befides the ufes which are made of the flefh and fat of feals, the skins of the largeft are cut into foles for fhoes. The women make their fummer boots of the undrefsed skins, and wear them with the hair outmoft. In a country which abounds fo greatly in furs, very little more ufe is made of the skins of feals in the article of drefs than what has been mentioned. But the Koriaks, the Oloutores, and Tehutfchi, form with the skins canoes and vefels of different fizes, fome large enough to carry thirty people.

“ Seals fwarm on all the cofts of Kamtschatka, and will go up the rivers eighty verfts in purfuit of fifh. The tungufi give the milk of thefe animals to their children inftead of phyfic. The navigators obferved abundance of feals about Bering's ifland, but that they decreafed in numbers as they advanced towards the ftraits; for where the walrufes abounded, the feals grew more and more fcarce.

“ I did not obferve any feal fkin garments among thofe brought over by the navigators, fuch as one might have expected among the Efquimaux of the high latitudes they vifited, and which are fo much in ufe with thofe of Hudfon's Bay and Labrador. That fpecies of drefs doubtlefs was worn in the earlieft times. Thefe people wanted their hiftorians; but we are affured that the Mailagete clothed themfelves in the skins of feals. They, according to D'Anville, inhabited the country to the eaft of the Cafpian fea, and the lake Ara, both of which waters abound with feals.

“ Seals are now become a great article of commerce. The oil from the vail whales is no longer equal to the demand for fupplying the magnificent profufion of

Phoca.

Arctic
Zoology,
v. 1.

Phoca.

lamps in and round our capital. The chase of these animals is redoubled for that purpose; and the skins, properly tanned, are in considerable use in the manufactory of boots and shoes."

4. The phoca barbata, or great seal, has long white whiskers with curled points. The back is arched; hair black, very deciduous, and very thinly dispersed over a thick skin, which is almost naked in summer. The teeth of this species are like those of the common seal; the fore feet are like the human hand, the middle toe being the longest and the thumb short. They are upwards of 12 feet long.

The inhabitants of Greenland cut out of the skin of this species thongs and lines, a finger-thick, for the seal-filbery. Its flesh is as white as veal, and is esteemed the most delicate of any. They produce plenty of lard, but very little oil. The skins of the young are sometimes used to lie on. It inhabits the high sea about Greenland, is very timid, and commonly rests on the floating ice. It breeds about the month of March, and brings forth a single young on the ice, generally among the islands; for then it approaches a little nearer to the land. The great old ones swim very slowly.

On the northern coast of Scotland is found a seal twelve feet long. A young one, seven feet and a half long, was shown in London some years ago, which was so far from maturity as to have scarcely any teeth: yet the common seals have them complete before they attain the size of six feet, their utmost growth.

A species larger than an ox was found in the Kamtschatkan seas from 56 to 64 north latitude, called by the natives *Lehtak* †. They weighed 800 pounds, and were eaten by Bering's crew; but their flesh was very loathsome ‡. The cubs are entirely black.

Steller has given accounts of other seals found in these wild seas; but his descriptions are so very imperfect as to render it impossible to ascertain the species. He speaks in his MSS. of a middle sized kind, wholly and most elegantly spotted; of another which is black with brown spots, having the belly of a yellowish white, and as large as a yearling ox. He mentions a third species, black, and with a particular formation of the hinder legs; and a fourth of a yellowish colour, with a great circle on it of the colour of cherries ||.

5. The phoca foetida, or rough seal, is distinguished by a short nose and short round head; a body almost elliptical, covered with lard almost to the hind feet. This species seldom if ever exceeds four feet in length. Their hairs are closely set together, soft, long, and somewhat erect, intermixed with curled. They are of a dusky colour, mixed with white, which sometimes varies to white, with a dusky dorsal line.

This species never frequents the high seas, but keeps on the fixed ice in the remote bays near the frozen land; and when old never forsakes its haunts. They couple in June, and bring forth in January on the fixed ice, its proper element. In that cold situation they have a hole for the benefit of fishing; near which they generally remain solitary, being rarely found in pairs. They are very inconstant, and often sleep on the surface of the water, by which means they become an easy prey to the eagle. They feed on small fish, shrimps, &c. The skin, tendons, and lard, are used in the same

way with those of other seals. The flesh is red and fetid, especially in males, which is nauseated even by the inhabitants of Greenland.

The seal hunters in Newfoundland have a larger kind, which they call the *square phipper*, and which weighs 500 pounds. Its coat is like that of a water-dog; so that it appears by the length of its hair to be allied to this species; but the vast difference in size admits not of certainty in this respect.

6. The phoca leporina, or leporine seal, has hair of a dirty white colour, tinged with yellow, but never spotted. The hairs are erect, interwoven, and soft like those of a hare especially in the young. The head is long; the upper lip swelling and thick; the whiskers very strong and very thick, ranged in 15 rows, covering the whole front of the lip, so that it appears bearded; the eyes are blue, and the pupil of them black; the teeth are strong; the fore-feet are short; the membranes of the hind feet are even and not waved; the tail is short and thick, it being four inches two lines in length; the cubs are of a milk white colour. The length of this species is about six feet six inches, and the circumference where greatest five feet two.

This species inhabits the White Sea in the summer time, and ascends and descends the mouths of rivers with the tide in quest of prey. It is likewise found on the coasts of Iceland, and within the polar circle from Spitzbergen to Tchutki Nofs, and from thence southward about Kamtschatka.

There are several other species of this genus, and a variety of curious particulars respecting them, which our limits permit us not to give. Such of our readers, however, as wish for further information on this subject, will find themselves amply gratified by a careful perusal of what Mr Pennant has written on the subject, from whose labours we have extracted much of our article. See his *History of Quadrupeds*, Vol. II. p. 518—536 his *Arctic Zoology*, Vol. I. p. 151—177. and his *British Zoology*, as also the several authors whose works he quotes.

PHOCÆA, the last town of Ionia, (Mela, Pliny); of Æolis, (Ptolemy), because situated on the right or north side of the river Hermus, which he makes the boundary of Æolis to the south. It stood far in the land, on a bay or arm of the sea; had two very safe harbours, the one called *Lampter* the other *Nausathmos*, (Livy). It was a colony of Ionians, situated in the territory of Æolis, (Herodotus). Massilia in Gaul was again a colony from it. *Phocœnsis*, the people, (Livy); *Phocœicus*, the epithet, (Lucan); applied to *Marseilles*. It was one of the 12 cities which assembled in the panionium or general council of Ionia.

Some writers tell us, that while the foundations of Ancient this city were lying there appeared near the shore a great shoal of sea calves; whence it is called *Phocœa*, the word *phoca* signifying in Greek a *sea-calf*. Ptolemy, who makes the river Hermus the boundary between Æolia and Ionia, places Phocœa in Æolis; but all other geographers reckon it among the cities of Ionia. It stood on the sea coast, between Cuma to the north, and Smyrna to the south, not far from the Hermus; and was, in former times, one of the most wealthy and powerful cities of all Asia; but is now a poor

Phocæa. poor beggarly village, though the see of a bishop. The Phocæans were expert mariners, and the first among the Greeks that undertook long voyages; which they performed in galleys of fifty oars. As they applied themselves to trade and navigation, they became acquainted pretty early with the coasts and islands of Europe, where they are said to have founded several cities, namely, Velia in Italy; Alalia, or rather Aleria, in Corsica, and Marseilles in Gaul. Neither were they unacquainted with Spain; for Herodotus tells us, that, in the time of Cyrus the Great, the Phocæans arriving at Sartessus, a city in the bay of Cadiz, were treated with extraordinary kindness by Arganthonius king of that country; who, hearing that they were under no small apprehension of the growing power of Cyrus, invited them to leave Ionia, and settle in what part of his kingdom they pleased. The Phocæans could not be prevailed upon to forsake their country; but accepted a large sum of money, which that prince generously presented them with, to defray the expence of building a strong wall round their city. The wall they built on their return; but it was unable to resist the mighty power of Cyrus, whose general Harpagus, inviting the city with a numerous army, soon reduced it to the utmost extremities. The Phocæans, having no hopes of any succour, offered to capitulate; but the conditions offered by Harpagus seeming severe, they begged he would allow them three days to deliberate; and, in the mean time, withdraw his forces. Harpagus, tho' not ignorant of their design, complied with their request. The Phocæans, taking advantage of this condescension, put their wives, children, and all their most valuable effects, on board several vessels which they had ready equipped, and conveyed them safe to the island of Chios, leaving the Persians in possession of empty houses. Their design was to purchase the Cnesian islands, which belonged to the Chians, and settle there. But the Chians not caring to have them so near, lest they should engross all the trade to themselves, as they were a sea-faring people, they put to sea again; and, having taken Phocæa, their native country, by surprise, put all the Persians they found in it to the sword. They went to Corsica; great part of them however returned very soon, as did the rest also in a few years. They then lived in subjection either to the Persians, or tyrants of their own. Among the latter we find mention made of Laodamus, who attended Darius Hytaspis in his expedition against the Scythians; and of Dionysius, who, joining Aristagoras, tyrant of Miletus, and chief author of the Ionian rebellion, retired, after the defeat of his countrymen, to Phœnicia, where he made an immense booty, seizing on all the ships he met with trading to that country. From Phœnicia he sailed to Sicily, where he committed great depredations on the Carthaginians and Tuscans; but is said never to have molested the Greeks.

In the Roman times the city of Phocæa sided with Antiochus the Great; whereupon it was besieged, taken, and plundered, by the Roman general; but allowed to be governed by its own laws. In the war which Aristoniceus brother to Attalus, king of Pergamus, raised against the Romans, they assisted the former to the utmost of their power; a circumstance which so displeased the senate, that they commanded the town to be demolished, and the whole race of the Phocæans

to be utterly rooted out. This severe sentence would have been put in execution, had not the Maffilienses, a Phocæan colony, interposed, and, with much difficulty, alluaged the anger of the senate. Pompey declared Phocæa a free city, and restored the inhabitants to all the privileges they had ever enjoyed; whereas, under the first emperors, it was reckoned one of the most flourishing cities of all Asia Minor. This is all we have been able to collect from the ancients touching the particular history of Phocæa.

PHOCAS, a Roman centurion, was raised to the dignity of emperor by the army, and was crowned at Constantinople about the year 603. The emperor Mauritius, who was thus deserted both by the army and the people, fled to Chalcedon with his five children whom Phocas caused to be inhumanly murdered before his eyes, and then he murdered Mauritius himself, his brother, and several other persons who were attached to that family.

Phocas, thus proclaimed and acknowledged at Constantinople, sent, according to custom, his own image and that of his wife Leontia to Rome, where they were received with loud acclamations, the people there being incensed against Mauritius on account of the cruel exactions of the exarchs, and his other ministers in Italy. Gregory, surnamed the Great, then bishop of Rome, caused the images to be lodged in the oratory of the martyr Celsus, and wrote letters to the new emperor, congratulating him upon his advancement to the throne, which he said was effected by a particular providence, to deliver the people from the innumerable calamities and heavy oppressions under which they had long groaned. Had we no other character of Phocas and Leontia but that which has been conveyed to us in Gregory's letters, we should rank him amongst the best princes mentioned in history; but all other writers paint him in quite different colours; and his actions, transmitted to us by several historians, evidently speak him a most cruel and blood-thirsty tyrant. He was of a middling stature, says Cedrenus, deformed, and of a terrible aspect: His hair was red, his eye-brows met, and one of his cheeks was marked with a scar, which, when he was in a passion, grew black and frightful: he was greatly addicted to wine and women, blood-thirsty, inexorable, bold in speech, a stranger to compassion, in his principles a heretic. He endeavoured, in the beginning of his reign, to gain the affections of the people by celebrating the Circensian games with extraordinary pomp, and distributing on that occasion large sums amongst the people; but finding that instead of applauding they reviled him as a drunkard, he ordered his guards to fall upon them. Some were killed, many wounded, and great numbers were dragged to prison: but the populace rising, set them at liberty, and thenceforth conceived an irreconcilable aversion to the tyrant.

As soon as the death of Mauritius was known, Naries, who then commanded the troops quartered on the frontiers of Persia, revolted. Phocas, however, managed matters so as to gain him over to his interest, and then treacherously and cruelly burnt him alive. He endeavoured to strengthen his cause by respectable alliances; but his cruelty was such as to render him generally hated, for he spared neither sex nor age, and amongst others he murdered Constantina the widow of

Mauritius, and her daughters. These cruelties were at length the cause of his downfall. He became universally hateful; and persons in great authority near his person conspired against him. This conspiracy, however, was discovered, and the persons concerned in it were all put to death. The following year, however, 610, he was overtaken by the fate he had so long deserved.

Heraclius, the son of the governor of Africa, who bore the same name, taking upon him the title of emperor, and being acknowledged as such by the people of Africa, sailed from thence with a formidable fleet, and a powerful army on board, for Constantinople, while Nicetas marched thither by way of Alexandria and the Pentapolis. Heraclius steered his course to Abydus, where he was received with great demonstrations of joy by several persons of rank, who had been banished by Phocas. From Abydus he sailed to Constantinople, where he engaged and utterly defeated the tyrant's fleet. Phocas took refuge in the palace; but one Photinus, whose wife he had formerly debauched, pursuing him with a party of soldiers, forced the gates, dragged the cowardly emperor from the throne, and having stripped him of the imperial robes, and clothed him with a black vest, carried him in chains to Heraclius, who commanded first his hands and feet, then his arms, and at last his head, to be cut off: the remaining part of his body was delivered up to the soldiers, who burnt it in the forum. We are told, that Heraclius having reproached him with his evil administration, he answered, with great calmness, "It is incumbent upon you to govern better." Such was the end of this cruel tyrant, after he had reigned seven years and some months.

PHOCILIDES, a Greek poet and philosopher of Miletus, flourished about 540 years before the Christian era. The poetical piece now extant, attributed to him, is not of his composition, but of another poet who lived in the reign of Adrian.

PHOCION was a distinguished Athenian general and orator in the time of Philip II. of Macedon. His character is thus described in the *Ancient Universal History*. "He was too modest to solicit command, nor did he promote wars that he might raise his authority by them; though, taken either as a soldier, orator, statesman, or general, he was by far the most eminent Athenian of his time. As he was a most disinterested patriot, he could entertain no great affection for Philip: but as he perfectly well knew the disposition of his countrymen, and how unlikely they were long to support such measures as were necessary to humble the Macedonian power, he did not express himself vehemently, but chose rather to cultivate the esteem which on all occasions Philip showed for the state of Athens, as a mean of preserving her, when she should be reduced to that situation which he conceived they wanted virtue to prevent. From this character the reader will easily discern that Demosthenes and he could not well agree. The former was always warm, his language copious, and his designs extensive; and Phocion, on the other hand, was of a mild temper, delivered his opinion in very few words, and proposed schemes at once necessary and easy to be effected. Yet he seldom or never concurred with the people, but

spoke as poignantly against their vices as Demosthenes himself; inasmuch that this orator once told him, 'The Athenians, Phocion, in some of their mad fits, will murder thee.' 'The same (answered he) may fall to thee, Demosthenes, if ever they come to be sober.'

He was afterwards appointed to command the army which was sent to assist the Byzantines against Philip, whom he obliged to return to his own dominions. This truly great man, whom (though extremely poor) no sum could bribe to betray his country, and who at every risk on all occasions gave them sound advice, was at length accused by his ungrateful countrymen. This event happened in the year before Christ 318. He was sent to Athens by Polyperchon head of a faction in Macedonia, together with his friends, chained in carts, with this message, "That though he was convinced they were traitors, yet he left them to be judged by the Athenians as a free people." Phocion demanded whether they intended to proceed against him by form of law; and some crying out that they would, Phocion demanded how that could be if they were not allowed a fair hearing? but perceiving by the clamour of the people, that no such thing was to be expected, he exclaimed, "As for myself, I confess the crime objected to me, and submit to the judgment of the law; but consider, O ye Athenians, what have these poor innocent men done that they should be involved in the same calamity with me?" The people replied with great vociferation, "They are your accomplices, and that is enough." Then the decree was read, adjudging them all to death, viz. Phocion, Nicocles, Aheudippus, Agamon, and Pythocles; these were present: Demetrius, Phalereus, Callimedon, Charicles, and others, were condemned in their absence. Some moved that Phocion might be tortured before he was put to death; nay, they were for bringing the rack into the assembly, and torturing him there. The majority, however, thought it enough if he was put to death, for which the decree was carried unanimously; some putting on garlands of flowers when they gave their votes. As he was going to execution, a person who was his intimate friend asked him if he had any message for his son? "Yes," replied Phocion; "tell him it is my last command that he forget how ill the Athenians treated his father."

The spleen of his enemies was not extinguished with his life: they passed a decree whereby his corpse was banished the Athenian territories; they likewise forbade any Athenians to furnish fire for his funeral pile. One Conopian took up the corpse, and carried it beyond Eleusina, where he borrowed some fire of a Megarian woman and burned it. A Megarian matron, who attended with her maid, raised on the place an honorary monument; and having gathered up the bones, carried them home, and buried them under her own hearth; praying at the same time thus to the Penates: "To you, O ye gods, guardians of this place, I commit the precious remains of the most excellent Phocion. Protect them, I beseech you, from all insults; and deliver them one day to be repositied in the sepulchre of his ancestors, when the Athenians shall become wiser." It was not long before this opportunity occurred. When the Athenians began to cool a little, and remember

Phocion.

Ancient
Univ. Hist.
v. 5.

Phocis. the many services they had received from Phocion, they decree him a statue of brass; ordered his bones to be brought back at the public expence; and decreed that his accusers should be put to death. Agnonides, who was principally concerned in that tragedy, suffered; but Epicurus and Demophilus, who were also accomplices in it, fled. However, Phocion's son met with them, and executed his revenge upon them; which was almost the only good action he ever performed, as he had a very small share of his father's abilities, and not any of his virtues. Such is the fickleness and such the injustice of popular governments; failings which, if we are to judge from universal experience, are absolutely inseparable from them.

PHOCIS, (Demosthenes, Strabo, Pausanias); a country of Greece, contained between Bœotia to the east and Locris to the west, but extending formerly from the Sinus Corinthiacus on the south to the sea of Eubœa on the north, and, according to Dionysius, as far as Thermopylæ; but reduced afterwards to narrower bounds. *Phocenses*, the people; *Phocius* the epithet, (Justin); *Bellum Phocium*, the sacred war which the Thebans and Philip of Macedon carried on against them for plundering the temple at Delphi; and by which Philip paved the way to the sovereignty of all Greece, (Justin.) Its greatest length was from north to south, that is, from $38^{\circ} 45'$ to $39^{\circ} 20'$, or about 35 miles; but very narrow from east to west, not extending to 30 miles, that is, from $23^{\circ} 10'$ to $23^{\circ} 40'$ at the widest, but about 23 miles towards the Corinthian bay, and much narrower still towards the north. This country is generally allowed to have taken its name from Phocus the son of Ornytion, a native of Corinth; but having been soon after invaded by the Eginetæ, under the conduct of another Phocus, who was the son of Eacus king of Enopia, the memory of the first insensibly gave way to that of the second.

In Phocis there were many celebrated mountains, such as Cythæron HELICON, and PARNASSUS. The last two we have already noticed in the order of the alphabet. Cythæron was consecrated to the muses as well as the other two, and was consequently much celebrated by the poets. Both it and Helicon contend with mount Parnassus for height and magnitude. There were no remarkable rivers in Phocis except Cephissus, which runs from the foot of Parnassus northward, and empties itself in the Pindus, which was near the boundary of that kingdom. It had several very considerable cities; such as Cyrra, Crissa, and ANTECYRA, which, according to Ptolemy, were on the sea coasts; and Pythia Delphi, Daulis, Elatia, Ergothenia, and Baulia, which were inland towns. Elatia was the largest and richest after Delphi.

Deucalion was king of that part of Phocis which lies about Parnassus, at the time that the Cecrops flourished in Attica; but the Phocians afterwards formed themselves into a commonwealth, to be governed by their general assemblies, the members of which were chosen from among themselves, and were changed as often as occasion required. Of the history of the Phocians but little is known till the time of the holy war, of which we have the following account in the Ancient Universal History.

“ The Phocians having presumed to plough the territories of the city of Cyrra, consecrated to the Delphic god, were summoned by the other Grecian states before the court of the Amphictyons, where a considerable fine was imposed upon them for their sacrilege. They refused to pay it, on pretence that it was too large; and, at the next assembly their dominions were adjudged confiscated to the use of the temple. This second sentence exasperated the Phocians still more; who, at the instigation of one Philomelus, or, as he is called by Plutarch, Philomedes, seized upon the temple, plundered it of its treasure, and held the sacred depositum for a considerable time. This second crime occasioned another assembly of the Amphictyons, the result of which was a formal declaration of war against the Phocians. The quarrel being become more general, the several states took part in it according to their inclinations or interest. Athens, Sparta, and some others of the Peloponnesians, declared for the Phocians; and the Thebans, Thessalians, Locrians, and other neighbouring states, against them. A war was commenced with great fury on both sides, and styled *the holy war*, which lasted ten years; during which the Phocians, having hired a number of foreign troops, made an obstinate defence, and would in all probability have held out much longer had not Philip of Macedon given the finishing stroke to their total defeat and punishment. The war being ended, the grand council assembled again, and imposed an annual fine of 60 talents upon the Phocians, to be paid to the temple, and continued till they had fully repaired the damage it had sustained from them; and, till this reparation should be made, they were excluded from dwelling in walled towns, and from having any vote in the grand assembly. They did not, however, continue long under this heavy sentence: their known bravery made their assistance so necessary to the rest, that they were glad to remit it; after which remission they continued to behave with their usual courage and resolution, and soon obliterated their former guilt.”

We cannot finish this article without mentioning more particularly Daulis, rendered famous, not so much for its extent or richness, as for the stature and prowess of its inhabitants; but still more for the inhuman reward which was served up to Tereus king of Thrace by the women of this city, by whom he was soon after murdered for the double injury he had done to his sister-in-law Philomela, daughter of Pandion king of Athens. See PHILOMELA.

PHŒBUS, one of the names given by ancient mythologists to the Sun, Sol, or Apollo. See APOLLO.

PHŒNICIA, or more properly PHŒNICE, the ancient name of a country lying between the 34th and 36th degrees of north latitude; bounded by Syria on the north and east, by Judea on the south, and by the Mediterranean on the west. Whence it borrowed its name is not absolutely certain. Some derive it from one Phœnix; others from the Greek word *phanix*, signifying a *palm* or *date*, as that tree remarkably abounded in this country. Some again suppose that Phœnice is originally a translation of the Hebrew word *Edom*, from the Edomites who fled thither in the days of David. By the contraction of Canaan it was also called

Phocis

Phœnicia.

Phœnicia, called *Chana*, and anciently *Rhabbothin* and *Colpitis* (A). The Jews commonly named it *Canaan*; though some part of it, at least, they knew by the name of *Syro-phœnicæ* (B). Bochart tells us that the most probable etymology is *Phœne Anak*, i. e. "the descendents of Anak." Such were the names peculiar to this small country; though Phœnicæ was sometimes extended to all the maritime countries of Syria and Judæa, and *Canaan* to the Philistines, and even to the Amalekites. On the contrary, these, two names, and the rest, were most generally swallowed up by those of Palestine and Syria (C).

There is some disagreement among authors with respect to the northern limits of this country. Ptolemy makes the river Eleutherus the boundary of Phœnicæ to the north; but Pliny, Mela, and Stephanus, place it in the island of Aradus, lying north of that river. Strabo observes, that some will have the river Eleutherus to be the boundary of Seleucis, on the side of Phœnicæ and Cœlœsyria. On the coast of Phœnicæ, and south of the river Eleutherus, stood the following cities: SIMYRA, OUTHOSIA, TRIPOLIS, BOTRYS, BYBLUS, PALÆBYBLUS, BERYTUS, SIDON, SAREPTA, TYRUS, PALÆTYRUS.

Phœnicæ extended, according to Ptolemy, even beyond Mount Carmelus; for that geographer places in Phœnicæ not only Ecdippa and Ptolemais, but Sycaminum and Dara, which stand south of that mountain. These, however, properly speaking, belonged to Palestine. We will not take upon us to mark out the bounds of the midland Phœnicæ. Ptolemy reckons in it the following towns; Arca, Palæbyblus (Old Byblus), Gabila, and Cæsaria Panice. This province was considerably extended in the times of Christianity; when, being considered as a province of Syria, it included not only Damascus but Palmyra also.

The soil of this country is good, and productive of many necessaries for food and clothing. The air is wholesome, and the climate agreeable. It is plentifully watered by small rivers; which, running down from mount Libanus, sometimes swell to an immoderate degree, either increased by the melting of the snows on that mountain, or by heavy rains. Upon these occasions they overflow, to the great danger and hinderance of the traveller and damage of the country. Among these rivers is that of *APONIS*.

It is universally allowed that the Phœnicians were Canaanites (D) by descent: nothing is plainer or less

Phœnicia, contested, and therefore it were time lost to prove it. We shall only add, that their blood must have been mixed with that of foreigners in process of time, as it happens in all trading places: and that many strange families must have settled among them, who could consequently lay no claim to this remote origin, how much soever they may have been called Phœnicians, and reckoned of the same descent with the ancient proprietors.

The Phœnicians were governed by kings; and their territory, as small a slip as it was, included several kingdoms; namely, those of Sidon, Tyre, Aradus, Berytus, and Byblus. In this particular they imitated and adhered to the primitive government of their forefathers; who, like the other Canaanites, were under many petty princes, to whom they allowed the sovereign dignity, reserving to themselves the natural rights and liberties of mankind. Of their civil laws we have no particular system.

With regard to religion, the Phœnicians were the most gross and abominable idolaters. Th Bael-berith, Baelzebub, Baalshamen, &c. mentioned in Scripture, were some of the Phœnician gods; as were also the Moloch, Ashtaroth, and Thammuz, mentioned in the sacred writings.—The word *Baal*, in itself an appellation, was no doubt applied to the true God, until he rejected it on account of its being so much profaned by the idolaters. The name was not appropriated to any particular deity among the idolatrous nations, but was common to many; however, it was generally imagined that one great God presided over all the rest. Among the Phœnicians this deity was named *Baalshamen*; whom the Hebrews would have called *Baalshemim*, or the God of heaven. In all probability this was also the principal Carthaginian deity, though his punice name is unknown. We have many religious rites of the Carthaginians handed down to us by the Greek and Roman writers; but they all bestowed names of their own gods upon those of the Carthaginians, which leads us to a knowledge of the correspondence between the characters of the Phœnician and European deities. The principal deity of Carthage, according to Diodorus Siculus, was Chronus or Saturn. The sacrifices offered up to him were children of the best families. Our author also tells us, that the Carthaginians had a brazen statue or colossus of this god, the hands of which were extended in act to receive, and bent downwards in such a manner, that the child laid thereon

(A) This last name is a translation of the first. *Rabbotten* is in Hebrew a great gulph or bay. From *rabbotten*, by changing the Hebrew *ts* into the Greek *t*, comes *rabbotten*; and, with a little variation, *rhabbothin*. $\kappa\alpha\iota\tau\omicron\upsilon$, *colpos*, is Greek also for a bay or gulph: whence it appears that *colbitis* or *colpites* is a translation of *rabbotten*.

(B) Bochart supposes that the borderers, both upon the Phœnician and Syrian side, were called by the common name of Syrophœnicians, as partaking equally of both nations.

(C) Or rather Phœnicæ, Palestine, and Syria, were promiscuously used for each other, and particularly the two former. Phœnicæ and Palestine, says Stephanus Byzantinus, were the same. As for Syria, we have already observed, that in its largest extent it sometimes comprehended Phœnicæ and Cœlœsyria. Herodotus plainly confounds these three names; we mean, uses one for the other indifferently.

(D) Bochart insinuates that the Canaanites were ashamed of their name, on account of the curse denounced on their progenitor, and terrified by the wars so vigorously and successfully waged on them by the Israelites, purely because they were Canaanites; and that therefore, to avoid the ignominy of the one and the danger of the other, they abjured their old name, and changed it for Phœnicians, Syrians, Syrophœnicians, and Assyrians. Heidegger conjectures also that they were ashamed of their ancestor Canaan.

Phœnicia. thereon immediately fell down into a hollow where there was a fiery furnace. He adds also, that this inhuman practice seemed to confirm a tradition, handed down to the Greeks from very early antiquity, viz. that Saturn devoured his own children.

The goddess Cœlestis, or Urania, was held in the highest veneration by the Carthaginians. She is thought to have been the same with the queen of heaven mentioned in Jeremiah, the Juno Olympia of the Greeks. According to Hesychius, the same word applied in the Punic language both to Juno and Venus: Nay, the ancient Greeks frequently confound Juno, Venus, and Diana or the moon, all together; which is to be attributed to the Egyptians and Phœnicians, from whom they received their system of religion; who seem in the most ancient times to have had but one name for them all. Besides these there were several other deities of later date, who were worshipped among the Phœnicians, particularly those of Tyre, and consequently among the Carthaginians also. These were Jupiter, Apollo, Mars, and Bacchus. Jupiter was worshipped under the name of *Belus* or *Baal*. To him they addressed their oaths; and placed him for the most part, as there is reason to believe, at the head of their treaties. The same name was also given to the other two, whence they were frequently mistaken for one another. Apollo or the sun went either by this name simply, or by others of which this made a part.

The Carthaginian superstition, however, was not confined to these deities alone. They worshipped also the fire, air, and other elements; and had gods of rivers, meads, &c. Nay, they paid divine honours to the spirits of their heroes, and even to men and women themselves while yet in life; and in this adoration Hannibal the Great had for some time a share, notwithstanding the infamous conduct of his countrymen towards him at last. In order to worship those gods with more conveniency on all occasions, the Carthaginians had a kind of portable temples. These were only covered chariots, in which were some small images representing their favourite deities; and which were drawn by oxen. They were also a kind of oracle; and their responses were understood by the motion impressed upon the vehicle. This was likewise an Egyptian or Lybian custom; and Tacitus informs us that the ancient Germans had something of the same kind. The tabernacle of Moloch is thought to have been a machine of this kind; and it is not improbable that the whole was derived from the tabernacle of the Jews in the wilderness.

Besides all the deities above-mentioned, we still find another, named the *Dæmon* or *Genius* of Carthage, mentioned in the treaty made by Philip of Macedon and Hannibal. What this deity might be, we know not; however, it may be observed, that the pagan world in general believed in the existence of demœs, or intelligences who had a kind of middle nature between gods and men, and to whom the administration of the world was in a great measure committed. Hence it is no wonder that they should have received religious honours. For when once mankind were possessed with the opinion that they were the ministers of the gods, and trusted with the dispensation of their favours, as well as the infliction of their punishments, it is natural

to suppose that they would be desirous of making their addresses to them. See *ASTARTE* and *POLYTHEISM*.

Herodotus supposes the Phœnicians to have been circumcised; but Josephus asserts, that none of the nations included under the vague name of Palestine and Syria used that rite, the Jews excepted; so that if the Phœnicians had anciently that custom, they came in time to neglect it, and at length wholly laid it aside. They obtained however from the flesh of swine.

Much is said of their arts, sciences, and manufactures; but as what we find concerning them is couched in general terms only, we cannot descend on particulars. The Sidonians, under which denomination we comprehend the Phœnicians in general, were of a most happy genius. They were from the beginning addicted to philosophical exercises of the mind; inasmuch that a Sidonian, by name of Mosehus, taught the doctrine of atoms before the Trojan war: and Abomenus of Tyre puzzled Solomon by the subtilty of his questions. Phœnicia continued to be one of the seats of learning, and both Tyre and Sidon produced their philosophers of later ages; namely, Boethus and Diodatus of Sidon, Antipater of Tyre, and Apollonius of the same place; who gave an account of the writings and disciples of Zeno. For their language, see *PHILOLOGY*, n^o 61. As to their manufactures, the glass of Sidon, the purple of Tyre, and the exceeding fine linen they wove, were the product of their own country, and their own invention; and for their extraordinary skill in working metals, in hewing timber and stone; in a word, for their perfect knowledge of what was solid, great, and ornamental in architecture—we need only put the reader in mind of the large share they had in erecting and decorating the temple at Jerusalem under their king Hiram. Their taste, design, and ingenious invention, was such, that whatever was elegant, great, or pleasing, whether in apparel, vessels, or toys, was distinguished by way of excellence with the epithet of Sidonian.

The Phœnicians were likewise celebrated as merchants, navigators, and planters of colonies in foreign parts. As merchants, they may be said to have engrossed all the commerce of the western world: as navigators, they were the boldest, the most experienced, and greatest discoverers, of the ancient times; they had for many ages no rivals. In planting colonies they exerted themselves so much, that, considering their habitation was little more than the slip of ground between mount Libanus and the sea, it is surprising how they could furnish such supplies of people, and not wholly depopulate their native country.

It is generally supposed that the Phœnicians were induced to deal in foreign commodities by their neighbourhood with the Syrians, who were perhaps the most ancient of those who carried on a considerable and regular trade with the more eastern regions: and this conjecture appears probable at least; for their own territory was but small, and little able to afford any considerable exports, if we except manufactures: but that their manufactures were any ways considerable till they began to turn all the channels of trade into their own country, it is hard to believe. In Syria, which was a large country, they found store of productions of the natural growth of that soil, and many choice and useful commodities brought from the east. Thus, having

Phœnicia. a safe coast, with convenient harbours, on one side, and excellent materials for ship-building on the other: perceiving how acceptable many commodities that Syria furnished would be in foreign parts, and being at the same time, perhaps, shown the way by the Syrians themselves, who may have navigated the Mediterranean—they turned all their thoughts to trade and navigation, and by an uncommon application soon eclipsed their masters in that art.

It were in vain to talk of the Edomites, who fled hither in David's time; or to inquire why Herodotus supposes the Phœnicians came from the Red Sea: their origin we have already seen. That some of the Edomites fled into this country in the days of David, and that they were a trading people, is very evident: what improvements they brought with them into Phœnicia, it is hard to say; and by the way, it is as difficult to ascertain their numbers. In all probability they brought with them a knowledge of the Red Sea, and of the south parts of Arabia, Egypt, and Ethiopia; and by their information made the Phœnicians acquainted with those coasts; by which means they were enabled to undertake voyages to those parts, for Solomon, and Pharaoh Necho, king of Egypt.

Their whole thoughts were employed on schemes to advance their commerce. They affected no empire but that of the sea; and seemed to aim at nothing but the peaceable enjoyment of their trade. This they extended to all the known parts they could reach; to the British isles, commonly understood by the Cassiterides; to Spain, and other places in the ocean, both within and without the Straits of Gibraltar; and, in general, to all the ports of the Mediterranean, the Black Sea, and the Lake Mæotis. In all these parts they had settlements and correspondents, from which they drew what was useful to themselves, or might be so to others; and thus they exercised the three great branches of trade, as it is commonly divided into importation, exportation, and transportation, in full latitude. Such was their sea trade; and for that which they carried on by land in Syria, Mesopotamia, Assyria, Babylonia, Persia, Arabia, and even in India, it was of no less extent, and may give us an idea of what this people once was, how rich and how deservedly their merchants are mentioned in Scripture as equal to princes. Their country was, at that time, the great warehouse, where every thing that might either administer to the necessities or luxury of mankind was to be found; which they distributed as they judged would be best for their own interest. The purple of Tyre, the glass of Sidon, and the exceeding fine linen made in this country, together with other curious pieces of art in metals and wood, already mentioned, appear to have been the chief and almost only commodities of Phœnicia itself. Indeed their territory was so small, that it is not to be imagined they could afford to export any of their own growth; it is more likely that they rather wanted than abounded with the fruits of the earth.

Having thus spoken in general terms of their trade, we shall now touch upon their shipping and some things remarkable in their navigation. Their larger embarkations were of two sorts; they divided them into round ships or gauli; and long ships, galleys, or triremes. When they drew up in line of battle, the gauli were disposed at a small distance from each other in the

wings, or in the van and the rear: their triremes were contracted together in the centre. If, at any time, they observed that a stranger kept them company in their voyage, or followed in their track, they were sure to get rid of him if they could, or deceive him if possible; in which policy they went so far, as to venture the loss of their ships, and even their lives; so jealous were they of foreigners, and so tenaciously bent on keeping the whole trade to themselves. In order to discourage other nations from engaging in commerce, they practised piracy, or pretended to be at war with such as they met when they thought themselves strongest. This was but a natural stroke of policy in people who grasped at the whole commerce of the then known world. We must not forget here the famous fishery of Tyre, which so remarkably enriched that city in particular. See ASTRONOMY, n^o 7. OPHIR, and TYRE.

PHOENICOPTERUS, or FLAMINGO, in ornithology, a genus of birds belonging to the order of grallæ. The beak is naked, toothed, and bent as if it was broken; the nostrils are linear; the feet are palmated, and four-toed. There is but one species; viz. the Bahamensis of Catesby, a native of Africa and America. Plate CCCXCII.

This bird resembles the heron in shape, excepting the bill, which is of a very singular form. It is two years old before it arrives at its perfect colour; and then it is entirely red, excepting the quill-feathers, which are black. A full-grown one is of equal weight with a wild duck; and when it stands erect, it is five feet high. The feet are webbed. The flesh is delicate; and most resembles that of a partridge in taste. The tongue, above any other part, was in the highest esteem with the luxurious Romans. These birds make their nests on hillocks in shallow water; on which they sit with their legs extended down, like a man sitting on a stool. They breed on the coasts of Cuba and the Bahama islands in the West Indies; and frequent salt-water only. By reason of the particular shape of its bill, this bird, in eating, twists its neck from side to side, and makes the upper mandible touch the ground. They are very stupid, and will not rise at the report of a gun: nor is it any warning to those who survive, that they see others killed by their side; so that, by keeping himself out of sight, a fowler may kill as many as he pleases.

These birds prefer a warm climate. In the old continent they are not often met with beyond 40 degrees north or south. They are met with everywhere on the African coast and adjacent isles, to the Cape of Good Hope; and sometimes on the coasts of Spain, Italy, and those of France lying in the Mediterranean Sea; being at times found at Marseilles, and for some way up the Rhone. In some seasons they frequent Aleppo and the parts adjacent. They are seen also on the Persian side of the Caspian Sea, and from thence along the western coast as far as the Wolga; tho' this is at uncertain times, and chiefly in considerable flocks coming from the north-east, mostly in October and November; but so soon as the wind changes they totally disappear. They breed in the Cape Verd isles, particularly in that of Sal. They go for the most part together in flocks, except in breeding time. Dampier says, that, with two more in company, he killed 14 at once, which was effected by secreting themselves;

Phœnicop-
terus,
Phœnix.

for they are so very shy, that they will by no means suffer any one to approach openly near enough to shoot them. Kolben tells us, that they are very numerous at the Cape; keeping in the day on the borders of the lakes and rivers, and lodging themselves at night in the long grass on the hills. They are also common to various places in the warmer parts of America, frequenting the same latitudes as in other quarters of the world; being found at Peru, Chili, Cayenne, and the coast of Brasil, as well as the various islands of the West Indies. Sloane found them in Jamaica; but particularly at the Bahama Islands and at Cuba, where they breed. When seen at a distance, they appear as a regiment of soldiers, being ranged along-side one another, on the borders of the rivers, searching for food; which chiefly consists of small fish or the eggs of them; and of water-insects, which they search after by plunging in the bill and part of the head, from time to time trampling with their feet to muddy the water, that their prey may be raised from the bottom. Whilst they are feeding, one of them is said to stand sentinel, and the moment he finds the alarm the whole flock takes wing. This bird, when at rest, stands on one leg, the other being drawn up close to the body, with the head placed under the wing on that side of the body it stands on.

They are sometimes caught young, and are brought up tame; but are always impatient of cold: and in this state will seldom live a great while, gradually losing their colour, flesh, and appetite, and dying for want of that food which in a state of nature at large they were abundantly supplied with.

PHOENIX, in astronomy. See there, n^o 406.

PHOENIX, the *Great Palm*, or *Date-tree*; a genus of plants belonging to the order of palmæ. There is only one species, viz. the *dactylifera*, or common date-tree, a native of Africa and the eastern countries, where it grows to 50, 60, and 100 feet high. The trunk is round, upright, and fluted with protuberances, which are the vestiges of the decayed leaves. From the top issues forth a cluster of leaves or branches eight or nine feet long, extending all round like an umbrella, and bending a little towards the earth. The bottom part produces a number of stalks like those of the middle, but seldom shooting so high as four or five feet. These stalks, says Adanson, diffuse the tree very considerably; so that, wherever it naturally grows in forests, it is extremely difficult to open a passage through its prickly leaves. The date tree was introduced into Jamaica soon after the conquest of the island by the Spaniards. There are, however, but few of them in Jamaica at this time. The fruit is somewhat in the shape of an acorn. It is composed of a thin, light, and glossy membrane, somewhat pellucid and yellowish; which contains a fine, soft, and pulpy fruit, which is firm, sweet, and somewhat vinous to the taste, esculent, and wholesome; and within this is inclosed a solid, tough, and hard kernel, of a pale grey colour on the outside, and finely marbled within like the nutmeg. For medicinal use dates are to be chosen large, full, fresh, yellow on the surface, soft and tender, not too much wrinkled; such as have a vinous taste, and do not rattle when shaken. They are produced in many parts of Europe, but never ripen perfectly there. The best are brought from Tunis; they are also very fine and good in Egypt and in many parts of the east.

Those of Spain and France look well; but are never perfectly ripe, and very subject to decay. They are preserved three different ways; some pressed and dry; others pressed more moderately, and again moistened with their own juice; and others not pressed at all, but moistened with the juice of other dates, as they are packed up, which is done in baskets or skins. Those preserved in this last way are much the best. Dates have always been esteemed moderately strengthening and astringent.

Though the date-tree grows every where indiscriminately on the northern coasts of Africa, it is not cultivated with care, except beyond Mount Atlas; because the heat is not sufficiently powerful along the coasts to bring the fruits to proper maturity. We shall here extract some observations from Mr Des Fontaines respecting the manner of cultivating it in Barbary, and on the different uses to which it is applied. All that part of the Zuara which is near Mount Atlas, and the only part of this vast desert which is inhabited, produces very little corn; the soil being sandy, and burnt up by the sun, is almost entirely unfit for the cultivation of grain, its only productions of that kind being a little barley, maize, and fargo. The date tree, however, supplies the deficiency of corn to the inhabitants of these countries, and furnishes them with almost the whole of their subsistence. They have flocks of sheep; but as they are not numerous, they preserve them for the sake of their wool; besides, the flesh of these animals is very unwholesome food in countries that are exceedingly warm; and these people, though ignorant, have probably been enabled by experience to know that it was salutary for them to abstain from it. The date-trees are planted without any order, at the distance of 12 feet one from the other, in the neighbourhood of rivulets and streams which issue from the sand. Forests of them may be seen here and there, some of which are several leagues in circumference. The extent of these plantations depends upon the quantity of water which can be procured to water them; for they require much moisture. All these forests are intermixed with orange, almond, and pomegranate trees, and with vines which twirl round the trunks of the date trees; and the heat is strong enough to ripen the fruit, though they are never exposed to the sun.

Along the rivulets and streams, dykes are erected to stop the course of their waters, in order that they may be distributed amongst the date trees by means of small canals. The number of canals is fixed for each individual; and in several cantons, to have a right to them, the proprietors are obliged to pay an annual sum proportionable to the number and extent of their plantations. Care is taken to till the earth well, and to raise a circular border around the root of each tree, that the water may remain longer and in larger quantity. The date trees are watered in every season, but more particularly during the great heats of summer.

It is generally in winter that new plantations of this tree are formed. For this purpose those who cultivate them take shoots of those which produce the best dates, and plant them at a small distance one from the other. At the end of three or four years these shoots, if they have been properly taken care of, begin to bear fruit; but this fruit is as yet dry, without sweetness,

Phœnix.

Phoenix.

and even without kernels; they never reach the highest degree of perfection of which they are susceptible till they are about 15 or 20 years old.

These plants are however produced from the seeds taken out of the fruit, provided they are fresh. They should be sown in pots filled with light rich earth, and plunged into a moderate hot-bed of tanners bark, which should be kept in a moderate temperature of heat, and the earth frequently refreshed with water. When the plants are come up to a proper size, they should be each planted in a separate small pot, filled with the same light earth, and plunged into a hot bed again, observing to refresh them with water, as also to let them have air in proportion to the warmth of the season and the bed in which they are placed. During the summer-time they should remain in the same hot-bed; but in the beginning of August, they should have a great share of air to harden them against the approach of winter; for if they are too much forced, they will be so tender as not to be preserved through the winter without much difficulty, especially if you have not the conveniency of a bark-stove to keep them in. The soil in which these plants should be placed, must be composed in the following manner, viz. half of light fresh earth taken from a pasture-ground, the other half sea-sand and rotten dung or tanners bark in equal proportion; these should be carefully mixed, and laid in a heap three or four months at least before it is used, but should be often turned over to prevent the growth of weeds, and to sweeten the earth.

The trees, however, which spring from seed never produce so good dates as those that are raised from shoots; they being always poor and ill tasted. It is undoubtedly by force of cultivation, and after several generations, that they acquire a good quality.

The date trees which have been originally sown, grow rapidly, and we have been assured that they bear fruit in the fourth or fifth year. Care is taken to cut the inferior branches of the date tree in proportion as they rise; and a piece of the root is always left of some inches in length, which affords the easy means of climbing to the summit. These trees live a long time, according to the account of the Arabs; and in order to prove it, they say that when they have attained to their full growth, no change is observed in them for the space of three generations.

The number of females which are cultivated is much superior to that of the males, because they are much more profitable. The sexual organs of the date tree grow, as is well known, upon different stalks, and these trees flower in the months of April and May, at which time the Arabs cut the male branches to im-

Phoenix.

pregnate the female. For this purpose, they make an incision in the trunk of each branch which they wish to produce fruit, and place in it a stalk of male flowers; without this precaution the date tree would produce only abortive fruit (A). In some cantons the male branches are only shaken over the female. The practice of impregnating the date tree in this manner is very ancient. Pliny describes it very accurately in that part of his work where he treats of the palm-tree.

There is scarcely any part of the date tree which is not useful. The wood, though of a spongy texture, lasts such a number of years, that the inhabitants of the country say it is incorruptible. They employ it for making beams and instruments of husbandry; it burns slowly, but the coals which result from its combustion are very strong and produce a great heat.

The Arabs strip the bark and fibrous parts from the young date trees, and eat the substance, which is in the centre; it is very nourishing, and has a sweet taste: it is known by the name of the marrow of the date tree. They eat also the leaves, when they are young and tender, with lemon juice; the old ones are laid out to dry, and are employed for making mats and other works of the same kind, which are much used and with which they carry on a considerable trade in the interior parts of the country. From the sides of the stumps of the branches which have been left arise a great number of delicate filaments, of which they make ropes, and which might serve to fabricate cloth.

Of the fresh dates and sugar, says Hasselquist, the Egyptians make a conserve, which has a very pleasant taste. In Egypt they use the leaves as fly-flaps, for driving away the numerous insects which prove so troublesome in hot-countries. The hard boughs are used for fences and other purposes of husbandry; the principal stem for building. The fruit, before it is ripe, is somewhat astringent; but when thoroughly mature, is of the nature of the fig. The Senegal dates are shorter than those of Egypt, but much thicker in the pulp, which is said to have a sugary agreeable taste, superior to that of the best dates of the Levant.

A white liquor, known by the name of *milk*, is drawn also from the date-tree. To obtain it, all the branches are cut from the summit of one of these trees, and after several incisions have been made in it, they are covered with leaves, in order that the heat of the sun may not dry it.

The sap drops down into a vessel placed to receive it, at the bottom of a circular groove, made below the

(A) The celebrated Linnaeus, in his Dissertation on the Sexes of Plants, speaking of the date tree, says, "A female date-bearing palm flowered many years at Berlin without producing any seeds; but the Berlin people taking care to have some of the blossoms of the male tree, which was then flowering at Leipzig, sent to them by the post, they obtained fruit by these means; and some dates, the offspring of this impregnation, being planted in my garden, sprung up, and to this day continue to grow vigorously. Kämpfer formerly told us, how necessary it was found by the oriental people, who live upon the produce of palm trees, and are the true *Lotophagi*, to plant some male trees among the females, if they hoped for any fruit: hence it is the practice of those who make war in that part of the world to cut down all the male palms, that a famine may afflict their proprietors; sometimes even the inhabitants themselves destroy the male trees when they dread an invasion, that their enemies may find no sustenance in the country."

Phoenix. the incisions. The milk of the date tree has a sweet and agreeable taste when it is new; it is very refreshing, and it is even given to sick people to drink, but it generally turns sour at the end of 24 hours. Old trees are chosen for this operation, because the cutting of the branches, and the large quantity of sap which flows from them, greatly exhaust them, and often cause them to decay.

The male flowers of the date tree are also useful. They are eaten when still tender, mixed up with a little lemon juice. They are reckoned to be very provocative: the odour which they exhale is probably the cause of this property being ascribed to them.

These date trees are very lucrative to the inhabitants of the desert. Some of them produce twenty bunches of dates; but care is always taken to lop off a part of them, that those which remain may become larger; ten or twelve bunches only are left on the most vigorous trees.

It is reckoned that a good tree produces, one year with another, about the value of 10 or 12 shillings to the proprietor. A pretty considerable trade is carried on with dates in the interior part of the country, and large quantities of them are exported to France and Italy. The crop is gathered towards the end of November. When the bunches are taken from the tree, they are hung up in some very dry place where they may be sheltered and secure from insects.

Dates afford wholesome nourishment, and have a very agreeable taste when they are fresh. The Arabs eat them without seasoning. They dry and harden them in the sun, to reduce them to a kind of meal, which they lay up in store to supply themselves with food during the long journeys which they often undertake across their deserts. This simple food is sufficient to nourish them for a long time.—The inhabitants of the Zaara procure also from their dates a kind of honey which is exceedingly sweet. For this purpose they choose those which have the softest pulp; and having put them into a large jar with a hole in the bottom, they squeeze them by placing over them a weight of eight or ten pounds.—The most fluid part of the substance, which drops through the hole, is what they call the *honey* of the date.
